CONTENTS.

Librarianship and Scientific Research.

THE growing difficulty of the task of making the ever-expanding mass of published information readily available to workers in every branch of science is a serious problem both in scientific and in industrial research. The value of a uniform international system of classification as the only effective way of dealing with the present enormous output of scientific periodicals was emphasised by most of those who took part in a discussion on the abstracting and classification of scientific literature which followed the annual dinner of the Chemical Engineering Group of the Society of Chemical Industry. Workers on the borderline and in the newer branches of science have suffered most from the absence of a uniform classification, and would gain most immediately by the adoption of the universal decimal classification of the Institut de Bibliographie, of Brussels. This system has already been adopted by a number of reference libraries, including the Science Library, and also in industry, and is used by the Royal Society (for its 'B' papers) and other societies in Great Britain and abroad. So far, the adoption of the international system has not been favoured by the British Bureau of Chemical Abstracts. This is due not to any difficulty in applying the system to the complicated case of chemistry, for the international system allows any chemical compound to be classified, but apparently to doubts as to the value of the system to chemists already familiar with a complicated system of nomenclature.

The adoption of a uniform international system of classification is, however, only a step towards the solution of the problem. A significant feature in the present situation is that in spite of the

excellent abstracting services already available, most, if not all, of the large research associations or departments for scientific or industrial research find it advantageous to issue their own bulletins of abstracts. This is not necessarily a case of overlapping. In the first case, such bulletins will be limited not by sciences but by applications of science, and a particular bulletin of abstracts may cover engineering in several branches, physics, chemistry, and perhaps biology or medicine as they are applied to a particular field of industry. Again, the abstracts in such a bulletin will not be limited to the journals which contain accounts of original work, but will include journals describing applications of such work, etc., and valuable ideas or suggestions are often taken from the technical or trade papers, apart altogether from the commercial information, and other matter that is gathered in this way. Another feature may be the abstracts from patent literature or summaries of work carried out in the department or institution which is not published outside. A bulletin of this kind is essentially a record of current information received in the library, and rarely includes abstracts on the scale of those issued by Science Abstracts or the Bureau of Chemical Abstracts. Its purpose is to stimulate thought and to bring to the notice of those concerned the papers, patents, and other documents, internal or external, which are of immediate interest to them. For this reason, promptitude of publication is an important matter. Such library notes may be in the hands of readers several weeks before the publication even of British Chemical Abstracts, which are noted for their promptness of publication.

One of the points which Major Freeth most stressed in his recent lecture on the influence of technique on research was the isolation of the modern scientific worker. Science lives far too much in water-tight compartments, and frequently men are unaware of first-class work going on within two or three hundred yards of them in another department. This is one result of the extraordinary specialisation of industry and of science, and it persists, if it does not increase, in spite of the widening scope of the abstracting services. The issue of a bulletin of the type just indicated affords a librarian some opportunity of breaking down the isolation of the scientific workers for whom the bulletin is intended. The smaller circle of workers for whom the bulletin is intended permits the issue of a document with rather more personal and vital interest than is possible in the case of one published for scientific workers generally, or even for one class of scientific workers. The shorter abstracts or notes are another advantage. They are much more likely to be read by those to whom it is sent than the lengthier abstracts. Few engaged in scientific or industrial research have not at times been overwhelmed by the mass even of abstracted information which seems to call for attention, and fewer still have diligently and consistently examined the whole. The smaller group of workers also enables the librarian to issue special notices directing the attention of individual workers to papers or publications likely to be of special interest or service to them. In this way a librarian may be able very considerably to assist the director of research who is often responsible for considerably more than the fifteen workers whose investigations he is supposed to be able to direct at maximum efficiency.

The efficient discharge of duties of this type depends very largely upon the personality of the librarian, and a technical librarian is now generally regarded as occupying a key position. His ability to select material for indexing and for issue in bulletin form will be influenced largely by the extent of his practical knowledge of the technical and manufacturing side of the industry. Some such knowledge is fundamental to the specialised work of indexing and classification, and only when the librarian is able to use it in selecting material for his special requirements will industry reap the full value of the International Decimal Classification and improvements in the abstracts issued by the scientific societies.

Under modern conditions a well-equipped and adequately staffed library is an essential feature of any large research department. The increasing volume of scientific literature has indeed enhanced the value of a literature search, and in a recent article* W. A. Hamor and L. W. Bass point to the increasing demand for chemical bibliographers, literature indexers, and the like, as evidence that this is widely recognised. The conditions for literature searches in academic work and in industrial research often differ considerably, and various factors which are emphasised by Hamor and Bass tend to greater thoroughness in the former case, apart from the actual library resources which may be available in the two cases. There is much to be said in support of Dr. S. C. Bradford's suggestion that the preparation of bibliographies or lists of papers dealing with specified subjects should be undertaken by libraries. A literature search is

* "Bibliochresis: The Pilot of Scientific Research", *Science*, 1930, **71**, 375-378.

effected much more thoroughly and rapidly by a trained library staff than by the average research worker. The saving of time for actual research work may be quite considerable enough for the practice of entrusting literature searches to the library staff to become general in industry—perhaps more so if industrial research became organised, as Major Freeth suggests, by divisions of science instead of by divisions of practice.

The efficiency of the technical library for research purposes is, however, determined as much by the personality and enthusiasm of the librarian as by the mechanical perfection of its indexing system. His knowledge of the problems under investigation and their requirements, and his contact with the research staff, are the surest means of promoting contact and the resulting exchange of ideas and technique. The cramping or isolating tendency of the growing mass of recorded scientific information can only be countered by the play of intelligent individuality and enthusiasm.

A Century of Anatomy.

Quain's Elements of Anatomy. Eleventh edition. Editors: Sir Edward Sharpey-Schafer, Dr. Johnson Symington, and Dr. Thomas Hastie Bryce. In 4 volumes. Vol. 4, Part 3: *The Heart.* By Prof. Thomas Walmsley. Pp. vii + 152 + 2 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 16s. net.

THE brief historical introduction which Sir E. Sharpey-Schafer and Prof. Bryce contribute to Prof. Walmsley's monograph on the heart makes brave but gloomy reading.

Jones Quain published his "Anatomy" when he was a lecturer on anatomy in the Medical School, Aldersgate Street, in 1828. With the fifth edition, published twenty years later, the work passed into the hands of his brother, Richard Quain, and William Sharpey, professors respectively of anatomy and general anatomy and physiology in University College, London. Viner Ellis succeeded Richard Quain in the editorship, and was in turn succeeded by Allen Thomson and John Cleland, Sharpey continuing to contribute the general and microscopical anatomy, which had been the most striking change introduced when he first became associated with the work. Although enlarged, it still appeared in two volumes in 1876, when the present publishers issued the eighth edition, which, although contributed largely by Sharpey, Thomson, and Schafer, contained a chapter by Gowers on the brain and spinal cord. Also in two volumes was the ninth edition by Thane, Schafer, and Thomson, dedicated to Sharpey, who at his death had been responsible editor for thirty-five years.

The monographic form was assumed in 1890, when the eight parts of the famous tenth edition began to appear. Since then the only new authors until now have been Profs. Symington and Bryce Godlee assisting in the preparation of an appendix on superficial anatomy in the tenth edition. Sir E. Sharpey-Schafer has been editor for fifty-three years. The War and the death of Prof. Symington interrupted publication of the present (the eleventh) edition, which commenced with Prof. Bryce's volume on embryology in 1908. Monographs on neurology, splanchnology, osteology and arthrology, and myology have appeared, and one on angeology was in preparation by Prof. Bryce. "But the greatly increased cost of printing and engraving has, in the judgment of the publishers, rendered it necessary to postpone indefinitely the publication of this part. As the section upon the Heart . . . was ready for publication, it has been decided to make this the last portion of the edition." Although postponed indefinitely as a part of "Quain's Anatomy", Prof. Bryce's angeology may be published separately, and a volume on the lymphatic system by Prof. Blair will be. As the sole difference in the "cost of printing and engraving" would concern the titles of these works, it seems evident that for the time being publication of "Quain's Anatomy" now ceases in the middle of an edition the first parts of which are already urgently in need of revision.

There is nothing in the English literature of anatomy that will fill the gap. The work began a century ago as a students' handbook, and has developed along lines which, familiar enough on the Continent, are too little valued in England. Rather than a mere inventory of facts, it gave, and might have given increasingly, just that summary and discussion of ascertained knowledge that is necessary to serve as a link between it and the problems of the present. It has served the writers of text-books well on occasion, and a reference to its pages will continue to save many a practitioner from the hasty assertion that "there is nothing in the text-books about it". It is the only modern book on anatomy not written with an eye chiefly on examination papers. These surely are good qualities. In a generation in which medical practitioners look for inspiration to the empiricism of chemistry, therapeutical and metabolic, rather than

to morphology, it is intelligible that an anatomical work more compendious than the standard text-book will not find shelf-room in many studies; but it is to be regretted that the matter should end there.

The distinctive features of the parent work are well illustrated in Prof. Walmsley's contribution. The chapter on the comparative anatomy of the heart is discriminating. The heart is one of the most significant links between vertebrates and invertebrates, and as the heart of the latter has lately received much attention, this part of the subject might have received fuller treatment. The great problems are here. The reviewer agrees with Prof. Walmsley's view that a discussion of the comparative anatomy of the connecting systems of the heart is "perhaps as yet hardly profitable", but not altogether with the statement that the manner in which delay in conduction is produced is not primarily a structural problem. This is, however, not the place to discuss the intricacies of the considerable amount of work which has been done on the development of the conducting mechanisms. Prof. Walmsley recognises that the "whole question of the relation of nerve and muscle is involved" in the interpretation of the facts now known. His presentation of the matter, and indeed the whole section on the structure of the heart, is admirable.

Mathematical Genetics.

Variations- und Erblichkeitsstatistik. Von Prof. Felix Bernstein. (Handbuch der Vererbungswissenschaft, herausgegeben von E. Baur und M. Hartmann. Lieferung 8, Band 1.) Pp. iv + 96. (Berlin: Gebrüder Borntraeger, 1929.) 14·40 gold marks.

AS the sciences develop, they acquire an associated mathematics, and the young science of genetics is evolving a mathematical side at a rate which some of its exponents find disconcerting. Mathematical genetics falls primarily into two sections, which may be called synthetical and analytical. The former deals with the results to be expected on a given hypothesis, but in most cases the populations considered are infinite. The latter is essentially concerned with the theory of sampling, and the inferences which may legitimately be drawn from a given finite sample. Hence their problems are, in general, quite different.

On the synthetical side we meet with dynamical and statical problems. For example, we may wish to know what will be the effect on a population, the variation of which is due to a number of Mendelian genes, of a given type of inbreeding or selection. If generations are separate, we may be faced with anything from one to a series of 22 simultaneous finite difference equations, which may or may not be linear, connecting the values of variables in successive generations. An example of the non-linear type is $\Delta u_n = k f(u_n)$, where f is a known function. In this case u can be expanded as a power series in k. When successive generations overlap, as in man, the difference equations become integral equations. In their solution, functions of a complex variable appear for perhaps the first time in a purely biological problem. Often the dynamical problem is very intractable, but the population considered reaches an equilibrium which can be calculated. Such is the equilibrium between the production of new genes by mutation and their removal by natural selection, which, as Fisher showed, accounts quantitatively for Pearson's results on the inheritance of human stature, if this variation is due to the cumulative action of a large number of genes.

The analytical theory is, of course, very largely the work of Pearson and centres round the properties of the Gaussian error function and related functions. In the case where the population consists of a finite number of classes, his measure of divergence, χ^2, is an intellectual tool of extraordinary simplicity and value, as it enables the geneticist, with great rapidity, to answer two quite different questions. First, can my data, for example, records of a number of families, be regarded as samples of the same population, and therefore legitimately be grouped together? Secondly, with what degree of plausibility can these data be regarded as a sample of a population obeying a given law? A much more difficult type of problem arising from populations of the same type is that of the estimation of a parameter such as the cross-over value. Here there is no royal road to the solution. Bayes' theorem and Fisher's method of maximum likelihood are generally valuable, but cases occur where *ad hoc* methods are preferable.

Finally, we come to populations in which a character exhibits continuous or approximately continuous variation. Here the error function meets us both in the theory of the population itself and in that of samples of it. In spite of the very great labour devoted to this problem by Pearson and his school, we are still far from a really satisfactory mathematical organon, partly owing to

earson's reluctance to admit the application of endelism to such problems.

In the book before us Prof. Bernstein covers a ider ground than any previous author, and does in a remarkably short space. After two intro- ictory chapters on probability and statistical ieory, he describes the application of statistical ethods to data, with special reference to those ises where experiment is impossible, for example, ie inheritance of human disease. A good deal, iough by no means all, of the ground in this ction is covered in Fisher's "Statistical Methods r Research Workers", and the reviewer confesses a preference for Fisher's methods in many cases. early half the volume is devoted to Mendelian opulations, and is the only attempt so far made unite the more important work on this topic in ie book. No student of genetics who is concerned ith the wider bearings of his subject and has even slight knowledge of mathematics can afford to eglect reading it.

There are many defects in this book. For cample, it contains no tables, and a regrettable umber of errors. Thus, four papers by Robbins e attributed to Pearson. But it is the only book f its kind, and much may be forgiven to a pioneer. Ve venture to hope that in the near future Prof. ernstein, who is one of the three or four persons ualified to do so, will give us a full-length book on subject which is already beginning to have bear- igs on the theory of evolution, on hygiene, sychology, and politics.

J. B. S. H.

Huygens' Work in Statics and Dynamics.

Œuvres complètes de Christiaan Huygens. Publiées par la Société Hollandaise des Sciences. Tome 16: *Percussion, Question de l'existence et de la perceptibilité du mouvement absolu, Force centrifuge, Travaux divers de statique et de dynamique de 1659 à 1666.* Pp. iv + 500. (La Haye: Martinus Nijhoff, 1929.)

THE appearance of another volume of the superb edition of the complete works of Huygens, in ourse of publication by the Dutch Society of ciences, is an event to be welcomed unreservedly. lited with care and learning, it forms a most luable and interesting contribution to the history science in the seventeenth century.

The work here presented falls into three main visions: (1) impact, (2) centrifugal force, and) various researches on problems of statics and namics, dating from the period 1659–66. These last have been hitherto unpublished; and none of the work was published in the lifetime of Huygens himself. But each of the first two divisions contains a considerable memoir given to the world in the posthumous edition of 1703. These are entitled "De motu corporum ex percussione" and "De vi centrifuga" respectively.

Huygens observed the first rule for success in life by selecting his father most judiciously. It was under the paternal roof that he came in contact with the learned world, in particular with such men as Descartes, at an early age. But the glamour of Descartes' vivid personality receded as his own critical power developed, and so early as 1652 his researches led him to reject the French author's rules of impact and to supersede them by his own theory. On a visit to London in 1661, Huygens explained his method to some of the leading members of the Royal Society, but though the subject was of recurrent interest at the time, he published nothing beyond a few rules without demonstration in 1669. It appears that the reason for this reticence is to be found in a hope, never abandoned, that he would ultimately succeed in penetrating deeper into the true nature of percussion. It was not due to any dissatisfaction with the memoir prepared in 1656: and, in fact, his literary executors were explicitly instructed to publish this treatise.

It was otherwise with the memoir "De vi centrifuga", which was written in 1659 and published by Huygens' executors in 1703 on their own judgment. These two memoirs are now supplemented by a considerable amount of manuscript material, and linked by a series of notes left in a similar form and dealing with the question of absolute motion. In all this work there is conspicuous a sense of relativity, not of course in its modern meaning, but as a dynamical principle serving the purpose of research. In this respect Huygens made an important advance on the ideas of his predecessors. At first he was mainly concerned with the problem of rotation as a practical inventor, and it was only later that he considered it from a more metaphysical point of view. Adopting the attitude of an observer carried on a rotating disc and supporting a weight by a thread, he assimilated the centrifugal force to the force of gravity. The difficulty of reconciling this view with the Newtonian, which interprets the same phenomena from the point of view of the external, fixed observer, was strongly felt at the time and long after; the two aspects are practically united in d'Alembert's principle.

In any event, the work of Huygens must have exercised a profound influence on the development of dynamical theory, for in his work are to be found clear references to the principles of momentum and of energy. It cannot be an easy task to disentangle the achievement of Newton in this field from the debt which he owed to his contemporaries and predecessors. Perhaps his pre-eminence is to be seen in the generality and sufficiency which he divined in simple principles, and the intellectual confidence which was founded on sure insight, but appeared in a different light to others. The impression recorded by Huygens is instructive and may be quoted :

"Je m'estonne que Mr. Newton sur une hypothese si peu probable et si hardie, se soit donné la peine de bastir tant de Theoremes et comme une theorie entiere des actions des corps celestes. Je dis son hypothese qui est que toutes les petites particules des divers corps s'attirent mutuellement, et cela en raison double reciproque des distances. Il a pu estre conduit a sa theorie des orbites elliptiques par le livre de Borelli du mouvement des satellites de Jupiter, qui . . . n'a pas sceu penetrer les vrais fondements comme Newton qui a eu l'avantage de connoitre la mesure de la force centrifuge par les Theoremes que j'en ay donnèz" (p. 250).

Among the few notes by Huygens on statical problems is one on the breaking of a beam (1662), in which perhaps for the first time a moment is used in its modern sense as the simple product of a force and a distance, a concise notion which only recurs in the work of Varignon in 1687. The dynamical notes refer chiefly to two problems, the tautochronous property of the cycloid and the length of the simple equivalent pendulum for bodies of different shape. On the first of these subjects a complete series of notes makes it possible to trace the idea from the germ to the form finally developed in the "Horologium oscillatorium" in quite unusual detail. Huygens' interest in the second subject was aroused by Mersenne (vir—according to Huygens père—omnigenae sed indigestae eruditionis), who had arrived at the identity of the centres of oscillation and percussion, apparently as the result of experiment. Huygens calculated the position of the centre of oscillation in a number of cases, and reached a certain limited degree of generality by his methods of integration. The term 'moment of inertia' was only introduced later by Euler (1765), to whom we also owe the convenient symbol Σ (1755).

As the work of Newton is marked by a bold and penetrating generality, so the work of Huygens has its own quality apart from the particular results achieved. This appears in a greater attention to exact definition and an appreciation of the value of precise formulæ, leading to a more concise form of statement than that generally attained to by his predecessors. To quote two of his aphorisms from this volume :

Nisi principium ponatur nihil demonstrari potest.
Non est mathematicœ difficilis materia, sed physicœ aut hyperphysicœ (metaphysicœ).

Hence, as the present editors remark, to Huygens may be traced a distinct influence on the development of mathematical style in the following century. But it was a slow growth, as various passages in the works of Euler may serve to suggest, and it was reserved to the French mathematicians, Lagrange in particular, to set such a standard as can scarcely be surpassed. H. C. P.

Primitive Art.

The Childhood of Art, or The Ascent of Man: a Sketch of the Vicissitudes of his Upward Struggle based chiefly on the Relics of his Artistic Work in Prehistoric Times. By Herbert Green Spearing. Second and revised edition. Vol. 1. Pp. xxxvi + 254 + 62 plates. Vol. 2. Pp. iv + 255-548 + 56 plates. (London: Ernest Benn, Ltd., 1930.) 42*s*. net.

THE first edition of this book was published so long ago as 1912. It was then rightly acclaimed as a book which no student of early art could afford to be without. It gave a balanced sketch of primitive art as then known with a wealth of illustration. It was up-to-date and truly 'the last word on the subject'.

From 1912 to 1930 is, however, a gap of eighteen years. In the preface to the new edition the author admits that "since 1912 . . . there have been notable archæological discoveries in many parts of the world"; but he adds that "most of them . . . have only added picturesque details to the connected story". I fancy by no means everyone will agree with the author in this statement. Surely the new finds at Ur and the Copper Age art of Spain—to give but two examples—have both enriched and complicated the story: they should certainly have been allotted their due space in a revised edition. Even such a discovery as that of the 'sorcerer' at the Trois Frères cave enlarges our ideas of prehistoric man and is therefore important in a study such as this, which professes to deal

with the ascent of man, traced mainly by studying his artistic achievements. These two volumes are really only a reprint of the original work with the addition of a short preface and the names of a few recent books in the bibliography. It was careless, however, to give Sollas's "Ancient Hunters" as published in 1911 instead of citing the third edition issued in 1924!

It is difficult to understand why the second edition of this work should not have been very largely rewritten. When a second edition of a book is called for soon after its first publication, or when the subject matter is purely an account of observed facts, such as a monograph on some excavation, it is reasonable to reissue what is in reality the same work with the same outlook on the subject. But in the case in question, not only have many recent startling discoveries been made, but many of the problems interesting in 1912 now strike the reader as rather out-of-date. Why quote at length Piette's dogma that sculpture must have preceded line engraving? The fact may have a grain of truth in it (though such Aurignacian line engravings as those found at the abri Labatut have to be taken into account), but Piette, though, in his own time, a pioneer, can no longer be considered as the great authority. He never realised the existence of the Aurignacian culture, and still less did he appreciate that the late Palæolithic art cannot be taken as a single entity, but forms two distinct cycles, one Aurignacian, the other Magdalenian, the evolution of each of which has to be treated separately. What Sumerian authorities will think of the paragraphs dealing with the Sumerians and their art will scarcely be complimentary. Wooley's name does not appear; it is relegated to a few notes in the preface; nor is such a find as the queen's diadem mentioned.

To sum up, the "Childhood of Art" was a good, well-balanced book in 1912. The revised edition is really only a reprint where even the page numbering is the same, and where the only striking differences in the main text are that several plates formerly coloured are now reproduced in black and white; that the table facing page 5 is much abridged; and that the final map is on a far smaller scale than before. Of course there is much that was interesting in 1912 that remains so in 1930, but in the case of a rapidly advancing subject it might have been kinder to have let the author rest on his well-earned laurels without bringing him once again into the arena armed only with the ancient panoply of war.

Our Bookshelf.

The Flutter of Aeroplane Wings. By R. A. Frazer and W. J. Duncan. (London: H.M. Stationery Office, 1929.) 12*s.* 6*d.* net.

A CRITICAL examination of the causes of a large number of aeroplane accidents, undertaken by the Accidents Investigation Sub-Committee of the Aeronautical Research Committee, has brought out the fact that in many of them a rapid and unusually large movement or flutter of the wings had been apparent. The sub-committee immediately undertook a thorough investigation of the vibration of aeroplane structures, both from the theoretical and experimental point of view, to provide data from which designers could ensure the avoidance of this instability. The work has been undertaken mainly by Messrs. R. A. Frazer and W. J. Duncan at the National Physical Laboratory, and their provisional conclusions and practical recommendations are published in this monograph.

The theoretical part of the volume deals with the equations of motion of the wing-aileron system, with stability criteria, and critical flutter speeds, and with a graphical treatment of binary flutter problems, involving only two degrees of freedom. In the experimental investigation the authors had to develop a special technique for the measurement of the derivatives on flexible wings, due to torsion and flexure of the wing itself, and to aileron movement. The agreement between the observed and calculated critical speeds was sufficiently good to warrant the conclusion that the theory is adequate for the discussion of aeroplane wing flutter; but its real value lies in the methods it suggests for preventing flutter.

The third part of the monograph deals with various recommendations for prevention of each special type of flutter. Cantilever monoplanes, stayed monoplanes and biplanes are separately discussed, and the influences of elastic hysteresis, of friction, and of abnormal wing incidences are thoroughly dealt with.

The monograph has a number of appendices dealing with specialised matters, contains an annotated list of references, and a list of the principal symbols used with their significance. An adequate index for the whole volume is included. It is an excellent record of a very valuable series of investigations.

Ultra-violet Light and Vitamin D in Nutrition. By Katharine Blunt and Ruth Cowan. (The University of Chicago Home Economics Series.) Pp. xiii + 229. (Chicago: University of Chicago Press; London: Cambridge University Press, 1930.) 11*s.* 6*d.* net.

RECENT work on vitamin D and nutrition has been so extensive and so important in practical application that the appearance of an up-to-date monograph on this subject is most welcome. This book provides a convenient account of widely scattered researches, and also includes judicious summaries

of such practical conclusions as are justified in the present state of knowledge.

The first chapter describes some studies on the effect of diet on growth, which are at least encouraging, and confirm the opinion that civilised nations need not deteriorate in physique in spite of urban life. There follows a brief historical chapter, and then an account of the methods of producing and studying experimental rickets in rats in order to detect or estimate vitamin D. This chapter would perhaps be improved by including a fuller account of the radiographic study of rickets in rats, since this method has appreciable advantages over the line test when used for quantitative estimations. There follow chapters on the complex problems of calcium and phosphorus metabolism, on teeth and vitamin D, and on irradiated foods and ergosterol. There is also a section describing some of the physical aspects of ultra-violet radiation, with a well-balanced summary of the advantages and limitations of ultra-violet transmitting glasses intended for the windows of buildings. A further section on the results of actinotherapy is less satisfactory, possibly because of the great difficulty of justly appraising these results at the present time. Each chapter concludes with a bibliography of the more important papers concerned, which adds greatly to its value.

The book can be recommended not only to medical men and others interested in nutrition, but also to research workers who may need a summary of branches of work allied to their own special subjects.

R. B. B.

(1) *Air Defence.* By Major-Gen. E. B. Ashmore. Pp. viii + 179. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 8*s*. 6*d*. net.

(2) *La folie et la guerre de 1914–1918.* Par A. Rodiet et Prof. A. Fribourg-Blanc. Pp. iii + 194 + 10 planches. (Paris: Félix Alcan, 1930.) 30 francs.

THESE two books may be included in one notice, for they both deal with the War, though from entirely different points of view. General Ashmore, who was placed in command of the London Air Defences in 1917, succeeded in organising a very telling defence, following upon the previous feeble results recorded against German raids, particularly as regards aeroplanes. He develops his subject herein as lucidly as he developed the defences, and higher praise it is impossible to bestow. His concluding remark is worthy of note: "If we maintain an efficient air defence, we may never be attacked".

The other book details the effect of the War in producing or intensifying mental alienation in French subjects, and deals with 220 cases out of a total approximating 25,000. Investigation suggested that the syndrome known as shell-shock was not to be regarded as a special form of mental disease, but merely as the determining factor in a general condition of mental obliquity. Further, it is remarked that psychoses associated with, or succeeding, infectious diseases would doubtless have been very numerous, had it not been for the prophylactic measures taken at the commencement of the War. There are intensely interesting notes upon malingering, and altogether this is a very valuable compilation.

P. L. M.

Diet and Efficiency: a Five-year Controlled Experiment on Man. By Harold H. G. Holck. (The University of Chicago Monographs in Medicine.) Pp. ix + 72. (Chicago: University of Chicago Press; London: Cambridge University Press, 1929.) 4*s*. 6*d*. net.

THE purpose of this experiment carried out on a single individual was to determine the effect upon mental and physical processes of a fairly strict adherence to the principles of nutrition laid down by Fletcher. These principles may be stated thus: (1) Eat only when actually hungry; (2) stop when satisfied; (3) chew the food especially well; (4) if available try to secure any food for which there seems to be a craving and omit those to which there may be antagonism. Of the five years of the experiment, only about 18 months were taken up by the experiment proper, the remainder being pre- and post-periods. Very full records were kept throughout.

The results may be stated quite briefly: the eating time per 1000 cal. was doubled and the food intake was at a minimum, although its percentage composition of protein, fat, and carbohydrate was almost unchanged, as compared with the control periods. Muscular endurance, typewriting accuracy, and basal metabolism were reduced, but there was no change in blood-pressure, pulse-rate, temperature, sleeping time, mental multiplication, and typewriting speed: efficiency in solving chess problems was improved. The body weight was reduced to the accepted standard for the subject's height and age. The general conclusion appears to be that reduction in food intake in a somewhat overweight subject does not always lead to improvement in mental and physical well-being, and that the minimum intake compatible with maintenance of weight at an accepted 'standard' level may not be the optimum in all cases.

Alpine Flowers: the Most Common Alpine Plants of Switzerland, Austria, and Bavaria. By Dr. Gustav Hegi. Authorised translation by Winifred M. Deans. Pp. xiii + 74 + 38 plates. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1930.) 7*s*. 6*d*. net.

MISS DEANS has prepared an excellent translation of Dr. Hegi's handy little book, "Alpenflora", which should be very useful to visitors to the Alps who may wish to identify the flowers they come across in their rambles on the mountains. All the plants described are illustrated, and the coloured plates are, on the whole, quite good, and allow the plants to be determined with ease. The botanist may be somewhat disappointed, since so many of the plants he would come across are not referred to in the book, but for him the larger works on the Alpine flora are available. The general flower-loving public should welcome the book.

Letters to the Editor.

Space and Matter.

REFERRING to NATURE of June 14 and to the teresting résumé on page 897 of Prof. Einstein's 'ottingham lecture, I note that he virtually agrees ith me in claiming matter as passive and space as tive. Matter is that which is acted upon; space is at which acts. Matter is inert; space is energetic. atter *does* nothing, though it serves to display the ergy of which space is full: it merely sails placidly ng the path of least resistance, like a straw in a ream or a leaf in the wind.

It used to be thought that potential or static ergy existed in the ether, while locomotive energy as possessed by matter; but we now know that omentum is electromagnetic, and accordingly exists the space around the unit of matter which displays . So, strictly speaking, all energy belongs to space. atter only affords a means of detecting and using it.

There is no objection to an inert thing being able o receive and transmit energy; and yet when we say hat matter is a form of energy, equal to mc^2, it is lear from the occurrence of c that space must really e responsible for the energy. So also for the increase f energy due to motion, which is responsible for the ind of relative kinetic energy familiar to engineers; is involved in that too. For $\frac{1}{2}mv^2 = c^2dm$. As for he irregular or statistical energy that we call heat and sually consider material, the heat motion of particles partly visible in the Brownian movement, which as emperature rises must grow in intensity. Whatever true about the locomotion of particles is true also f this irregular motion.

We know that the mass of an electron is accounted or by the energy of its electrostatic field. So matter, trictly speaking, has no active properties at all. When we say that matter is a form of energy, we mean hat its existence is the sign or symbol of certain inds of energy in space, and affords a possible means f getting at it. (It would be pedantic and inconvenient to be perpetually remembering this, so we ay still attribute momentum and kinetic energy and eat energy to matter.)

This applies to all matter. There is no discrimination between the so-called animated variety and any ther. Hence the task of the biologist or the behaviourist to explain vital activity in terms of matter must be futile. Every part of every body must be ontrolled, guided, activated, by something in space. When an organism interferes with, or in, the course of Nature, it does so because it is actuated by something utside itself; something familiar in its effects, and sually called Life, but not yet discovered or formulated in proper terms.

Although matter has no energy and never does nything, yet it is to us the conspicuous thing, because r nerves, which are themselves material, respond the perturbations of space; thereby stimulating ur sense-organs, and giving us information about hose perturbations. Matter is one of the perturbations, but it is entirely inert. Space is the primary and active thing.

Space with physical properties is usually called ether; but what those properties in themselves are, is the problem before us—a problem which must have deep-seated philosophical consequences. OLIVER LODGE.

Normanton House, Lake, Salisbury, June 20.

Absorption of Sound at Oblique Incidence.

IN the U.S. Bureau of Standards' *Journal of Research* for February 1930, pp. 289-296, there appears a description of apparatus employed by P. R. Heyl, V. L. Chrisler, and W. F. Snyder, for the investigation of the absorption of sound at oblique incidence. A plate of the material to be tested was placed at a flat elbow joining two cylindrical pipes in the way shown diagrammatically in the accompanying sketch (Fig. 1). The results obtained were compared with certain calculations made by me relating to the reflection of plane waves of sound from a flat surface.

The theory underlying the method appears to be that plane waves travelling down the pipe A will be reflected from the plate of material under test and will pass into B in accordance with the laws of rectilinear propagation as commonly employed in optics when the dimensions of the reflecting surface are large compared with the wave-length. In the experiments at the Bureau of Standards, however, the diameter of the pipes which convey the sound to and from the test plate was only a fraction of the wave-

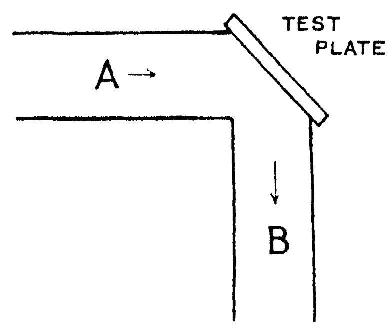

FIG. 1.

length of the sound employed, and an assumption of rectilinear propagation at the elbow seems scarcely to be justified. Part of the energy of a plane wave travelling along A will pass into B by diffraction, and also any sound reflected from the test plate will spread partly into A and partly into B. For these reasons I am inclined to think that very little value can be attached to the coefficients of absorption at oblique incidence which are given in the paper referred to. At any rate, they are certainly not the coefficients for plane waves at oblique incidence.

One of the substances tested at the Bureau of Standards was 'akoustolith', an acoustic tile similar to certain acoustic plasters concerning which I have made theoretical deductions leading to the conclusion that the coefficient of absorption for plane waves at oblique incidence would, except near grazing incidence, be greater than at normal incidence (*Proc. Roy. Soc.*, A, **115**, pp. 417-419; 1927). Heyl, Chrisler, and Snyder found with their apparatus that the absorption of akoustolith (at 512 and 1024 cycle/sec.) was less at 45° and 60° than at normal incidence, and less at 45° than at 60°. To explain the discrepancy between their observations and the theoretical conclusions, they invoke the aid of "a thin layer of air close to the absorbing surface" where the "differential equation for sound motion in air is not valid" (loc. cit., p. 290). In this layer they imagine there is a rotational motion of the air particles, and conclude that "it is unsafe to apply to such a region mathematical analysis involving the assumption of the existence of a velocity potential. Theoretical conclusions based on such reasoning are invalid" (p. 295). There appears to be no evidence that this layer exists (or that, even if it exists, it exerts any perceptible effect on sound absorption) apart from the discrepancy referred to

above, and this could equally well be explained by the falsity of the assumption that the observed coefficients are those for plane waves at oblique incidence.

In the theory which I have attempted to develop of the absorption of sound at oblique incidence by substances such as akoustolith, it is assumed that air is forced into and out of the pores by the pressure variations at the reflecting surface, and that this in-and-out motion is accompanied by the degradation of sound energy into heat. I believe that this degradation takes place inside the pores and is due to the working of viscous forces, but it may be remarked that this view is not shared by Heyl, Chrisler, and Snyder, who think that there may be degradation due to viscous forces just outside the reflecting surface. Thus they say (p. 290) that "even with glass which has no sensible pores, there is an appreciable amount of absorption of sound which must arise from friction of some kind, probably of a sliding nature". It would be interesting to know the reason for supposing that the absorption (that is, loss at reflection) must necessarily be due to friction. The fact is that there is a loss of energy at reflection amounting to some 2 or 3 per cent, and I suggest that this could be accounted for by the transmission of sound into and through the glass test plate.

In the theory of sound absorption at oblique incidence it is assumed that the mass-flow of air into the pores (dm/dt) per unit area of reflecting surface is connected with the pressure variation (p) at the reflecting surface by the equation $dm/dt = \Omega p$, where Ω is a complex quantity (the acoustical admittance per unit area) which is constant for a given surface and wave-length of sound. The incident and reflected waves were, for convenience, represented by velocity potentials, but the motions inside the pores were not taken into consideration. The quantity Ω can be measured with the usual type of stationary wave apparatus, and the absorption at any angle of incidence could then be calculated by means of a formula given in the paper quoted above. The mechanism by which the loss of energy from the incident wave occurs (apart from the fact that it is associated with the motion of the air into and out of the pores) need not be known.

The late Lord Rayleigh, in his paper on "The Resonant Reflexion of Sound from a Perforated Wall" ("Sci. Papers", **6**, p. 662), used potentials to represent the incident and reflected waves and also the wave transmitted into the pores, this last potential being chosen so as to represent the dissipation of energy by viscosity in the pores. I see no objection to such a treatment, and there seems to be no reason for doubting the general truth of the formulæ which he obtained for the reflection of sound waves at oblique incidence.

In their "Discussion of Results", Heyl, Chrisler, and Snyder advance theoretical reasons (p. 294) for supposing that the coefficient of absorption will "diminish steadily with increasing obliquity of incidence". They begin with a statement that "a sound wave is not a convection current". No one is likely to quarrel with this premise, but I have been quite unable to follow their subsequent line of thought. It is considered that the amount of absorption is closely connected with the 'average pressure' over the reflecting surface. Except for the second order 'radiation pressure', I should have thought that the average pressure over a reflecting surface would be atmospheric pressure no matter what might be the angle of incidence. Certainly this would be so in the case of plane progressive waves reflected from a flat surface.

The interest attaching to the determination of the coefficient of absorption for plane waves at oblique incidence is partly due to the fact that if the coefficient for some material were known for all angles of incidence, an experimental test could be made of the theory of reverberation. In this theory, which was developed by W. C. Sabine to account for his experimentally established laws of reverberation, rectilinear propagation of sound is assumed, and, if the theory is true, it is possible to calculate the coefficient of sound absorption, as it would be measured in a reverberation experiment, from the values of the coefficient at oblique incidence. The method of calculation is given in *Phil. Mag.*, **5**, pp. 489-497; 1928. The theory that absorption increases with angle of incidence does at least offer an explanation, on the basis of reverberation theory, of why the reverberation coefficients of acoustic plasters, etc., are found to be greater than their coefficients at normal incidence. I cannot see any reason why, if, as Heyl, Chrisler, and Snyder suppose, the absorption decreases with angle of incidence, the absorption in reverberation should be greater than when the waves are incident normally. I should have expected exactly the opposite.

One of the conclusions reached at the Bureau of Standards is that "in the practical measurement of absorption coefficients the reverberation method should be the only one trusted for absolute values of the coefficient". It would be of interest to know what is meant by the 'absolute' value of the coefficient and how it differs from any other value. The method adopted must surely depend on the quantity it is desired to measure. Coefficients at normal incidence can best be determined with stationary wave apparatus, while reverberation coefficients are at present most suitably found by reverberation experiments. It is, however, at least possible, and even probable, that reverberation coefficients could be calculated from observations made with stationary wave apparatus.

Origin of Asymmetry in Gastropods.

IN his review of Dr. de Beer's "Embryology and Evolution" (June 14, p. 883), Prof. MacBride appeals to readers of NATURE to decide between two theories of the origin of asymmetry in Gastropods. He supports the opinion that the weight of the shell stretched one side of the animal and crushed the other, thus initiating an inequality of growth. On the alternative view "a sudden and miraculous mutation" twisted the visceral hump and shell through 180°.

Now the first theory postulates the transmission to the offspring of the effects of injury, to wit, stretching and crushing. Whatever may be the case with other acquired characters, attempts to prove the inheritance of the effects of mechanical injury have been conspicuously unsuccessful. On the other hand, "miraculous mutations" resulting in asymmetry of symmetrical animals have been reported. Thus Bridges and Morgan [1] describe a mutant form of *Drosophila melanogaster* in which the abdomen is rotated to the left through 60° to 90°. This type has a poor viability, and cannot mate, hence the mutation is disadvantageous to *Drosophila*. If it were advantageous it would be perpetuated by natural selection.

While I see no reason to adopt either of these theories, which are not mutually exclusive, as to an event which took place in pre-Cambrian times, I find

ie second more attractive because, unlike the first, is based on analogy with facts which have actually een observed.

J. B. S. HALDANE.

John Innes Horticultural Institution,
Merton Park, London, S.W.19,
June 17.

Bridges and Morgan: *Carnegie Inst. Pub.* 327.

IN the above letter, Mr. Haldane misinterprets the ieory of the origin of Gastropoda as a consequence f the sagging of the visceral hump to one side. The igging of the visceral hump no more 'injured' the ncestral mollusc than does the weight of her pro- iberant abdomen a pregnant woman. It con- nually stimulated the skin of one side by stretching and what was transmitted to posterity was not ie passive stretching but the altered *habit of growth* illed forth in response to it. That such altered habits f growth do become hereditary has been proved by very relevant experiment on the subject. As I have iid elsewhere, Przibram enumerated at least six xamples of this. I have just returned from a northern niversity where pioneering genetical research is going n. I think it probable that in the near future 'rzibram's six examples will become at least ten.

Mr. Haldane instances a *Drosophila* with distorted bdomen as giving an example of the sudden miracu- ous mutation which De Beer postulated as the origin f the Gastropoda. He admits that this individual 'as so enfeebled that it would not mate, much less ive rise to offspring. He overlooks the fact that the 'ant of viability of the mutants of *Drosophila* is 1 direct proportion to their divergence from the ype; and the idea that an enfeebled mutant would e preserved by 'natural selection' when all its ormal bilaterally symmetrical fellows perished is one hat cannot be entertained. No competent systema- ist, palæontologist, or embryologist would agree with Ir. Haldane, and it is these people who have the final rord on the causes and course of evolution.

The Position of Fundamental Research.

IN the interesting leading article in NATURE of Iay 31, a lament is sounded that pure research of the ind fostered in colleges and universities is no longer ble to attract the best of the younger scientific tudents. The cause is attributed to the relatively oor salaries which colleges can offer: and this opinion substantiated by comparison between the financial ewards of commerce and industry on one hand, and f the teaching and research profession on the other.

Although lack of money may be a powerful con- ributory reason, it would seem that the real cause of he shortage lies deeper. Surely pure research is done est by persons who are inspired in their work, and apported best by institutions to whom their work is iseful.

The universities fostered research because teachers ould not, in general, remain in the forefront of their espective fields unless they were creating as well as tailing knowledge. It was recognised that research vas necessary to inspire teaching; and later the nteresting belief became common that teaching, with ts continual summarising of existing knowledge, its egular routine, and the stimulus of irksome duties nd of question and of answer, was equally necessary o fertilise research. That was when the preponder- ance of scientific knowledge was situated within the university campus.

At the present time much of scientific learning is housed within the walls of industry, and it is to industry that even your pure scientist looks for the greatest inspiration. Industry in America has known for years that works laboratories stocked with tech- nicians, inventors, and trouble tracers soon become sterile unless pure research, with its right to publish and its consequent prestige to the individual, is care- fully fostered. This does not mean necessarily that a few privileged persons are permitted to pioneer scientifically in a building where others are kept strictly to the kind of work bearing immediate profit. It means often that those who have the mental equip- ment use part of their time on industrial problems, part in pursuit of their scientific hobby—pure re- search. One has only to cite Langmuir's work on adsorption, Sheppard's discoveries in photographic sensitivity, or the scientific publications of the Bell Telephone Laboratories, to see how amazingly industry has stimulated scientific minds in the pursuit of knowledge for its own sake.

The old academic feeling that there was something vaguely discreditable in a discovery which could be put to practical use is passing. Those who love know- ledge for its own sake now often have the double satis- faction of securing an advance of understanding, and at the same time seeing this advance aiding the manu- facture of some product in enormous quantities.

The tragedy, one feels, is not that the colleges can no longer attract young men for research, but that they cannot provide the whole environment of research, leisure, and remuneration which is necessary to secure the best men to train those other keen young scientists who will later find their opportunity in the industrial research laboratories.

Triatomic Hydrogen.

IN recent years various observers have investigated the formation of active hydrogen in discharge tubes at pressures ranging from two centimetres to atmo- spheric. The evidence has been both positive and negative.

In the formation of atomic hydrogen by R. W. Wood's method, it is considered that the water vapour poisons the glass walls and prevents the reversion to molecular hydrogen. Lewis (*Jour. Am. Chem. Soc.*, **51**, 654; 1929), in a study of the influence of surface upon the after glow in nitrogen, found that water vapour or paraffin poisoned the walls of the glass bulb to such an extent that the life period of the glow was doubled or tripled.

A study has been made of the influence of surface upon the formation of triatomic hydrogen based upon Wood's theory. We have repeated the work of Urey and Smallwood (*Jour. Am. Chem. Soc.*, **50**, 620; 1928) dealing with corona and vacuum tube discharges. We find that their results are correct under their experi- mental conditions. No appreciable activation of hydrogen is observed. However, when we introduced a trace of oxygen before the gas mixture reached the discharge tube, the results were positive as shown by the lead sulphide formed on the lead acetate paper.

To test Wood's theory still further, we poisoned the walls of the discharge tube with stearic acid and omitted the oxygen from the stream of pure hydrogen. The results were again positive, showing that hydrogen is activated in discharge tubes above 2 cm. pressure. During the latter part of this work, fresh plastic

sulphur was used in place of flowers of sulphur. The flowers of sulphur were treated to remove volatile sulphides. A large number of blanks were run wherever there was any doubt existing about results being influenced by sulphur blown back into the discharge tube. We found tubes easily contaminated until we used plastic sulphur.

During the course of this work a paper by Wartenberg and Shultz was published (*Zeit. Physik. Chem.*, **6**, 261; 1930) showing that orthophosphoric or metaphosphoric acid may be used successfully to poison the walls of a Wood's discharge tube in the production of atomic hydrogen.

Our experimental evidence further supports R. W. Wood's theory, and offers an explanation of the discrepancies existing regarding the production of triatomic hydrogen in discharge tubes.

We can duplicate the work of Urey and Smallwood if we remove the oxygen from the gas stream. If we introduce a trace of oxygen we check the results of Wendt and Landauer (*Jour. Am. Chem. Soc.*, **42**, 930; 1920. *Ibid.*, **44**, 510; 1922).

We wish to express our appreciation to the Canadian National Research Council for aid during the course of this work.

Pleochroism and Crystal Structure.

IN a very important paper (*Phil. Mag.*, vol. 33, p. 521; 1917), Silberstein developed a theory of molecular refractivity based on the idea that the electric doublets induced by the field of the light wave in the atoms composing the molecule influence each other, the result of such atomic interaction largely depending on their relative distances and the geometric form of the molecule. One important consequence of Silberstein's theory, namely, that gaseous molecules should in general be optically anisotropic, is supported by observation, and has been worked out in detail by Ramanathan, Havelock, and others; it also forms the basis of W. L. Bragg's well-known and successful attempt to compute theoretically the birefringence of the solid carbonates and nitrates from their known crystal structure.

In the present note we desire to direct attention to another important consequence of Silberstein's theory, namely, that atomic interaction induces pleochroism in ions or molecules: such pleochroism would become accessible to observation when they are regularly oriented as in a crystal. In a recent paper (*Ind. Jour. Phys.*, vol. 4, p. 1; 1929), Sir C. V. Raman and S. Bhagavantam have indeed suggested that the colour and pleochroism of solid organic compounds arise in this way. We have made some observations on the absorption of *polarised ultraviolet light* in crystals of sodium and potassium nitrates which appear to be very significant in this connexion.

It is known from the X-ray evidence that the NO_3 ions form a plane structure normal to the trigonal axis in sodium nitrate and to the pseudo-hexagonal axis (' c ' axis) in potassium nitrate. We have found that the selective absorption at about 3000 A. which appears in aqueous solutions of the nitrates manifests itself in the solid crystals only when the vibrations are in the plane of the NO_3 ions; vibrations of this frequency perpendicular to the plane of the NO_3 ions are freely transmitted by the crystals. Further, beyond about 2600 A. begins another region of strong absorption in the crystals which is also polarised in the same direction as the 3000 A. band. It is also found that while the refractive index of the ordinary ray shows a rapid increase even in the visible region with diminishing wave-length, the corresponding increase in that of the extraordinary ray is much slower. These observations taken together with W. L. Bragg's work on the birefringence of the nitrates appear to indicate that the basic ideas of Silberstein's theory are substantially valid.

Sense of Smell of Longicorn Beetles.

IN the notice of Ivar Trägårdh's paper on the pine-sawyer pest in Sweden, which appeared in NATURE of April 5, page 546, doubt is expressed that longicorn beetles are attracted by means of their sense of smell "to trees in the condition they require for oviposition". The writer of the notice cites an opinion held some twenty years ago that the Indian sal heartwood borer, *Hoplocerambyx spinicornis*, discovers newly felled trees by an unerring 'instinct' ("Indian Forest Insects", p. 323).

Recent field-work on the biology of *Hoplocerambyx* supports the contention of Tragardh, for the beetles (of both sexes) react immediately to the smell of a newly felled *Shorea robusta*, and in particular to that of the sap freshly liberated by the act of felling. If beetles happen to be near at hand, they discover the tree in the course of a few minutes. By cutting isolated sal trees in open country, it is possible to attract beetles in less than an hour from forest at a distance of at least half a mile. I have observed that the beetles approach upwind, flying low, and in a remarkably straight course towards their objective; with an appreciable breeze no beetles appeared from the forest to the windward. Arrived at the tree they drink the sap. As this species is on the wing during the monsoon season, they are not attracted to the tree for the sake of water only.

In the course of a day or two the attraction of the felled tree diminishes considerably and the beetles disperse; but by logging the tree or by stripping off the bark, or by otherwise exposing fresher sap, the attractiveness of the tree can be renewed for a further short period, and new beetles appear.

This principle has been used in the control operations against the sal heartwood borer during the recent serious epidemic in Central India; by means of trap-trees felled at appropriate periods and inspected systematically, millions of beetles have been collected and destroyed.

Kekule and Kolbe.

I WRITE Kekule without an accent, as he was a descendant of old Bohemian nobles, the Kekule de Stradonice, whose ancestors, being Bohemian brothers, had to emigrate after the battle of the White Mountain (1620); it is he whom we thank for the reform of organic chemistry. As a man of Slavonic origin Kekule was a 'romanticist' and arrived at his doctrine of the chemical structure more by genial intuition than by experimental investigation (see Brauner: "Collection" II., 225). On the other hand, I agree with my old friend, Prof. Armstrong, who said in his excellent review (NATURE, May 31, 1930, pp. 807-810) that the rôle played by Kolbe in our science is often

sufficiently appreciated. This is probably due to the circumstance that not all teachers of chemistry stick to the principle that special lectures on the evolution of chemical theories ought to be given to advanced students, as I did for many years. Kolbe as the type of a 'classicist' of German origin. His work was done under the influence of his great teacher, Bunsen, another 'classicist'. I wish only to direct attention to the constitution of carbonic acid, $C_2O_2{}^{OHO}_{OHO}$, and its derivatives, which, though written in Gmelin's equivalents, was, according to my modest opinion, the first correct structural formula and in which the carbon atom C_2, translated into our modern views, appears as *tetravalent*. For the same reason it follows his formula of sulphuric acid, $S_2O_4{}^{OHO}_{OHO}$, that is a structural formula containing *hexavalent* sulphur. Both geniuses retain their value.

Flint Implements of Lower Palæolithic Age from Yorkshire.

IN NATURE of June 7 appears a letter from Mr. J. P. T. Burchell stating that Mr. Dewey and myself have made an official examination for the Geological Survey of the sites in Yorkshire from which Mr. Burchell has obtained implements. His letter gives the impression that we are substantially in agreement with him on the claims made in NATURE of Feb. 15, where the implements are said to be from "the base of the Uppermost Boulder Clay of the area"; whereas Mr. Burchell is fully aware that both Mr. Dewey and I deny that the deposit is a Boulder Clay.

As several Yorkshire geologists have expressed their surprise at the views which Mr. Burchell's letter has led them to attribute to me, I wish to state that in my opinion the deposit containing worked flints, though it may belong to the latest stage of the Pleistocene, is of much later date than the latest Boulder Clay. Reasons for this opinion will be given in the detailed report shortly to be issued. I am content, as a geologist, to leave the cultural stage of the flints to be settled by the archæologists; if there should be general agreement that they are Palæolithic I can accept the overlying deposit as latest Pleistocene; but I am equally ready to accept it as Recent or Holocene, if the flints are Neolithic or later. I also consider that the flake mentioned in the last paragraph of Mr. Burchell's letter as having been found at Burstwick in my company may "from its stratigraphical position" be much "later in date than the early Mousterian period".

Spectrum of Inert Gases in their Second Stage of Ionisation.

ARGON, krypton, and xenon when they are excited to their second stage of ionisation give rise to spectra which should theoretically come under quintet and triplet systems. The position of different transitions can without difficulty be predicted with the help of the 'irregular doublet' law and the 'horizontal comparison' law (*Ind. J. Phy.*, vol. 3, part 1; 1928). Thus, with the knowledge of the nature and the position of the spectra we could identify certain lines and finally classified lines arising from the transitions below:

$$\begin{array}{ccc} & M_3 & \\ & \uparrow & \\ N_1 \leftarrow & N_2 & \leftarrow N_3 \\ & \uparrow & \\ & O_1 & \end{array} \qquad\qquad \begin{array}{ccc} O_2 & & \\ & & \\ P_1' \leftarrow & P_2 & \leftarrow \\ & \uparrow & \\ & Q_1 & \end{array}$$

Argon. Xenon.

The following chart shows the details:

	Argon.	Xenon	
$X_3{}^5D_4 \leftarrow Y_2{}^5P_3$	29964·5	25479·8	where X, Y, Z
$Y_1{}^5S_2 \leftarrow Y_2{}^5P_3$	30424·2	26437·5	correspond to
$Y_2{}^5P_3 \leftarrow Z_1{}^5S_2$	33058·3	34393·1	M, N, O for
$Y_2{}^5P_3 \leftarrow Y_3{}^5D_4$	41248·4	36788·0	argon, and
diff. ${}^5P_2 - {}^5P_1$	86	291	O, P, Q for
„ ${}^5P_3 - {}^5P_2$	148	415	xenon.

For krypton, Prof. Acharya identified the line 30800·0 as ${}^5S_2 - {}^5P_3$ due to the transition $(O_1 \leftarrow O_2)$, (NATURE, Feb. 16, 1929); but from the consideration of the differences $P_2 - P_1$ and $P_3 - P_2$, as well as from the intensity, we see that the probability of the line 30858·8 is greater for the transition than that previously identified by Mr. Acharya. The differences $P_2 - P_1$ and $P_3 - P_2$ are 162 and 273 respectively.

Band Systems Associated with Selenium.

A LARGE number of heads in the band spectrum attributed to selenium have been carefully measured by Messerschmitt.[1] A number of these can be identified with heads in the absorption and fluorescence spectra analysed by Rosen.[2] These form a system which I have called the α system. Nearly all the remaining heads fall into two other singlet systems, the β system, consisting of a number of very diffuse bands in the blue, and the γ system, consisting of a large number of bands in the green and yellow. The heads of the three systems can be represented by the following formulæ:

α system —

$$\nu = 27371 + [254{\cdot}7(\nu' + \tfrac{1}{2}) - 2{\cdot}42(\nu' + \tfrac{1}{2})^2] - [387{\cdot}8(\nu'' + \tfrac{1}{2}) - 0{\cdot}63(\nu'' + \tfrac{1}{2})^2]$$

β system—

$$\nu = 21945 + [431{\cdot}1(\nu' + \tfrac{1}{2}) - 0{\cdot}83(\nu' + \tfrac{1}{2})^2] - [373{\cdot}5(\nu'' + \tfrac{1}{2}) + 0{\cdot}66(\nu'' + \tfrac{1}{2})^2]$$

γ system—

$$\nu = 18342 + [336{\cdot}3(\nu' + \tfrac{1}{2}) - 0{\cdot}19(\nu' + \tfrac{1}{2})^2] - [386{\cdot}5(\nu'' + \tfrac{1}{2}) - 0{\cdot}59(\nu'' + \tfrac{1}{2})^2]$$

It is probable that the α and γ systems have the same final level. It does not seem possible to come to any definite conclusion whether this is also the final level of the β system, as the measurements are probably not very accurate, owing to the extremely diffuse nature of the bands.

Work on the fine structure which is at present in progress indicates that the α system is due to a ${}^3\Sigma \rightarrow {}^3\Sigma$ transition.

It is hoped to publish full details in the autumn.

History of Research in Cosmic Rays.*

By Dr. ROBERT A. MILLIKAN,
Norman Bridge Laboratory of Physics, California Institute of Technology, Pasadena.

IN general, discussions of priority, save perhaps in the hands of the historian of science, seem to me to serve no useful purpose, since they represent, in the main, the *ex parte* statements of persons who are not in position to form scientific, objective judgments. The task properly belongs to posterity. The real scientific worker, whose primary interest is in the progress of science, can scarcely take the time to enter into these discussions even when he himself is badly misrepresented for the time being. In any case he may usually count on the facts ultimately coming to light.

In order, however, that the uninformed public may not be too long misled by the quite unusual number of incorrect statements and implications that have been made in recent discussions in both the popular and the scientific press upon the subject of 'cosmic rays' (and I have never, directly or indirectly, by implication or suggestion used or authorised any other name, and I know of no other designation which is as appropriate). I am now issuing, at the urgent request, especially of some of my German friends, this single statement, partly to direct attention to some facts quite generally overlooked, and partly for the sake of requesting anyone who is interested in forming an unbiased judgment to read for himself first the articles that I have written, either alone or in collaboration, rather than to depend for his impressions upon reviews or newspaper headlines of any sort. For these latter, whether unduly favourable or unfavourable (and both sorts have appeared), I obviously have no sort of responsibility and I cannot possibly find the time to correct all the erroneous statements that appear.

My own articles, on the other hand, and those published in collaboration with others (and the chief ones here involved and for which I have any responsibility are those represented by the subjoined references (1-9), have been written with the most careful effort to give the correct historical perspective to the field as it existed at the time our own results reported in these articles were obtained, in so far as the brevity necessitated by the nature of the articles permitted, and my attention has not yet been directed to any erroneous statement, implication, or oversight in our presentation of the essential history of the subject. Indeed, before these particular articles were submitted for publication, they were read and approved (as my more important papers usually have been) by three of the best informed physicists of my acquaintance, one of them an outstanding European, for the very purpose of getting the most trustworthy possible judgments as to essential correctness of statement and implication.

In spite of these precautions, misunderstandings seem to have arisen and a spirit of unfriendliness and suspicion of motives to have been engendered which I can account for only upon the assumption that it is another unfortunate aftermath of the War. This spirit, illustrated by the title "Zu Abwehr . . ." of an article found on p. 705 of *Physikalische Zeitschrift*, **19**, has led the authors to make altogether unjustified charges, to which my German friends have urged me to make some reply so as to prevent, in so far as it is still possible to do so, the further spread of misunderstandings. I can do so in a brief article only by presenting again the most essential elements in this history and by referring for more complete bibliographies to such excellent treatments as are found, for example, in Meyer and Schweidler's "Radioactivität" (Teubner, 1927), Chapter vii. pp. 546-624. These authors show an admirable objectiveness in their presentation, and give quite as complete a bibliography as could be expected, though the present article will perhaps add a few more to their list of references useful for succeeding editors.

The most significant contributions of my associates and myself to this whole field of cosmic rays have consisted (1) in obtaining experimental ionisation-depth curves that show that the cosmic rays have the structure of spectral bands of such frequencies or penetrating powers as to be interpretable, if Einstein's equation and Aston's curve are correct, not at all in terms of radioactive or disintegrating atomic processes, nor yet in terms of many-million-volt electronic impacts (up to 400,000,000) as we had earlier thought likely, but rather, as we interpret the evidence, in terms of definite atom-building processes; (2) in obtaining *experimental evidence* as to where these atom-building processes seem to be going on.

I have never even attempted in preceding articles to trace the origin and history of the *speculative* idea of atom-building in cosmic processes—a difficult matter, since it has been well nigh universal property for more than twenty years, but if it will assist the historian of this field I shall be glad to recount here the history of my own knowledge of the subject.

So early as 1904, when I was engaged in a study of the ratio of the radioactivity and uranium content of certain ores,[10] Prof. F. R. Moulton came to me at the University of Chicago with the statement that, if the sun had been originally pure uranium, it would not have been able to pour out so much energy as was demanded by what he regarded as trustworthy estimates of its minimum lifetime, and that therefore cosmogony demanded some thus far unknown source of stellar energy.

Now, this source had, in fact, already been found, though I myself was not at that time wise enough to appreciate it, for the interconvertibility of mass and energy had, in fact, been experimentally demonstrated for special cases by the Kaufmann experiments of 1901, and the facts of radiation

* This article is one of which I sent a German translation to the *Physikalische Zeitschrift* more than a year ago, but at the date of writing, April 1930, it had not appeared.

pressure, discovered a little earlier, were equally significant. Einstein a couple of years later set up this interconvertibility as a general consequence of the special theory of relativity,[11] and from that time forth it was available to every one who like Prof. Moulton was seeking a new source of energy for interpreting stellar lifetimes. Certainly within less than a decade from that time it had become the subject of common table talk about the University of Chicago. Further, so soon as in 1913-14 the Moseley relations and the facts of isotopes became established, atom-building within the stars with the transformation into radiant energy of the 0·0078 gm. which disappears for every gram-atom of hydrogen that goes over into helium, then thought because of alpha-ray phenomena to be the intermediary by which hydrogen is built into the structure of the heavier elements, became universally recognised source of stellar heat. Harkins (*Phil. Mag.* **30**, 723, 1915) discussed at great length this loss of mass, or 'packing effect', in atom-building. I reviewed it in the first edition of my little book "The Electron", p. 203, published in 1917. Its insufficiency to account for the whole of stellar energy was pointed out later. In a letter to NATURE (**99**, 445; 1917) Eddington mentions the idea of the entire annihilation of matter by the falling together and the complete overlapping of the fields of positive and negative electrons and ascribes the idea to Jeans (NATURE, **70**, 101; 1904).

Thus, certainly so early as 1915 the idea of atom-building out of hydrogen as a source of stellar energy and, so early as 1917, the idea of atom annihilation as a more potent source of such energy, had found their way definitely into the literature of physics and had presumably been current in physical laboratories other than that at Chicago from still earlier periods, for they are both obvious deductions from the Einstein equation (1905) and the facts of isotopes (hydrogen having an atomic weight of 1·008 instead of 1).

In our discussions at Chicago, W. D. MacMillan in particular always insisted on going one step farther and on abolishing the idea of the 'heat-death' by assuming that atom-building took place *in outer space* through the condensation there of radiant energy into atoms. He discussed this with me fully in 1915, and in July 1918 [12] he published these ideas in full. Any one interested in the history of this subject should read his other articles,[13] for he has been the chief advocate from the theoretical side of the idea of the evolution of cosmical energy through atom-building processes.

These three ideas, then, (1) atom-building out of hydrogen, (2) atom annihilation, and (3) the possibility of the condensation of the energy of radiation into atoms, especially the first two, are the ideas which we have subjected to certain sorts of *experimental* tests in our cosmic ray work. We have heretofore not been concerned at all with assigning priorities as to their *speculative* inception, and have made no attempt to do so, since our task has been merely to show how our experimental results bore upon these now widely current conceptions. We put forward the first bit of quantitative experimental evidence from the point of view of the cosmic rays when in 1925 we pointed out that our highest observed wave-length corresponded, according to our mode of computation used at that time, exactly to the energy resulting in accordance with Einstein's equation to the formation of helium out of hydrogen, and in February 1927 we discovered much more trustworthy evidence that this process, and also certain other atom-building processes, are the actual cause of the cosmic rays.[14] Furthermore, we presented evidence to show that contrary to all preceding assumptions, so far as we can discover, unless it be MacMillan's, *these particular atom-building processes do not appear to be taking place in the stars at all, but rather in the depths of space.* If there is any one in the world, next to Einstein, who pioneered in developing the *theoretical* ideas for which we have found a certain measure of experimental support, it is W. D. MacMillan. Every one who after 1918 has attempted or shall attempt to record the history of speculative ideas about atom-building in cosmic processes should certainly make reference to his work.

So much for the early history of atom-building ideas as I have personally come into contact with them. They may have been developed independently in other places also, but if so I have known nothing of it.

Now as to the experimental history of the penetrating radiation, a part of which is now known to be due to cosmic rays. This was what Dr. Cameron and I presented as accurately and as fairly as we knew how to do in the brief time available in the particular address published in NATURE in 1928 that is criticised in the foregoing reference, and I hope that my readers will all read it for the sake of judging both of its spirit and its facts. Any additions that need now to be made can best be grouped about the answers to the criticisms.

The address itself was one which I was asked to give as a popular evening lecture before the British Association for the Advancement of Science at Leeds in September 1927. It consisted in a report upon the then recent work of Dr. Cameron and myself on cosmic rays. In presenting our "New Results", I was very careful to avoid giving the impression that our work stood all by itself, and to emphasise this point I told my audience that my subject presented "a very beautiful illustration of the slow step-by-step process by which most advances in science are made, each experimenter building upon the past, but pushing on, if he is fortunate, a little beyond where his predecessors had gone", etc. I did this solely for the sake of disclaiming undue credit to ourselves for the work that was to be presented, and at the same time of stating a profound truth generally overlooked by the public, and actually one extraordinarily well illustrated by this subject, as even a superficial familiarity with its history will reveal to any unprejudiced observer. I had no thought of discrediting, and did not in any way discredit by that statement, as I am assumed in the foregoing review to have been attempting to do, the work of any of

my predecessors, the essential elements of whose contributions I then proceeded to state precisely as the record, as I read it, reveals them.

Dr. Kolhörster was in the audience, and afterward in friendly private conversation suggested no corrections and made no adverse comment of any kind, so that whether he was in complete agreement with my reading of the records or not I had every reason to suppose that his spirit was friendly. Also, so far as the historical introduction to that address is concerned, the spoken address was essentially the same as the written address, save for the insertion of the references in the footnotes. Since that time, however, the spirit of distrust and suspicion seems to have developed to such an extent as to call forth the exceedingly ungenerous and untrue charge that we have deliberately borrowed ideas from Nernst and from v. Schweidler without giving them credit. ("Die Ergebnisse dieser beiden Autoren werden von Millikan and Cameron Duchweges benutzt aber nirgends citiert.")

Now, the facts are that I have never seen a word written upon this subject by my friend and former teacher, Prof. Nernst, and knew only from Dr. Kolhörster's articles, and very recently from Prof. v. Schweidler's excellent book "Radioactivitat", page 607 *et seq.*, published in 1927, that Prof. Nernst had suggested a localised origin of the rays, which was not in keeping with our own findings of their uniform distribution throughout the heavens. Therefore, for the sake of not directing attention to a divergence of views as to origins, or asserting the incorrectness of any one's conclusions, I contented myself with merely stating briefly the experimental fact that Dr. Cameron and myself had brought to light thus far "no directional effect in cosmic rays at all", which is "at variance with results reported by Büttner and Kolhörster". It would be difficult to find anywhere a more complete inversion of fact or of motive than that existing between the real situation and the situation implied in the critique of Dr. Kolhörster *et al.*

Further, as to borrowing theoretical ideas from Prof. v. Schweidler's able writings, we have not only never attempted to advocate or even discuss the view attributed to him of a "gleich mässig verteilten strahlender materie", but also we were not pretending in the article in question to be doing anything more than presenting our *new experimental evidence* which we, at least, had found very helpful in enabling us to differentiate definitely between the three possible theoretical hypotheses which had been discussed so repeatedly as to have become common property so early as 1909, and were variously favoured by different competent workers [15] up to 1926, namely:

1. The hypothesis of an extra-terrestrial origin;
2. That of a radioactive stuff spread through the upper atmosphere; and
3. That of a radioactivity spread through the earth's crust.

It is hoped that any one who is interested in the history of this field will read the long summary and review, citing some scores of preceding articles that had already appeared by 1909 (*Physik. Zeitschr.*, **10**, 836; 1909). The reviewer, Kurz, discarded the first hypothesis, which he correctly attributed to Richardson, 1906, and also the second, and adopted the third as satisfying all the then known requirements, a conclusion which for the first time became completely untenable because of Gockel's balloon observations in 1910 and 1911, observations in which in three different balloon flights, all yielding results in substantial agreement, it was definitely shown that the ionisation within an air-tight vessel is larger, as we stated, at high elevations (up to 4500 metres) than at low, while Kurz and others had by 1909 presented definite tabulated computations showing that with the earth as the source the ionisation would have to fall to practically zero in going up as much as a thousand metres. Gockel's actual readings taken in two flights with electroscopes definitely arranged to maintain the pressure of their surroundings, in the third presumably doing so unintentionally, and so interpreted by him,[16] were sufficient completely to justify as a whole the statement which we made and which our authors criticise. Indeed, we took this statement directly from Gockel himself, as well as from Hess,[17] for the latter says, "Gockels Messungen ergeben, wenn man auf normalen Luftdruck korrigiert, sogar eine schwache Zunahme der Strahlung mit der Hohe".

Further, the point of real significance here is simply the fact that the readings did *not* fall at all to zero at altitudes above 1000 metres, as they were obliged to do, as shown repeatedly so early as 1909, if the earth were the source of the observed effect, thus definitely disproving the hypothesis most generally favoured up to this time and forcing a return to one or the other of the hypotheses rejected by Kurz. We certainly then did not do anything but state the simple fact in saying that this was "the next important step" after 1903. Gockel is now dead and cannot state his own case, but this is the more reason for urging all interested to read the record and let it speak for itself. The next year Hess,[18] after repeating and checking Gockel's experiments, extending them to 5200 metres and making them more *quantitative*, spoke definitely in favour of a return to hypothesis No. 1, although suggesting also the possibility of No. 2,* and Kolhörster also favoured No. 1, in interpreting his experiments of 1913 and 1914.[19]

There were no more observations of any kind significant for this history, at least that I know of, until March and April 1922 when Bowen and I [20] made our high sounding balloon flights (15·5 km) for the sake of subjecting to a severe and crucial test hypothesis No. 1 now supplemented by v. Schweidler's [21] definite calculation from Hess and Kolhörster's most consistent data of $\mu/P = 0{\cdot}57$ per metre of water on the hypothesis that the rays

* Wigand in a comprehensive and admirable review (*Physik. Zeitschr.*, **25**, p. 13; 1924) summarises the situation up to 1924 as follows: "Die Hypotesen über den Ursprung der durchdringenden Höhenstrahlung sehen die Strahlungsquelle entweder ausserterrestrisch im Kosmos oder in den höheren Schichten der Erdatmosphäre (Hess, 28, 33), v. Schweidler, Seeliger. Aus dem mannigfachen Für und Wider lasst sich noch kein klares Bild erkennen, und man muss vorerst noch mit mehreren Möglichkeiten rechnen." Those interested in understanding the facts developed up to 1924 should read this article in full.

Supplement to NATURE

No. 3166 JULY 5, 1930

The Metal Crystal.*

By Sir HAROLD CARPENTER, F.R.S.

WHEN prepared by one of the usual methods, metals and alloys consist of an aggregate of small allotriomorphic crystals. Pure metals usually consist of a large number of similar crystals. Alloys are sometimes composed of one type of crystal, though usually they contain two or more different kinds. In both cases metals as ordinarily prepared contain anything from about one hundred thousand to several millions of crystals per cubic inch. In all metals, however, the individual crystal is the unit of which the aggregate is built. It is therefore the simplest form of metal.

The size and shape of the crystal depends on the type of mould in which the fluid metal is cast and on the rate of cooling, and in any given casting crystals of various types may be obtained. In the casting of a steel ingot, for example, a layer of 'chill' crystals form in contact with the surface of the mould. Attached to these columnar crystals grow nearly at right angles to the surface, while in the interior, equiaxed crystals result, which are due to the separation of minute crystals in the liquid which grow and form interference boundaries (Fig. 1). In addition to these, skeleton crystals grow on the surface and sometimes also in the cavity produced by shrinkage in the upper part of the ingot. During the subsequent mechanical treatment to which the metal is subjected, these crystals change their shape. If the mechanical work is severe, they are fragmented and eventually complete recrystallisation takes place with the birth of new crystals. Whether, therefore, a given metal or alloy is used either as a casting or in some worked form, it always consists of an aggregate of crystals.

The properties of metals and alloys in the ordinary state, accordingly, are the properties of these *aggregates*. As already mentioned, the individual crystal is the unit of which these aggregates are composed. Even if it possessed directional properties, these would not be revealed by any tests on polycrystalline material, since the individual crystals are oriented in many directions, and the directional properties would be cancelled out. In addition to this, however, the properties of the crystal boundaries themselves have to be considered. The finer the aggregate, the larger the area occupied by the boundaries. It has long been known that the boundaries in a crystal aggregate are stronger than the interiors of the crystals. For example, a metal fractures under tensile test through and not round the crystals. One of the commonest methods of increasing the strength of a metal or alloy is to diminish its crystal size and increase its boundary area by suitable thermal and mechanical treatment. The properties of any given metal, therefore, are the resultant of those of the very numerous individual crystals of which it is composed, oriented in many positions, modified by the properties of the crystal boundaries.

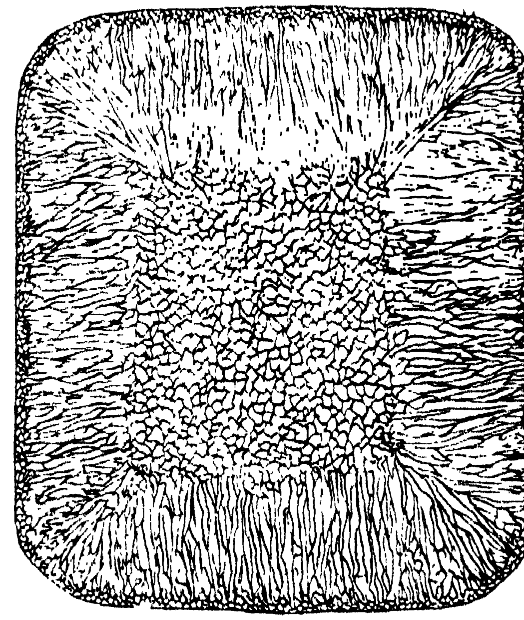

FIG. 1.—Section of steel ingot showing three types of crystals. Outside layer, small chill crystals. Intermediate layer, columnar crystals. Inside layer, equiaxed crystals.

If it were possible to study the properties of the individual metal crystal, the variables which have just been mentioned would be excluded, and the observations made would be of fundamental scientific value. Any particular property of the metal crystal itself could be studied, the only

* Discourse delivered at the Royal Institution on Friday, May 30.

variable being its orientation. It would thus enable the test to be made whether the property in question was directional. From a scientific point of view, therefore, the study of individual metal crystals should precede that of aggregates. Owing to the fact, however, that special conditions have to be observed if a metal is to be obtained in the form of a single crystal, the order of investigation has in practice been just the opposite.

It was the realisation of this fact which gave rise about twelve years ago to definite attempts on the part of investigators to prepare single metal crystals. Considering its great scientific importance, it is perhaps surprising that the attempt was not made earlier, but it is clear that it could not have been made with any real prospect of success until the technique of metallographic research had reached the necessary stage of perfection.

Looking at the problem of preparing a given piece of metal in the form of a single crystal, it is theoretically capable of solution in at least three different ways:

(1) By production of the crystal from the vapour phase.

(2) By its production from the liquid phase.

(3) By the conversion of the solid metal in the ordinary polycrystalline aggregate into a single crystal.

Success has been achieved in each of these ways. To-day there are nine methods of producing single metal crystals—two from the vapour, three from the liquid, and four from the solid phase. Each of these is an example of what may be called *controlled* crystallisation, and the investigation of any particular metal divides itself into three parts: (*a*) The production of the crystal itself; (*b*) the determination of its orientation; and (*c*) the study of its properties. The last category may be divided into two sub-categories, according as the investigation either does or does not involve the distortion of the crystal.

Production of Single Crystals from the Vapour Phase.

Two methods are available, each of which is based upon the technique developed in the incandescent lamp industry for depositing tungsten metal on a glowing wire. One is due to Koref,[1] the other to Van Arkel.[2] Both methods start with a single crystal obtained by another method. This serves as a nucleus and grows to a large single crystal. As an example the production of single crystals of zirconium by J. H. de Boer and J. D. Fast[3] may be described. There is a special interest about this method in that not merely has it enabled this metal to be produced in the monocrystalline form, but also that it has for the first time led to its production in the pure state, in which, whether mono- or polycrystalline, it is ductile, whereas as previously prepared it has always been found to be brittle. This is now known to be due to small traces of impurities.

The principle of the method is the deposition on a glowing metal filament of the metal in question by the thermal dissociation of a volatile compound. The essential condition for success is that below the melting point of the metal to be prepared a temperature range must exist in which the vapour pressure of the metal is smaller than the partial pressure of the metal in the vapour phase. In this particular case the metal filament consisted of tungsten and the compound in question was zirconium iodide. It is not necessary to prepare the iodide at the outset. A mixture of zirconium and iodine will do equally well. The tungsten filament, the diameter of which is about 40 μ, is heated by an electric current to a black-body temperature of 1800°, as read by an optical pyrometer. The reaction vessel made of pyrex glass is then placed in an electric furnace and heated to about 600° C. The zirconium powder and iodine combine to form the iodide and this compound then sublimes. It is decomposed by the filament at 1800° C. and the zirconium deposited on it. Free iodine is than available to combine with a fresh quantity of zirconium in the reaction vessel and the cycle of changes is repeated until sufficient metal has been deposited. The filament is cooled by the solidification of the zirconium and from now on the temperature has to be measured through the strongly coloured vapours of iodine and the iodide. The success of the experiment depends upon depositing zirconium at the correct temperature. This has been found to be about 1800° C. The current rises from an initial value of 0·25 for a filament of 40 μ to 200 amp., when the metal has grown to a diameter of 5 mm. Whether the temperature of the filament falls or rises during the experiment depends upon the external resistance. If this is small the strength of the current is determined by the filament itself. As this grows its resistance falls in proportion to the square of the diameter, whereas cooling by radiation is proportional to the diameter. Therefore, the temperature of the filament tends to rise, and this must be prevented by increasing the external resistance. Conversely, if the external resistance is large, this determines the current, and the zir-

conium rod, which is continually becoming thicker, tends to cool.

If the temperature of the filament is kept at 1700° C., the zirconium deposited is polycrystalline. Between 1750° and 1850° C. the crystals of zirconium are so large that only one occurs in the cross-section of the wire and the built-up rod consists of a series of single crystals of from 0·5 cm. to 1·5 cm. long built round the tungsten nucleus. The crystals thus formed are found to be hexagonal prisms. If the temperature is allowed to rise to 1900° C. the zirconium grows very rapidly at first, but before long it reacts with the tungsten filament and forms a eutectic.

This method is suitable for preparing single crystals of the high-melting lamp filament metals. Van Arkel and de Boer have applied it to titanium, hafnium, and thorium. Koref in co-operation with Fischvoigt [4] has succeeded in preparing single crystals of molybdenum, tantalum, iron, zirconium, and titanium by his method. It is possible, therefore, by either of these methods to prepare single crystal wires and thin rods of high-melting metals, provided the vapour of the compound of the metal with iodine satisfies the condition described above.

Production of Single Crystals from the Liquid Phase.

Brief mention may be made of two of the methods available. These have been used mainly for preparing single crystals of low-melting metals in refractory glass containers, but they can also be applied to metals and alloys of higher melting points in suitable containers.

The first method is that devised by Czochralski,[5] who prepared long thin threads of crystals by drawing them out at a particular rate from the molten metal contained in a crucible just above the freezing temperature. The metal is drawn upwards by means of an auxiliary wire moving vertically at a uniform rate. At some millimetres above the surface of the molten metal solidification begins. The rate of movement of the auxiliary wire has to be the same as the speed of crystallisation. If it is too quick, the single crystal wire breaks ; if too slow, polycrystalline wires are produced. In this way single crystal wires (0·5 mm. diameter) of tin, lead, and antimony have been prepared. This method was developed further by Gompers (1922) and Mark, Polanyi and Schmit (1923).

Single crystal rods up to one inch in diameter can be grown by the second modification due to the work of Tammann (1923), Obreimow and Schubnikow (1924), and Bridgman (1923–25). In Bridgman's method the molten metal contained in a suitable closed tube of refractory glass or quartz is slowly lowered through a tubular electric furnace in a vertical position, and kept at a temperature somewhat above the melting point of the metal in question. The lower end is tapered to a point, which is the first to emerge from the furnace. Solidification starts here and proceeds slowly upwards. Provided the rate of lowering is less than the velocity of crystallisation and sufficiently slow for the latent heat of solidification to be dissipated by conduction, the metal usually crystallises as a single crystal, and in this way Bridgman prepared single crystal bars of tin, cadmium, zinc, antimony, bismuth, and tellurium.

This method depends for its success upon the formation of only one nucleus, upon which the solidifying metal crystallises uniformly. If, however, crystallisation starts from more than one centre, then some means must be found of confining the growth to one crystal. The best way to meet this difficulty was found to be by drawing the lower part of the tube out into a separate chamber separated from the main part by a capillary 0·1 mm. in diameter. This acts as a filter and allows only one of the several crystals which may have formed initially in the lower bulb to get through into the main part of the tube. It is this crystal which then grows and forms the single crystal test-piece.

Bridgman's experiments were carried out by allowing the crystal to form *in vacuo*, and the elimination of all dissolved gas is therefore an essential condition of the success of this method. The rate of lowering depends both on the metal and the size of the tube. In the case of bars 2·2 cm. in diameter, a speed of about 4 mm. an hour was found to be suitable. For bars of small diameter, however, speeds up to 60 cm. per hour could be employed.

The removal of the single crystal bar from the tube is an operation requiring great care. If the containing vessel is perfectly clean, the metal sticks and cannot be removed without distortion. The tube must therefore be greased. A convenient way to do this is to flush out with a heavy mineral oil and then wash this out with petroleum ether. The tube is then heated so as to remove the ether, but a thin film of oil clings to the glass and is sufficient to prevent the metal from sticking.

Davey [6] modified Bridgman's method by using a graphite tube, and succeeded in making single crystal copper test-pieces six inches long and nearly

one inch in diameter. Miss Elam[7] has shown that single crystals of copper, silver, and gold can be grown in graphite tubes in an atmosphere of nitrogen. This has proved to be an advantage, since when grown in this way the metals are quite sound, whereas if melting is carried out *in vacuo* there is a liability for the resulting rod to contain blow-holes. Here also the greatest care is required in removing the crystals, particularly of soft metals, from the containing tube. On one occasion it was found on removing a single crystal rod of gold that it was twisted into a spiral showing three complete turns.

Production of Single Crystals from the Solid Phase.

The problem here consists in the conversion of a polycrystalline into a monocrystalline metal. Success has been reached in this case by the utilisation of an observation made by Sauveur[8] in 1912. He showed that by carefully straining and afterwards heating certain metals, crystals of a larger size could be produced, and suggested that there was a *critical stress* which produced the largest crystals. Later, Ruder,[9] Chappell,[10] Jeffries,[11] and Hanson[12] have shown that if a metal is locally deformed and then heated, exceptionally large crystals form at some distance from the point at which the stress is the severest. If a tapered test-piece is used, a strain gradient is obtained, and the largest crystals always form within the strained region, but farther from the area of greatest strain the higher the temperature. Seligman and Williams[13] stretched aluminium sheet which had previously been heated to various extents and found on heating that, up to a certain point, a small deformation had no effect. Beyond this point, however, large crystals were formed, and as the deformation was further increased the crystal size was diminished. The crystals produced by these methods were very large compared with those in the original metal, some of them being 0·5 in. long.

Single crystal test-pieces were first produced from the polycrystalline metal in the case of aluminium by the following series of treatments:[14] (1) The metal has first to be softened completely, recrystallised, and converted into new equiaxed crystals so far as possible of uniform size. The most suitable size has been found to be 36 per square millimetre. This condition was produced by heating the metal for six hours at 550° C. (2) These crystals must then be strained to the required amount. The precise degree of strain for the aluminium used was an elongation of 1·6 per cent on three inches, produced by a tensile stress of 2·4 tons per square inch. (3) The strained crystals have afterwards to be heated in such a way that the potentiality of growth conferred by strain can be brought fully into operation. This final heat treatment was begun at 450° C., and the temperature raised about 25° C. per day up to 550° C. It was finally raised to 600° C. for one hour in order to complete the absorption of small crystals on the surface which persistently remained at lower temperatures.

The boundary of the single crystal thus produced extends at each end in the form of an irregular surface into the head of the test-piece (Fig. 2), and by

A B

this means single crystal bars of aluminium have been prepared, the diameter of which was 0·564 in. and length about 8 in. Polycrystalline bars 0·798 in. in diameter have been converted into single crystals over a length of 4 in. In this way, upwards of seven million of the original crystals can be caused to coalesce into a single crystal. How delicate the process of adjustment of strain is may be judged from the fact that its precise value has to be determined for each fresh batch of aluminium even though the metal is of the same 'works' composition. On an average, one experiment in four succeeds in producing a single crystal test-piece. To give one illustration: the result of

treating a batch of twenty polycrystalline test-pieces was that seven were converted into one crystal, eight into two crystals, four into three crystals, and one into four crystals.

This method has been successfully applied by Edwards and Pfeil[15] to the production of large crystals of iron. It has also been utilised by Miss Elam[16] in the production of single crystals of solid solution alloys of zinc in aluminium. Schaller and Orbig have used it to prepare single crystals, wires of tungsten and molybdenum, while Altertum has prepared single crystal bars of tungsten by making use of the peculiar effect steam has on small tungsten crystals at high temperatures.

The production of single crystal test-pieces from polycrystalline metals by the method of critical straining followed by heating is a more complex process than that of the preparation of single crystals direct from the vapour or the liquid.

The deformation of a metal is possible on account of the existence of 'atomic planes' in each crystal. These are planes which can glide and slip along each other. In a single crystal bar where the orientation is uniform these planes function unhindered. In a polycrystalline bar, however, where the crystals are variously oriented, the movements are quite different. The first crystals to yield are those so oriented that they display the least resistance to stress. The degree of this is limited since they are held in a rigid matrix of other crystals. Hardening takes place along the slip planes and the movement is finally arrested. Limited slip then takes place on other crystals which now present the least resistance to the stress, and they in their turn are hardened. The process is then repeated in other crystals. The net result is that in this case the planes of slip are not uniform but bent. According to van Liempt,[17] "In this way strains are produced in the crystal because the original distance of the atoms has not remained quite the same and the electron lattice has been distorted. The deformed metal is now in a labile condition. The lability is locally the greater as the strain increases. If the deformed metal is now brought to a high temperature there will be an inclination to return to the stable condition."

The method of critical straining consists in straining the crystals of an aggregate in such a way that when it is heated only one of the crystals recrystallises and forms a nucleus. On continuing the heating, the remainder of the crystals, which are in a labile condition, gradually recrystallise and aline themselves on the single nucleus. Ultimately, therefore, a single crystal bar is obtained. If, however, the bar were heated at a higher temperature, a number of strained crystals would recrystallise forming nuclei, and each of these would act as a crystallisation centre. The result would be a bar containing as many crystals as there were nuclei. The reason why in any given set of experiments only some of the bars become monocrystalline is that it is not always possible to ensure that only one labile crystal recrystallises in the first instance. This method, in fact, permits crystals of any desired average size to be grown from a polycrystalline aggregate, since it is only necessary to adjust the degree of strain and the temperature to the requisite condition. In this respect it is the most general of the methods available for preparing large crystals. Moreover, it is quite independent of the melting point of the metal or alloy. In another sense, however, it is more restricted since it depends on the response of the crystal lattice to stress and the liability of the metal or alloy to form twin crystals on being heated. If such liability exists, single crystals cannot be prepared by this method.

Orientation of the Crystals in Single Crystal Test-pieces.

The only satisfactory method of determining the orientation of the crystals is by X-ray analysis. The original method of determining the crystal axes was worked out by Müller.[18] It involves the preparation of bars of square section and the photographing of the reflections from the crystal planes. A special arrangement is required for mounting the bar so that it can be rotated on a vertical axis and photographed in the desired positions. Müller found that the reflections from unstrained bars are perfectly clear and sharp and are obtained within a narrow setting angle, whereas, if the bars are strained, the reflections become 'fuzzy' and are spread over a wider setting angle, the width of which increases with the extent of the distortion. In Müller's method the data can only be obtained for a very thin surface layer of the test-piece. The measurements which he made, however, on the various parts of the surface, showed that this layer had the same orientation relative to the reference plane over the whole surface. It seems probable, therefore, that the same thing holds for the entire rod.

I will now deal briefly with two questions to which the method of X-ray analysis gives definite answers: (1) Are the single crystals obtained in the various ways I have described perfect crystals in the sense that the orientation of their atoms is

uniform corresponding to the crystal symmetry, and are they free from strain? It will of course be realised that owing to their method of preparation they cannot, with one exception, possess the external forms but only the internal symmetry of crystals. The particular exception to which I refer is the case in which they have been produced from vapour, and here, provided suitable conditions are maintained, the crystal wires do show the external forms of crystals. So far as they have been tested, single crystal rods and wires prepared either from the vapour or the liquid phase show themselves perfect crystals when tested by X-ray analysis. This is very much what is to be expected, at any rate in the latter case, since the crystals have been deposited from the liquid by slow cooling under conditions in which no strain should be produced. But it is interesting that the reflections obtained from aluminium single crystal test-pieces, grown from the polycrystalline solid by the method of critical straining and heating, are also perfectly sharp and indicate the complete absence of strain, at any rate so far as the external layers of the crystals are concerned. It follows from this that the small strain set up in their production is completely removed by the prolonged heat-treatment to which they are exposed. This conclusion is supported by the fact that when such bars are slightly distorted the X-ray reflections immediately become less clear.

(2) Do the crystals grow more easily in certain positions than in others; that is, do they take up a preferential orientation? As yet no evidence is available on crystals deposited from the vapour phase. Bridgman concluded that the favoured position of growth from the liquid is that in which the principal cleavage plane is parallel to the axis of the crystal, and he has stated that in the case of large crystals of antimony, no specimens were found which were oriented in any other way. This, however, does not fix the orientation of the crystal, since this plane of cleavage may have any orientation within 180° about the axis of the casting. Miss Elam has shown that in the case of rods of copper, silver, and gold, grown from the liquid, there is no particularly favoured position. Considerable variations of position have been found by her in the case of crystals grown by the method of strain and heat-treatment, and the evidence on this point is now quite extensive.[19] Twenty-nine aluminium, twelve aluminium-zinc alloy, and ten iron single crystal test-pieces have had their orientations determined. In the case of aluminium, a great variety of orientation was met with, since the positions of the axes were found to be scattered over a wide field, but the majority of the crystals favoured a position near the (110) axis, and none has yet been obtained near either the (111) or the (100) axis (Fig. 3). Moreover, this was also found to be the case for an aluminium test-piece consisting of four crystals. In the aluminium-zinc alloy, a considerable variety of orientations was also found, but here it was the (110) axis which was avoided. Five out of twelve crystals were found to be near the (100) axis. In the case of iron a wide range of positions was found among the ten crystals. The (110) axis was avoided, but no evidence was found of any preferential orientation.

Summing up the evidence, it is clear that in the case of the fifty-one crystals, the positions of which have been thus determined, the method of straining and heat-treatment does not determine to any marked extent the orientation of the crystals which grow although certain orientations are avoided. Growth appears to be equally easy in a great variety of positions. The orientations which are avoided are no doubt those in which growth is more difficult. The problem of growing a single crystal test-piece in a desired orientation has been recently taken up and a certain measure of success has been obtained.[20]

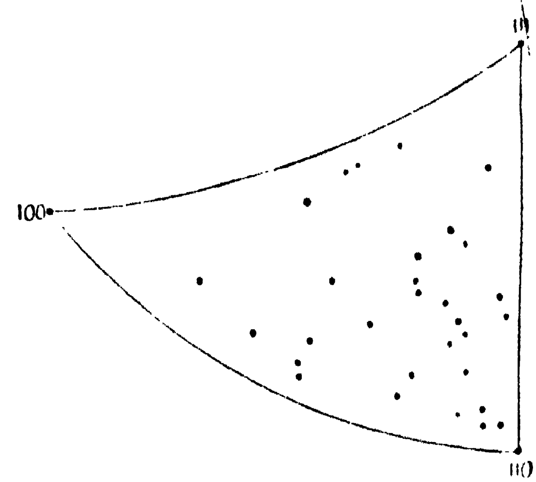

FIG. 3.—Shows the great variety of orientations met with among twenty-nine single-crystal test-pieces of aluminium. 111 (octahedral), 110 (rhombicdodecahedral); 100 (cube).

MECHANICAL PROPERTIES OF SINGLE CRYSTALS.

I have already had occasion to comment on the remarkable softness of single crystal bars, which necessitates great care in their handling and machining, and differentiates them from the same metals in the polycrystalline form. This is precisely what we should expect from a metal possessing the uniform orientation of a single crystal and constitutes strong evidence that the bars really

are single crystals. It has been known since the work of Ewing and Rosenhain at the end of last century that the plastic yielding of a metal is due to slip on certain planes along which it yields more easily than in other directions. Even so, the ease with which single crystal bars of aluminium, copper, silver, and gold, and even iron, can be deformed is astonishing. Each of these metals can be bent very readily, but once it has been bent to any marked extent, a higher stress is required to make it revert to its original shape. This simply means that it has been hardened under distortion and the uniform crystal pattern of the atoms altered. Whether this is due, as Miss Elam and I have suggested, to the uniform bending of the crystal planes, or whether, as Gough, Hanson, and Wright have suggested, the distortion of the crystal plane is such that the average curvature is small and of the nature of 'rumpling', cannot as yet be decided.

The softness of single crystal bars indicates that they can only possess a very low limit of proportionality under stress, and indeed raises a doubt whether they can properly be described as possessing any limit of proportionality at all. This point has been carefully tested by Gough, Hanson, and Wright [21] in the case of the metal aluminium. The limit of proportionality in tension of a polycrystalline bar is just about one ton per square inch. These investigators found that the single crystal bars possess no primitive limit of elasticity, but plastic straining occurred under the least stress applied. Furthermore, they conclude from the slope of the stress-strain diagram, even at the 10-40 lb. range of load, that no primitive state of elasticity existed. It is clear, therefore, that the well-defined elastic limit found in the polycrystalline bar is not a property of the metal crystal, but of the crystal aggregate in the case of aluminium.

The common and useful metals belong to one of three types of crystal structure, the face-centred cubic, the body-centred cubic, or the close-packed hexagonal lattice, and it is significant that each of these represents a very high degree of crystal symmetry. These have certain structural features in common. Planes of atoms exist in which the units are closer together than they are to their neighbour in the next plane. Even in the same plane, however, there are certain lines in which the atoms lie closer together than they do in other directions. When a crystal is stretched or compressed it tends to yield on certain planes and along certain directions in which the forces binding the crystals together are the weakest.

Single Crystals of Aluminium.

The deformation and ultimate fracture of a single crystal test-piece was first carried out in the case of the metal aluminium. The first experiments were qualitative, and showed at once that the tensile properties of this metal are directional. On one hand, a round polycrystalline bar pulls out like an isotropic material. It undergoes general extension, and finally breaks with considerable reduction of area and yields a cup and cone fracture (Fig. 4).

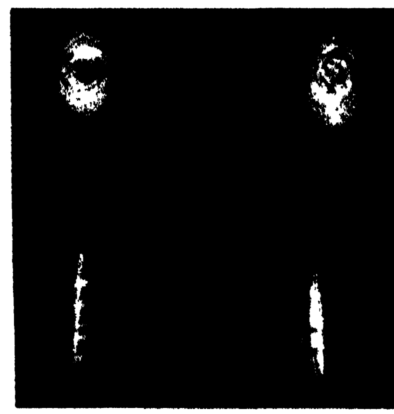

FIG. 4. Upper half, fracture of polycrystalline test-piece yielding cup and cone fracture. Lower half, fracture of single-crystal test-piece yielding 'wedge' fracture.

This is the result of bent slipping. The cross-section of the test-piece is round at any point, although the surface is roughened, due to the unequal distortion of the minute differently oriented crystals. On the other hand, when a round single crystal bar is distorted under tensile stress, it becomes an ellipse. As distortion proceeds the ellipse becomes sharper and sharper. A point is reached when a curious and characteristic lens-shaped figure, inclined at an angle to the long axis of the test-piece, makes its appearance. Finally, the bar breaks at this point with a characteristic 'wedge' fracture (Figs. 4 and 5). In this test the surface of the test-piece is not roughened, but is mechanically etched with numerous slip lines, which are known as 'glide ellipses'. Considerable variations in the ductility and ultimate stress of different test-pieces are found to be due to differences in the orientation of the single crystal, relative to the axis of the test-piece. The ductility is in some cases nearly three times as great as in the polycrystalline bar, whereas

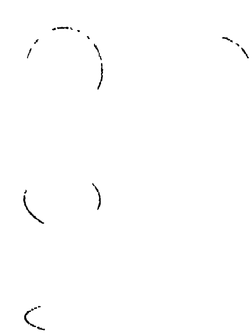

FIG. 5.—Shows stages in the reduction of a round single-crystal test-piece of aluminium in a tensile test leading to the production of a 'wedge' fracture.

the ultimate stress is considerably less and in no case exceeds 80 per cent of that of the polycrystalline metal.

The first complete mathematical and quantitative analysis of the distortion of a single metal crystal was also carried out on aluminium, and forms the subject of the Bakerian Lecture by Taylor and Elam in 1923.[22] The analysis was carried out on a square bar machined from a round bar and involved the marking of each face with a scratch parallel to the length of the axis of the specimen, and by cross scratches at 0·5 in. intervals. The dimensions of the test-piece were 1·0 cm. × 1·0 cm. × 20·0 cm. The faces were numbered 1, 2, 3, 4, so that when the specimen was placed upright in the testing machine the faces appeared in this order when the observer moved round the machine in an anti-clockwise direction. At each successive stage of the test, the extension between each pair of cross marks was measured on each face. The angles between cross scratches and longitudinal scratches were also measured. In addition, the thickness of the specimen between the pairs of opposite faces, and the angle between neighbouring faces, were also measured. These sufficed to determine the nature of the distortion (Fig. 6).

These investigators found that up to an extension of 40 per cent elongation the crystal distorted by slipping or shear on one plane. This plane was found by X-ray measurements to be an octahedral plane (111) of the crystal. The direction of shear was also determined and found to be along one of the three principal lines of atoms in the octahedral plane. When the specimen was extended beyond 40 per cent elongation, it was found that the distortion was no longer due to slipping on one plane. This was explained by the authors, who showed that the effect of the shear was to rotate the axis of the specimen relative to the crystal axes in such a way that another octahedral plane came into a position where its inclination to the axis was the same as that of the slip plane. In these circumstances it

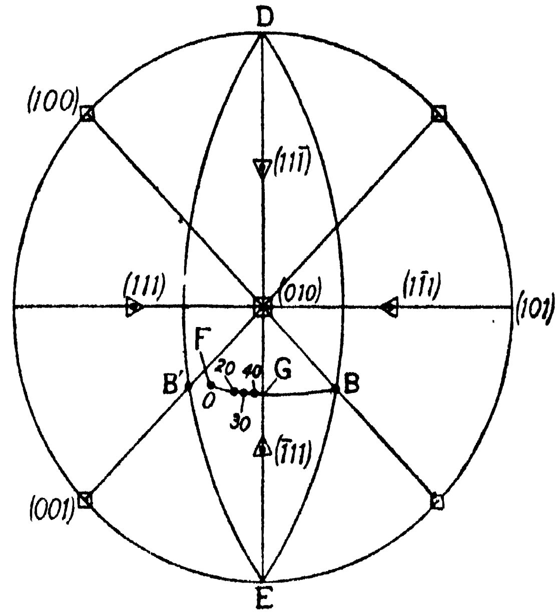

FIG. 7.—Shows the position of the axis of the specimen relative to the crystal axes at 0%, 20%, 30%, and 40% extension. (Reproduced by courtesy of the Royal Society.)

was clear that slipping might occur on both planes simultaneously, and it was verified that this was the case (Fig. 7).

This investigation furnishes the explanation of the drawing down of round single crystal test-pieces of aluminium in the tensile test into very acute ellipses. It is due to the slipping of the crystal on two conjugate planes. It also established a further important point. Hitherto, the evidence with regard to the yielding of a metal by slip had been purely qualitative. It had not been shown that the deformation when a metal crystal is strained is such as could be produced by slip. The quantitative measurements in this paper showed for the first time that this is the case, and it has been left to Taylor and Elam to complete in this way the original discovery of Ewing and Rosenhain.

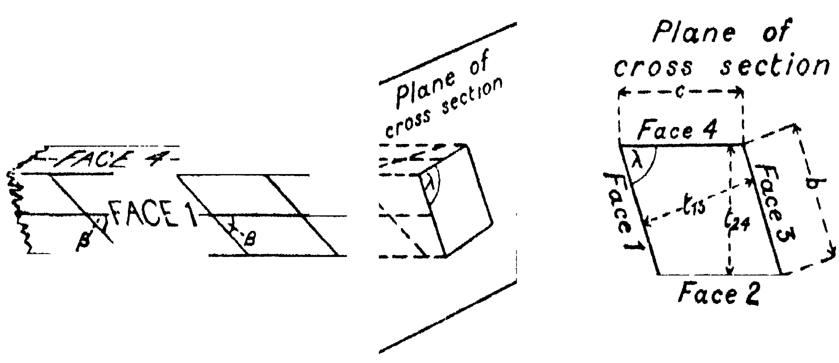

FIG. 6.—Scheme for marking and measuring the distortion of a single-crystal test bar of aluminium. (Reproduced by courtesy of the Royal Society.)

The second paper by Taylor and Elam,[23] on the plastic extension and fracture of aluminium crystals, contains a most interesting test. Previously they had analysed in a similar way the distortion of other single crystal bars in which slipping

·gins on one plane and afterwards continues on ·vo, when the bar has moved into the position of ·njugate slipping. They predicted that if the ·ystal axis of the unstrained crystal were origin·ly in the position where double slipping could ·cur, it should begin at once. Among the large ·mber of crystals grown by Miss Elam and ·yself, one was found the axis of which corre·onded very closely to this position. On dis·rting this in tension, it was found that double ·ipping began almost at once and continued ·roughout the whole of the remainder of the ·tension. Not only this, but also the amount slipping which occurred on the two planes was ·actically equal and the axis of the specimen ·arcely changed during the whole of the test. ·ne other conclusion also follows from these ·sts, namely, that whatever the original orienta·n of the crystal in the test-piece, it always ·eaks in the same position.

The question then arises, does the single crystal ·main a single crystal throughout the extension · to fracture, or does it break up? Evidence · this point is contained in Müller's paper (loc. cit.) the character of the spots reflected by X-rays. the unstrained specimen the reflected spots are ·ry small and only obtained within a small ·tting angle. When extension began the range reflection frequently increased, and the size the reflected spots became larger. Assuming ·at the material does break up into small crystals, ·is possible from the dimensions of the reflected ·ots to make a rough estimate of the maximum ·gle between the surfaces of a pair of these small ·stals. It was found that this angle amounted ·metimes to several degrees. Müller infers that ·is result shows the actual breaking up of the ·st-piece into smaller crystal aggregates. As, ·wever, these remain even after a considerable ·tension of the test-piece very nearly in the same ·sition, the test-piece can still be macroscopically ·nsidered as being a single crystal. A Laue ·otograph was taken of a test-piece at the very ·ge where the specimen was broken. The pattern ·ich resulted showed the existence of relatively ·ge crystals near the edge. It is clear from this ·at the metal crystal exhibits great resistance destruction by mechanical stress.

It is well known that when a metal is distorted tension it breaks by shear stress, and that this ·at a maximum at 45° to the long axis of the test·ce. Supposing that aluminium were a stronger ·tal and that it were possible to break it by ·ar stress on one plane, and supposing that we could find a single crystal test-piece the plane of slip of which was oriented at 45° to the longer axis, we should expect the fractured surface to be not a wedge but a plane surface inclined at 45° to the test-piece. Since we cannot do this with aluminium, owing to its weakness, it seemed interesting to discover whether it could not be hardened by the addition of alloying element which does not destroy its crystal symmetry, and that it might thus be made to have the property of slipping only on one plane before it fractured. Miss Elam succeeded in doing this by dissolving 18·6 per cent of zinc in aluminium, and this, in spite of the fact that the lattice of zinc is not face-centred cubic but close-packed hexagonal. This is a one-phase alloy. It was converted into a single

FIG. 8. Fracture of single-crystal test piece of aluminium-zinc alloy. The fracture has occurred almost wholly on one principal cleavage plane though there are signs of fracture on a second plane at 90° to it. Both planes make angles of 45° with the axis of the test-piece.

(Reproduced by courtesy of the Institute of Metals.)

crystal test-piece by the method of critical straining and heat-treatment and was then tested in tension. It pulled out almost entirely on one principal cleavage plane, although there were signs of a second plane on which slipping had occurred at approximately 90° to it. Both planes made angles of approximately 45° with the axis of the test-piece (Fig. 8). It is clear, therefore, that fracture did occur on the plane of maximum shear, which is in strict accordance with theory. So far as I am aware, this is the first time that it has been possible to test this.

Taylor and Farren, in a paper on the distortion of aluminium crystals under compression,[24] have found that this is of the same nature as that which occurs in tension. It is due to slip parallel to a certain crystal plane and in a certain crystallographic direction, and the choice of which of

twelve possible crystallographically similar types of slipping actually occurs, depends only on the components of shear stress in the material and not at all on whether the stress normal to the slipping planes is a pressure or a tension.

Single Crystals of Iron.

The study of the distortion of single crystals of iron has yielded results of quite remarkable interest. The lattice structure of this metal is different from that of aluminium. It is body-centred cubic, that is, there is an atom at each corner of the cube and one in the centre. The planes having the largest number of atoms and the largest distance between neighbouring planes are not the same as in the face-centred cubic lattice. For this reason alone, therefore, it was important to study the distortion of the single iron crystal. But there was a further reason. The slip bands of the majority of metals formed in plastic deformation are straight, whereas those of iron are nearly always curved. Nearly all previous workers in this subject have assumed that the iron crystal has a plane of slipping which is a crystal plane, and they have attempted to correlate the slip lines with the traces of crystal planes. These attempts have not met with success, but the work of Osmond and Cartaud [25] constitutes a notable exception. They pointed out that the slip lines which occur when an iron crystal is strained are curved, and they could find no relationship between these either as a whole or in their detail and the crystallographic planes.

Taylor and Elam studied the distortion in tension of single iron crystals prepared by Edwards and Pfeil.[26] They concluded that when an iron crystal is distorted in tension it does not slip along a crystallographic plane, but that the particles of metal "stick together along a certain crystallographic direction and the resulting distortion may be likened to that of a large bundle of rods which slide on one another. The rods stick together in groups or smaller bundles of irregular cross sections and the slip lines which appear upon the polished surface are the traces of these bundles on that surface." This conclusion has been tested by Gough, who subjected a single crystal of iron to alternating torsional stresses. The specimen was ultimately fractured by fatigue, precautions being taken to prevent the development of fatigue cracks to any great extent. Careful microscopical examination showed that the slip bands differed entirely in appearance at different portions of the specimen, but all bands could be described as belonging to one of the following types: (1) One set of straight parallel bands; (2) two sets of bands of differing slopes, those of each set appearing to be straight or nearly so; and (3) distinctly 'wavy' slip bands having a well-defined average slope and limits of slope but impossible to resolve into combinations of straight slip bands.

Gough's analysis led him to the conclusion that alpha iron does slip on crystal planes, but that instead of it always taking place along planes of one type, it may take place on any of the (112), (110), or (123) planes. It is only under very special conditions that any one of the planes will coincide with the plane on which the value of the shear stress resolved in the octahedral direction is the maximum. In general, therefore, slip will occur on two sets of planes simultaneously. It is this which gives rise to the generally curved nature of the slip bands and the very complicated arrangement of which the duplex and 'wavy' bands are types. This is the view of the distortion of the single iron crystal which is now generally accepted. The character of the slip accounts for a property of iron of the highest importance, namely, its tendency to break with a fibrous fracture.

Magnetic Characteristics.

Plasticity is only one of the properties of metals. It is the one of greatest importance to engineers and metallurgists, but from the general point of view of physics all properties are important. Physicists have recognised in single crystals a new approach to many of their problems, and each year this form of metal is being used to an increasing extent as a means of obtaining data on some of the fundamental phenomena of matter. Magnetic, electrical, thermal, and optical properties have been measured for crystals of many metals and of different orientations, and it is only possible to mention a small proportion of this work.

Investigations of the magnetic properties of single crystals of iron have been carried out by Honda, Kaya, and Mashiyama.[27] They prepared single crystals of iron wire 68·1 mm. × 2·4 mm. × 1·81 mm. by the method of critical straining and heating. They found that the hysteresis loss of a single crystal of iron is only one-tenth of that of ordinary transformer iron, and that it increases rapidly with increase in the number of crystals in unit volume. The initial and maximum permeabilities of iron were found to decrease with the number of crystals in unit volume.

A set of five crystal rods, of which three had heir axes approximately lying in the (100) plane, ınd two in the (110) plane, was prepared. The nagnetic expansion of these rods was measured, ,nd the following observations were made: 1) The magnetic expansion of single crystals of ron is generally very large as compared with that f ordinary iron. (2) The magnetic expansion n the direction of the tetragonal axis is always ositive, whereas in that of the trigonal axis it s always negative. (3) The magnetic expansion urves for crystals of intermediate orientations re determined by the resultant of the above xpansion and contraction. (4) The magnetic xpansion in ordinary polycrystalline iron is a ifferential effect of the expansions and contracions of the numerous crystals of random orientaions. The work of these Japanese investigators as therefore demonstrated that hysteresis loss nd permeability are functions of the number of rystals in unit volume, and that magnetic exansion is a directional property of the crystals.

A similar research was carried out by Gerlach.[28] 'he results obtained were in substantial agreeent with those of Honda and his co-workers, nd the magnetic properties of single crystals ere shown to be definitely directional. It was ound that the initial permeability is greater in ie tetragonal than in the digonal direction, and iat saturation in the tetragonal direction occurs t a lower magnetic force than in the digonal irection. This investigator found that slight eformation produces considerable changes in iagnetic properties, and attributed the small iscrepancies between his results and Honda's o the existence in the latter of slight mechanical sturbances. The effect of these was most arked in the curves connecting field intensity and tensity of magnetisation.

The longitudinal magneto-resistance effect in ngle crystals of iron has been investigated by 'ebster.[29] He measured the change of resistance a longitudinal magnetic field for three different ientations of iron crystals. He found that for the tragonal direction there is no change in resistance a longitudinal magnetic field, whereas in the igonal and digonal directions the electrical restance begins to alter when a magnetic intensity about 800 c.g.s. units is attained.

Various magnetic properties of nickel crystals ıve also been determined, principally by Kaya. ıis investigator found that up to an intensity of agnetisation of 205 c.g.s. units, nickel crystals e isotropic, but that above this intensity the magnetisation varies for different directions of the applied field. Trigonal, digonal, and tetragonal axes are in decreasing order of magnetisability, which is the reverse of the order found for iron. The same investigator measured the change in electrical resistance of single nickel crystals in longitudinal and transverse magnetic field. In a longitudinal magnetic field, every direction of the axes shows an increase in resistance, the amount of increase being in the decreasing order [111], [110], and [100]. These results differ from those obtained by Webster, who found no increase in resistance for the [100] direction in iron crystals.

The magnetic expansion of single crystals of nickel has been measured by Masiyama. He found that in a longitudinal field the magnetic expansion is always negative for all fields and in all directions, and that the absolute amount of contraction decreases in the order of the direction [100], [110], [111]. The transverse effect was found to be the opposite of the longitudinal.

Electrical Conductivity.

A considerable amount of work has been done on the electrical conductivity of single crystals, and in general it has been found that for those belonging to the cubic system the resistivity is the same in all directions, while for those in other systems the greatest resistivity is found to be in the direction of the planes on which slip most easily occurs.

In comparing the difference between single crystal and polycrystalline bars of zinc with respect to thermal and electrical conductivity over the range -250° C. to $+100^\circ$ C., Lewis and Bidwell found that: (1) The thermal conductivity decreases smoothly, but not linearly with rise in temperature. (2) Single crystals of zinc, measured in the direction of the basal plane, have 11-18 per cent better thermal conductivity at 0° C. than polycrystalline bars. (3) Single crystals of zinc have 20-30 per cent less electrical conductivity at 0° C. than polycrystalline bars.

Bridgman has conducted numerous investigations on the conductivity and thermal electromotive force of crystals of low symmetry. In 1926 he published a paper on the thermal conductivity and thermal e.m.f.[30] of single crystals of zinc, bismuth, cadmium, and tin. Both properties were shown to vary with the orientation of the crystals, and this variation was particularly marked in the case of the thermal e.m.f. Using improved methods of casting single crystals which permitted the production of a wide range of

orientations and a more accurate means of measuring the thermal e.m.f. and resistance, he was able in 1928[31] to demonstrate more clearly the relation between these properties and the orientations of the crystals. He found that the thermal e.m.f. was a linear function of $\cos^2$, where θ is the angle between the axis of the crystal and the length of the rod. This verifies the relation of Kelvin and Voigt, about which Bridgman, on the basis of his previous work, had expressed doubt.

Density.

It has been found that the density of iron single crystals is 0·037 per cent greater than that of the polycrystalline material: that that of nickel single crystals is 0·110 per cent greater than that of the polycrystalline material; and that the density of aluminium single crystals is 0·034 per cent greater than that of the polycrystalline materials.[32]

Electromotive Characteristics.

Measurements of the electrode potential of single crystals of zinc have been carried out at Yenching University, Peking, by Paul A. Anderson.[33] The results indicate that the primary cleavage plane of zinc—the basal pinacoid—yields constant and reproducible values of the electrode potential, and that this value is the same as that obtained from electrolytically deposited crystal conglomerates. This result seems to indicate that in the electrolytically deposited conglomerate the crystals have a random orientation, and that the basal pinacoid plane has the maximum electrode potential of all planes. Attempts to prepare zinc crystals with naturally developed secondary faces proved unsuccessful, and measurements of electrode potential were made on artificially prepared surfaces. The results obtained in this way indicated a qualitatively regular decrease of potential with increase in the angle between the plane under consideration and the primary cleavage plane.

An investigation of the relation between electrode potential and the density of the atom on different planes of zinc crystals has also been carried out in the University of Latvia.[34] The results obtained in this investigation did not agree with those already mentioned, and no difference could be found in the potentials of different, artificially prepared planes.

It is very probable that the electromotive characteristics of a metal vary with the orientation of the surface on which they are measured, but the variation in these characteristics is difficult to measure on artificially prepared surfaces. The Latvian investigators attributed the negative results obtained to this fact. They pointed out that polishing, filing, or rubbing with emery disintegrates the crystallographic planes and the resulting structure is indefinite and shows no differences of potential, whereas etching with dilute acids attacks the surface very unevenly, and no definite plane results. It is probable that the results obtained by Anderson were qualitatively correct, but definite confirmation of these must await measurements of the electrode potential of naturally developed faces.

It is clear from the foregoing results, and others which it has not been possible to include, that both the mechanical and physical properties of the single metal crystal are, in the majority of cases, directional. This fact is more strikingly illustrated in the mechanical tests because the single crystal test-pieces undergo distortion and assume new and striking forms. In both categories, however, the properties of the single crystal differ from those of the crystal aggregate, depending upon its particular orientation. Single crystal alloys have been investigated to a less extent, but in so far as evidence is available, it indicates that the same holds for them. The scientific investigation of metals in the future will have to take into account both the monocrystalline and the polycrystalline states, and the variations in any particular property which may be secured by varying the orientation of the crystal. This will involve the controlled production of single crystals in particular orientations, a field of investigation which is only just being opened up.

Knowledge of the mechanics and physics of the metal crystal is only in its infancy. From the point of view of pure science, it is the single metal crystal which will have to be investigated in the first instance. That of the crystal aggregate of any particular average size should follow at a later stage. Such knowledge will form the basis of the scientific manufacture of metals and alloys possessing properties which can be specified with accuracy and certainty.

came in from outside. Kolhörster himself had computed $\mu = 0.55$ as reported in Meyer and von Schweidler's book, p. 606. Bowen and I had at that time no other observations to guide us, nor did any more appear for more than a year thereafter. Since all conceivable sources of error would make our results come out too high, the fact that our balloons came down with a discharge of approximately one-fourth the expected value was definite unambiguous proof to us that a radiation of such a coefficient as we had assumed in our computations did not come in from outside, that rather, if the observed effects were due to extra-terrestrial rays at all, these rays had to be very much harder than had been supposed, and we so reported at the meeting of the National Academy of Sciences held in Washington in April 1922. In doing so, we did not reflect in any way upon our predecessors. We obviously had no choice but to report our findings. Indeed, we had so much confidence in Hess and Kolhörster as observers that we felt that the very large discrepancy between their results up to 9 km. and ours up to 15·5 km. cast so serious doubts upon the adequacy of hypothesis No. 1 that we spent a year preparing new experiments on absorption coefficients of the penetrating rays to enable us to differentiate sharply between hypothesis No. 1 and hypothesis No. 2, since No. 3 had already been definitely eliminated by Gockel's experiments, now checked by Hess, Kolhorster, and ourselves.

It was eighteen months later, after Dr. Otis and I had made our absorption experiments with lead and water on top of Pike's Peak, that we found that these discrepancies between Bowen and Millikan's and Hess and Kolhörster's balloon findings, discrepancies which had caused us so much concern and raised so much doubt about the interpretation of the penetrating rays, had been removed by Dr. Kolhorster's 1923 work in the Alps, which yielded $\mu/P = 0.25$ per metre of water, a result which is in substantial agreement with our sounding balloon data, as we have definitely shown.[22] The difference in the ionisation to be expected at the top of the atmosphere between $\mu = 0.25$ and $\mu = 0.57$ is enormous, and the sounding balloon flights were the first to reveal the untenableness of the last figure. I believe that all recent work is in substantial agreement with the first figure. We have never thought it necessary to contradict or to answer at all the critiques of our sounding balloon experiments, for the simple reason that the data obtained in these balloon flights appear to speak for themselves since the result yielded is now generally accepted.

Our critics charge Dr. Cameron and myself with misrepresentation because we said that "up to this time the increasing rate of discharge was the sole phenomena upon which the hypothesis of rays of cosmic origin rested", *but they insert the year* 1925 *instead of the correct year*, 1922, and then quote Kolhörster's 1923 data to show our error. The table given in Meyer and v. Schweidler's "Radioactivitat" (1927), p. 606, actually records no absorption coefficient obtained up to 1922 in any way except from measurements in air.

The only remaining point of criticism of our article is in our statement that our observations at great depths in the water of high-altitude snow-fed lakes, definitely shown by long tests to be free from radioactive impurities, represent the first time that the zero of an electroscope had been definitely determined. Our critics think that Bergwitz succeeded in doing the same thing when he in 1915 took an unsealed electroscope into a salt mine and *assumed* the non-existence of any radiations from radioactive impurities in the surroundings. For the purpose of assuredly eliminating completely both local and cosmic radiations, it scarcely seems to us that Bergwitz's procedure in 1915 can be called a trustworthy determination of the zero of an electroscope. In an instrument of a litre capacity containing air at atmospheric pressure, his reading was 8 ions at the surface, 4 ions in the salt mine. With an instrument of the same volume and pressure our reading at the surface is 7 ions, under 150 feet of water it is 1·6 ions. The larger difference in our case probably means that we are better screened from local effects. In any case, unless careful tests for such screening were made, we doubt if Dr. Bergwitz himself would call it a zero determination. However, we are very glad to be informed of his experiments, which we had in fact overlooked.

The worst case of misunderstanding and misstatement that I have seen, however, is met with, not in connexion with articles on cosmic rays, though probably due to misconceptions engendered by these articles, but in a review of a short article I wrote by request for the American Philosophical Society on "The Last Fifteen Years of Physics"[5] which is abstracted in the *Physikalische Berichte*, April, vol. 8, p. 465, No. 7; 1927. In so short a review as I had to give here of so huge a field, it is of course impossible that any two people would select precisely the same group of advances to emphasise, but if there was any national bias in the list selected I was completely unconscious of it. Furthermore, such bias was not noticed by the best informed European physicist of my acquaintance, who actually viséd this particular article before it went to press. The reviewer's misunderstanding and misrepresentation of the article is presumably due to preceding misconceptions, and barely possibly in part to the fact that in this necessarily very sketchy enumeration of a number of important advances, I repeatedly inserted references to my book on "The Electron" or to my more extended articles like those on cosmic rays, merely for the sake of giving the reader opportunity to look up, if he wished, my more complete discussion of the advances under consideration. The reviewer appears to have taken these references, without looking them up, as claims of discovery by me, whereas they actually contain merely the history of the advances, altogether objectively presented. *Actually no such claims as the reviewer asserts are either made or implied.* Again, therefore, I beg the reader to read the article in question before he draws any conclusion about it.

Returning to the main question here under discussion, there can be no doubt whatever about the fact that every country tends to get its own contributions out of their true perspective. Having been brought up, scientifically, largely on German books, I well recall my surprise, when I had opportunity to spend a few months of study in Paris and Cambridge, to find how badly I had underrated French and English contributions to the development of physics, an error which a few months of study in these centres was well calculated in its turn to correct. It is in this correcting of perspective that the great value of foreign study lies.

We Americans have in the past made so few contributions ourselves, and have been brought up so completely on foreign books, and in foreign schools, that we have been in a particularly favoured position for appraising the contributions of other countries, without being too much impressed with our own scientific importance, since everybody has recognised the fact that we had none. That we, too, are beginning to be charged with a nationalistic bias in science is perhaps merely an indication that some contributions are actually beginning to come from this side of the water.

As international contacts in science increase, and they are now doing so more rapidly than ever before, it is not too much to expect that science will very soon become more completely objective that it has been heretofore. There will be two signs of the approach of that hoped-for day: first, a decreasing amount of international claiming of priorities; secondly, and even more important, a decreasing amount of suspicion of nationalistic motives and of making of unwarranted charges of prejudice in the presentation of work.

The Welland Ship Canal.

THE opening on July 1 of the reconstructed Welland Ship Canal between Lake Erie and Lake Ontario marks an important stage in the developments of the North American waterways which will ultimately enable large vessels to pass between the Great Lakes and the Atlantic Ocean. Lakes Superior, Michigan, Huron, Erie, and Ontario constitute the greatest lake system in the world, and owing to their geographical position and the rapid exploitation of the vast natural resources of the North American continent, the traffic on them, already of enormous proportions, is steadily increasing. Ore, coal, and grain form the greater part of the cargoes carried, and the vessels employed are especially constructed for the quick stowage and discharge of cargo. Many of them, too, are of very large dimensions, there being more than 300 vessels of 600 feet or more in length. In 1926 one vessel carried a single cargo of 15,900 tons, while 12,000 tons of ore have been loaded in about a quarter of an hour. Owing to climatic conditions traffic is only possible for seven or eight months in the year, but in this time a greater tonnage passes between Lake Superior and Lake Huron than passes through the Suez Canal, the Panama Canal, and the Manchester Ship Canal combined.

Between Lake Superior and the Atlantic, however, there are three natural barriers to shipping, the first between Lake Superior and Lake Huron which has led to the building of great locks on both the Canadian and United States sides; the second between Lake Erie and Lake Ontario, formed by the Niagara escarpment across which the Welland Canal runs, while the third lies in the unnavigable stretches of the St. Lawrence below Lake Ontario, to avoid which the St. Lawrence Canal was constructed. This canal at present only admits of the passage of vessels about 260 ft. in length, but its enlargement is already being discussed. One interesting feature of the traffic through the canals is that ships, whether Canadian or American, pass through free of tolls.

The Welland Canal is situated a few miles to the west of the River Niagara and runs practically north and south from Port Weller on Lake Ontario to Port Colborne on Lake Erie, the distance being about 25 miles. Between the lakes there is a difference of level of 325 ft. The first Welland Canal was built a hundred years ago with forty small wooden locks admitting the passage of vessels of 7½ ft. draught. In the 'forties of last century the canal was reconstructed with twenty-seven locks 120 ft. long, 26 ft. wide, and 8½ ft. of water. It was again reconstructed in the 'seventies with locks 270 ft. in length, 45 ft. beam, and 14 ft. of water, and the traffic by 1904 had grown to 620,000 tons and by 1914 to 4,000,000 tons per annum. By then the decision to convert it into a ship canal of the first order had already been made, and the canal to-day has but eight locks, but these are each 820 ft. in length, 80 ft. wide, and with 30 ft. of water over the sills.

Needless to say, the present reconstruction of the canal has involved engineering works of the first magnitude. Embankments, breakwaters, harbours, storage basins, spillways, weirs, bridges have all had to be built, while the most important

feature of the canal is the flight of three twin locks, Nos. 4, 5, 6, which have been built at Thorold and constitute a structure 4100 ft. in length and more than 300 ft. wide. The three locks together have a total lift of 139½ ft., being 54½ ft. greater than the lift of the three locks at Gatun on the Panama Canal. The locks are not so large as those in the Panama Canal, which are 1000 ft. long and 110 ft. wide, but the lift for such a work is unprecedented. The walls for the greater part are formed of reinforced concrete monoliths 60 ft. in length.

During the past year a fully illustrated account of the canal and its construction has been published in *Engineering*, and the articles have included descriptions of the great excavating machines, the travelling forms and the concreting plants with the aid of which the massive walls have been built. In the Panama Canal ships are towed through by electric locomotives, but in the Welland Canal they will proceed under their own power. Every precaution, however, has been taken against accident; the twin locks have double gates, and wire rope hawsers guard the entrances to the locks. The gates themselves are 82 ft. high, 48 ft. wide, and 5 ft. thick, each weighing 480 tons. For the control of the gates and the working of the numerous large sluices and valves throughout the system, electrical machinery has been installed and current for this will next year be available from a power station placed at the foot of the three twin locks. This will contain three 5000 h.p. hydraulic turbines working under a head of 186 feet. The whole of this great work has been carried out by various contractors working under the direction of the Department of Railways and Canals of the Dominion with Mr. Alex. J. Grant as Engineer-in-Charge.

News and Views.

THE discourse by Sir Harold Carpenter which we publish to-day as a special supplement provides a very complete survey of the important results which have been obtained by the study of single crystals of metals. Whilst ordinary metals consist of a large number of crystals with their axes directed more or less at random, means have been devised for producing specimens, large enough for the tests usually applied by the engineer to metallic specimens, but consisting of a single individual. An extensive field has thus been opened up for the study of the properties of solids. The use of single crystals eliminates one very obscure factor, the existence of boundaries of unknown properties between the crystals, and also, by limiting the directions in which slip can occur under the influence of stress, greatly simplifies the geometrical conditions of a mechanical test. The study of the electrical, and especially of the magnetic, properties is correspondingly simplified. It becomes possible to compare the properties of metals with those of ionic crystals, such as rock salt, which have so far proved most amenable to theoretical treatment. The work on metallic single crystals is thus certain to throw much light on a problem of the greatest interest to the engineer as well as to the physicist—that of the cohesion of solids.

THE methods adopted by the crystallographer for growing perfect crystals of salts fail completely when applied to metals, and it has been necessary to devise new methods. For readily fusible metals, the slow solidification of the molten metal in a tube cooled from one end has proved most successful, but other means of attaining the same end have proved their value. The production of very large crystals in homogeneous metals by suitable annealing after critical strain, due originally to Sir Harold Carpenter and extensively applied, especially by him and Miss Elam, has furnished the material for the detailed study of the deformation of single crystals, in which the X-ray method of examination has rendered such valuable services. Lastly, the ingenious method of the Dutch investigators, depending on the decomposition of the vapours of metallic iodides by heat, has made available crystals of some of the most refractory of the metals. There still remain many unsolved problems, and there is still no general agreement as to the nature of the process of hardening by cold-working, but Sir Harold Carpenter clearly indicates the immense advances in the study of metals made possible by the new technique.

THE Institute of Physics a short time ago appointed a committee to inquire into the possibility of drawing up a catalogue of apparatus which had been used in the course of investigations leading to important discoveries. At the request of the committee the Institute is now making a general appeal to all who have charge of historic apparatus. The appeal, which is signed by Dr. W. H. Eccles, Sir F. W. Dyson, Sir W. H. Bragg, Sir C. A. Parsons, Sir J. J. Thomson, Sir R. T. Glazebrook, and Sir H. G. Lyons, is made with the object of obtaining information as to the existence of apparatus and the researches it was used in, so that students of the history of science may be able to visit, identify, and study it. It is also suggested that the committee could possibly assist the owners, if they so desire, to place the apparatus where it could be permanently secured to the nation. In such institutions as the Science Museum, the Conservatoire des Arts et Métiers, the Deutsches Museum, and the Smithsonian Institution, England, France, Germany, and America already possess extensive collections of great value, and there are probably few observatories, laboratories, or scientific societies which do not own some historic apparatus, while other instruments are in private hands. Practically every private collection, however, is ultimately dispersed, and the compilation of such a catalogue as that now being formed might lead to the more historic apparatus becoming the nation's property. As with pictures and other works of art, the selective principle should be applied, and a

joint committee of the Institute of Physics and kindred societies would be a suitable body to act in an advisory capacity.

IN the past, wars, riots, and fires have been the cause of the destruction of much valuable apparatus. Gilbert's collection, which he bequeathed to the Royal College of Physicians, was lost in the Great Fire of London: Hevelius lost both observatory and instruments by a fire at Danzig in 1679; the great fire at Copenhagen in 1728 led to the destruction of Römer's telescopes, and the first observatory at St. Petersburg was burnt down in 1747. One of the most deplorable of all losses was occasioned by the fire at the Volta Centenary Exhibition at Como in 1900, when Volta's original piles and cells, etc., were lost. Wars have been no less destructive than fires. The manuscripts of Thomas Harriott, astronomer and mathematician, disappeared during the Civil War: Gregory Saint-Vincent, the seventeenth century geometer, lost all in the siege of Prague: Chladni lost some of his acoustical apparatus during the Napoleonic Wars, while Regnault, after the occupation of Paris by the Germans, returned to his laboratory at Sèvres to find his standard apparatus and the results of his great researches on the expansion of gases ruined. The destruction of Priestley's library and apparatus occurred during the Birmingham Riots of 1791. How important instruments may disappear unrecorded is shown by the case of Sturgeon's electrical apparatus. In 1825 the Royal Society of Arts recorded the award of a medal and thirty guineas to Sturgeon for the gift of his electromagnetic apparatus, but this, including the first electromagnet ever made, has unfortunately long since disappeared. Such, it may be hoped, will not happen to any important collection in the future, and we feel that the Institute of Physics is doing a public service in obtaining records which should go far to prevent such losses from happening.

ON June 14 a large meeting of university professors, academicians, and scientific men met in the great hall of the Palace of the Apostolic Chancery in Rome in commemoration of the third centenary of the death of Prince Federico Cesi, the founder of the Accademia dei Lincei. After introductory remarks by the president, Prof. Giuseppe Gianfranceschi, Prof. Antonino Anila recounted how the idea came to Cesi of bringing together all scholars of that time the first serious attempt to organise human knowledge recorded in history. This academic activity was to have its centre in Rome, but was to embrace the whole world then known. From this suggestion was born the Accademia dei Lincei, so named from the power attributed to the lynx (*la lince*) of seeing into the depths of things. The most illustrious scientific men of the day supported the project, and Galileo was desirous of becoming a member of the Academy. Prof. Anila emphasised the fact that, so far as his astronomical discoveries went, Galileo received nothing but help from the Church, the opposition to him being based on his persistence in his own special interpretation of the scriptures. Cesi himself made a large number of discoveries bearing on the structure, functions, and classification of plants, being the first to utilise the microscope in such investigations; and in addition he made noteworthy contributions to mineralogical and zoological knowledge. Prof. Anila was followed by the Rev. Prof. Agostino Gemelli, who traced the developments taking place after the death of Cesi, and indicated the relationships between the original academy and the Accademia Pontificia dei Nuovi Lincei and the Reale Accademia dei Lincei of the present day. Prof. Gemelli also contested the view, expressed by certain historians, that the activities of the academy were often restricted as the result of clerical antagonism, especially that of the Jesuits, or of lack of papal support.

THE appointment of a Committee to consider and report on the training of candidates and probationers for appointment as forest officers in the government service was announced in NATURE of June 21. In directing attention to this Committee, the Secretary of State for the Colonies points out that the proper conservation and development of the forests of the British Empire is a problem which has been attracting increasing interest of recent years and is one of great national importance. The Colonial Office is responsible for the management of about one-third of the total forest area of the Empire. It is recognised that the Colonial Forestry Services have been very weak in numbers, whilst, owing to changes or possible changes in the demands for different kinds of timber, it is becoming a matter of urgent importance to explore the possibilities of making fuller uses of the tropical hardwood forests of the Empire. It is considered that a careful inquiry may show that there are some directions in which greater facilities may be made available for the training of future forest officers. To undertake such an inquiry is the *raison d'être* for the appointment of the Committee.

JOHANN KEPLER is recognised as one of the founders of modern astronomy, and his discoveries are known to every student of physical science. He was to Germany what Galileo was to Italy and Newton to England, and it is therefore with interest we learn that arrangements are being made to commemorate the tercentenary of his death, which falls on Nov. 15 of this year. Kepler died in 1630, in the midst of the Thirty Years' War, and was buried in the churchyard at Ratisbon, but the churchyard was practically destroyed in the desperate struggles of the time and the site of his grave is no longer known. In 1803, however, the venerable Prince Primate Dalberg, known for his love of the fine arts, erected a cenotaph at Ratisbon to Kepler's memory, and the commemoration proceedings will commence on Sept. 24 before this memorial with an address by Dr. von Dyck, of the Munich Technical High School. The same evening a meeting of the Society of History and the Society of Natural History will be held, and on the following day Prof. Bauschinger of Leipzig will deliver an address in the old Reichssaal at Ratisbon. The proceedings will be brought to a close with an act of homage before the bust of Kepler in the Walhalla near the city.

MANY places in Germany beside Ratisbon are connected with the memory of Kepler. Born in the little town of Weilderstadt in Würtemberg, Kepler

attended school at Maulbronn, was a student at the University of Tübingen, and in 1594 became a professor of astronomy at Gratz. At Prague he lived for a short time with Tycho Brahe, and he afterwards held professorships at Linz, Rostock, and at Sagan in Silesia. There was nothing in his upbringing or surroundings to stimulate Kepler's interest in science and from his earliest days he had a struggle against misfortune. A sickly child of well-born but indigent parents, he suffered more than once from severe illness, he had the unhappy experience of seeing his parents separate, while after his own marriage, domestic affliction and pecuniary difficulties dogged his footsteps. Even after receiving the appointment of imperial mathematician to the Emperor Rudolph, his salary was often sadly in arrears, and it was while attempting to obtain some money that he died at Ratisbon. Yet amid all his difficulties he was able to publish no fewer than thirty separate works, and he left behind twenty-two volumes of manuscripts. It was apparently from the lectures of Moestlin that he learnt of the revolutionary views of Copernicus, while it was from the long series of observations of Tycho Brahe that he obtained the material which enabled him to search out and enunciate the laws of planetary motion. Beside the memorial at Ratisbon, there is a monument to Kepler at Weilderstadt, a description of which was given in NATURE of July 21, 1870, at the time it was unveiled.

AN industry the breeding of game birds which is well established in Great Britain, though on a small scale, is attracting greater attention in the United States of America. Already some of the largest and most productive game farms in the world have been developed there, and the supply is met by an ever-increasing demand. This has largely to do with the development of the sport of shooting in the States, for most of the game-birds and their eggs are used for restocking State game departments and the 'shootings' of sportsmen's clubs. But in addition the demand for stock for propagating, and the needs of bird fanciers and zoological gardens, are so great that it is seldom necessary to dispose of the birds for food. For the guidance of game-bird breeders the U.S. Department of Agriculture has issued two *Farmers' Bulletins* (Nos. 1612 and 1613) on the propagation of aquatic game birds and of upland game birds, from which may be obtained concise and useful hints on the most up-to-date methods employed in the industry.

THAT alligators should have an economic importance so great as to merit the establishment of alligator reserves and farms will surprise many readers, but it is perhaps more astonishing to learn that the use of alligator hides for one purpose or another has been in vogue in the United States since about 1800. Nowadays the industry concerns itself with the manufacture of trunks, travelling bags, purses, pocket-books, shoes, and miscellaneous novelties, and the result has been a decline in the numbers of alligators which, in some places, threatens extinction. In the beginning of this century the output of the United States tanneries was about 280,000 skins annually, valued at 420,000 dollars, but during the past few years the number cannot have exceeded 50,000 a year, prices ranging from 35 cents for a 3-foot skin to 3 or 4 dollars for a 7-foot skin. Accordingly, the alligator, once denounced, has come to be protected by local laws which enforce a close season, a licence for trappers, and have even created a State Alligator Reservation in Florida. This and much information about the habits, the hunting, and the food of *Alligator mississipiensis* is contained in *Technical Bulletin*, No. 147, of the U.S. Department of Agriculture.

THE fundamental scientific research work which is being carried out under the Clothworkers' Research Scheme in the University of Leeds is year by year becoming more important and receiving more extensive recognition. Perhaps no better indication of the value which is being placed upon this work in scientific circles could be given than that accorded by the Royal Society, which has recently made a grant of £200 for apparatus to facilitate the X-ray work on textile fibres upon which Mr. W. T. Astbury is engaged. This work, along with the physico-chemical work under Mr. J. B. Speakman, is gradually clearing up the complex problem of the structure of the wool fibre, and in the near future it is probable that, knowing what wool really is, better control of the manufacturing processes may be ensured. Thus, the wisdom of running, side by side, fundamental scientific research and textile technology is becoming more and more justified.

THE Department of Zoology of the British Museum (Natural History) has received from Col. F. Wall a collection of more than a thousand skulls and skeletal preparations of Indian snakes, which is by far the most complete collection of its kind ever assembled. The Department of Geology has acquired by purchase a skeleton of the short-legged rhinoceros *Teleoceras fossiger* from the Pliocene of Kansas, U.S.A. An important addition to the collection of meteorites is a fine mass of meteoric iron weighing 299 lb. and forming a complete individual mass, from South-West Africa. This was one of some thirty masses weighing about ten tons displayed in the Public Garden at Windhoek. These had been collected from the desert in the neighbourhood of Gibeon in Great Namaqualand, where in prehistoric times there must have been a terrific shower of enormous masses of iron. Another valuable donation to the Department of Mineralogy is a magnificent group of large crystals of melanterite (iron vitriol) found in ancient workings in the Skouriotissa mine, Cyprus. Mr. R. Crawshay has presented to the Department of Botany 167 crayon drawings of *Russula*. *Russula* is a genus of Agaricaceae (toadstools) which is characterised by the bright colours of its cap and the clearly cut, paper-like gills. Mr. Crawshay has just published a book, "Spore Ornamentation of the Russulas", in which a classification of the species on the basis of the spore characters has been fully worked out. In this work it was impossible to publish drawings of the fungi which were examined, and consequently the original drawings have an additional value.

As a memorial to the late Sir George Beilby, the distinguished chemical engineer, who died in 1924, a

fund was collected in 1926 from the interest on which, at the discretion of the administrators, awards are to be made from time to time to British investigators in science, to mark appreciation of distinguished original work carried out over a number of years, preference being given to investigations relating to the special interests of Sir George Beilby, including problems connected with fuel economy, chemical engineering, and metallurgy. The administrators of the fund have announced the award of £250 each to Dr. Guy D. Bengough, of the Chemical Research Laboratory, Teddington, and Mr. Ulick R. Evans, of Cambridge. The administrators of the fund are the presidents, treasurers, and secretaries of the Institute of Chemistry, the Society of Chemical Industry, and the Institute of Metals.

THE thirty-ninth annual report of the Council of The Institution of Mining and Metallurgy records the following awards which were presented at the annual general meeting on June 26. The gold medal of the Institution to Sir Thomas H. Holland, in recognition of his distinguished services to geological science and to the mineral industries during his tenure of high public appointments—notably those of director of the Geological Survey of India and of rector of the Imperial College of Science and Technology —and of his researches and publications upon the mineral resources of the British Empire and their relationship and national and international problems. 'The Consolidated Gold Fields of South Africa, Ltd.' premium of forty guineas to J. B. Richardson, for his paper on "The Importance of Recovered or 'Secondary' Tin". The 'William Frecheville' Student's Prize of ten guineas to A. Bray, for his "Notes on the Banket Reefs of the Gold Coast Colony". The 'Arthur S. Dwight' post-graduate travelling grant of two hundred guineas to W. D. Jones. In accordance with the conditions of the grant, Mr. Jones proceeded to the United States in October, where he spent about three months in the study of metallurgical plants and in making personal contacts with operating men. Since his return to England he has submitted to the Council an exhaustive report of his visit. A special grant of £50 from the 'Post-Graduate Grants Fund' of the Institution to S. R. B. Cooke, to enable him to proceed to British Columbia to gain practical experience. The grant was made on the nomination of Prof. James Park, dean of the faculty of mining and economic geology of the University of Otago, New Zealand.

THE University of Freiburg has conferred the honorary degree of doctor of natural philosophy upon Dr. F. W. Aston in recognition of his work on isotopes and other subjects.

AN interesting innovation has been introduced into the advance proofs of papers recently circulated by the Physical Society. Wherever a mathematical symbol occurs for the first time, or is defined, the symbol is noted in the margin. Thus any reader who wishes to find quickly what the symbol denotes has only to run his eye up the margin, a far more rapid process than is sometimes necessary in scientific papers.

A PROVISIONAL programme of the fourth World's Poultry Congress, to be held at the Crystal Palace on July 22–30, has just been issued. The congress is being organised by the Ministry of Agriculture and Fisheries, in conjunction with the Department of Agriculture for Scotland and the Ministry of Agriculture for Northern Ireland, and fifty-six countries, ranging alphabetically from Argentina to Yugo-Slavia, are taking part in it. The programme contains a short account of the objects of the congress, a list, with many photographs, of the personnel of the national committees, and a diary of the daily sessions. The papers to be read at the morning meetings are extraordinarily numerous and comprehensive, but the provision of many afternoon and evening entertainments and a post-congress tour suggest that there is no danger of making Jack and Jill dull children. The fee for full membership of the congress is £2 : 2s. for each member from the United Kingdom, and half that amount for wives and relatives of members.

A CORRESPONDENT directs our attention to an experiment described in a recently published school book on chemistry, in which metallic mercury is to be heated in a crucible. This would have the effect of volatilising the mercury, and if the experiment were performed by a number of pupils in a school laboratory the effects might be very serious. Teachers are reminded that the poisonous effects of mercury vapour were recently emphasised by Prof. Stock, and they are warned that such experiments as that just described should never be carried out in school laboratories.

MESSRS. H. K. Lewis and Co., Ltd., 136 Gower Street, W.C.1, have just issued a handy list of current works on engineering—electrical, civil, and mechanical —which many readers should find serviceable.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: A director of education for the County Borough of Middlesbrough—The Town Clerk, Municipal Buildings, Middlesbrough (July 8). An assistant lecturer in agricultural engineering in the University of Leeds —The Registrar, The University, Leeds (July 12). An assistant instructor in dairying at the British Dairy Institute—The Secretary, British Dairy Institute, The University, Reading (July 12). An agricultural education officer under the Isle of Wight County Council Education Committee—The Director of Education, County Hall, Newport, I.W. (July [illegible]). A bacteriologist at the Government Lymph Establishment, Hendon—The Director of Establishments, Ministry of Health, Whitehall, S.W.1 (July 14). An assistant lecturer in geography in the University of Leeds—The Registrar, The University, Leeds (July [illegible]). An assistant lecturer in organic chemistry at the University College of North Wales, Bangor—The Registrar, University College of North Wales, Ban[illegible]

(July 14). Temporary assistant chemists in the Government Laboratory—The Government Chemist, Clement's Inn Passage, W.C.2 (July 19). An assistant works manager of the Metal and Steel Factory, Ishapore, India—The Secretary, Military Department, India Office, S.W.1 (July 19). Three research fellows in the Department of Glass Technology of the University of Sheffield—The Registrar, The University, Sheffield (July 19). An assistant plant pathologist under the Department of Agriculture and Forests of the Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1 (July 21). An inspector of agriculture under the Department of Agriculture and Forests, Sudan Government—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, S.W.1 (July 21). An assistant lecturer in the Department of Zoology of King's College, London—The Secretary, King's College, Strand, W.C.2 (July 21). A research physicist in the Department of Glass Technology of the University of Sheffield—The Registrar, The University, Sheffield (July 21). A lecturer in botany and assistant lecturers in pharmacy and chemistry at Robert Gordon's Colleges, Aberdeen—The Secretary and Registrar, Robert Gordon's Colleges, Aberdeen (July 23). A research demonstrator in the division of biochemistry of the London School of Hygiene and Tropical Medicine—The Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1 (July 24). A student probationer (zoologist, botanist, or physiologist) at the Marine Biological Laboratory, Plymouth—The Director, Marine Biological Laboratory, Plymouth (July 30). A professor of education in the Rhodes University College, University of South Africa—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (July 31). An assistant professor of anatomy in the University of Manitoba—The Dean of the Faculty of Medicine, Medical College, Winnipeg, Canada (Aug. 8). A woman demonstrator and assistant lecturer in chemistry at Royal Holloway College—The Principal, Royal Holloway College, Englefield Green, Surrey (Aug. 30). A Smartt memorial scholar in the University of Cape Town, for research in subjects bearing upon agriculture—The High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (Sept. 30). A principal of the Aston Technical College—The Chief Education Officer, Education Office, Margaret Street, Birmingham (Sept. 30). Assistant lecturers and advisers in, respectively, agriculture, dairy husbandry, and horticulture, under the Bucks Agricultural Committee—The Agricultural Organiser, County Offices, Aylesbury. A lecturer in agricultural bacteriology in the University of Reading—The Registrar, The University, Reading.

ERRATUM.—June 28, vol. 125, page 967, col. 2, line 5 from end, for W. E. Beaton read W. E. Benton.

Our Astronomical Column.

Comets. Prof. H. E. Wood has computed the following parabolic orbit for Forbes's comet, 1930*e*:

T	1930 May 10·588 U.T.	
	321° 8′	1930·0
☊	278 13	1930·0
i	97 15	1930·0
log q	0·06183	

The following orbit of comet 1930*d* is by Dr. A. C. D. Crommelin from observations on May 2, 12, 22 (*B.A.A. Circ.* 95); it represents an observation of June 3 within a few seconds of arc:

T	1930 June 14·1826 U.T.	
ω	192° 18′ 18·92″	1930·0
☊	76 47 11·54	1930·0
i	17 24 34·76	1930·0
ϕ	42 21 25·37	
log a	0·4913883	
log q	0·0049406	
Period	5·458614 years.	

Mr. Blathwayte, of Johannesburg, who had not heard of the discovery of the comet, picked it up as a new comet on June 3; it is the second time that he has taken a known comet for a new one; he has also [dis]covered two comets that were really new. Comet [...] now too far south for European observers, but [will] be followed in the southern hemisphere for some [time]: it approached the earth within 4 million miles [early] in June; this seems to be the third closest approach on record. No news is yet to hand of [met]eors associated with the comet having been [...]

The Planet Pluto. Diligent search of old plates at Mount Wilson observatory has revealed four images that undoubtedly belong to Pluto on plates taken in December 1919 (*U.A.I. Circ.* No. 289). As they are situated within some 6 minutes of arc of positions calculated with the aid of the Uccle observation of January 1927, and as the mean daily motion (−5·14$^{sec.}$ in R.A. 6·8″ in decl.) is also in close accord with that calculated, the identity of the Uccle image with Pluto is also confirmed. The mean of the four positions was telegraphed as follows:

U.T. 1919.	R.A.	N.Decl. 1930·0.	Mag.
Dec. 29·0667	$6^h\ 29^m\ 3{\cdot}8^s$	19° 21′ 56″	19

There is probably some error in the telegraphed magnitude: it would be expected to be about 16.

U.A.I. Circ. 289 gives the following orbit of Pluto calculated by Nicholson and Mayall from observations in 1919 and 1930 (the 1927 position was not used).

T	1988 June 5·5 U.T.	
ω	111° 46′	1930·0.
☊	109 22	1930·0.
i	17 9	1930·0.
log a	1·60071.	
Period	251·86 years.	
e	0·2575.	

The perihelion distance is 29·61, which is slightly inside the orbit of Neptune. Owing to the high inclination, the two orbits do not approach each other within some four units. It will now be possible to make a trustworthy ephemeris of Pluto back to the beginning of the century, so that any other images that may be present on old plates should be identified with tolerable ease.

Research Items.

The Mound Builders of the Central Southern United States.—Mr. Warren K. Moorehead communicated to the Congress on Mid-Western Archæology held at St. Louis in 1929 a brief study of the mound-culture of the Mississippi Valley which has now been published in *Bull. 74 of the National Research Council of Washington.* Within the area of some twenty States several mound-building cultures are to be distinguished. The general custom of mound-building extends between the great plains and the Hudson. In a territory of 600 to 800 miles in extent mound art is highly developed, especially in certain places. An attempt to arrange the various mound cultures according to their status in cultural development suggests the following order: the Hopewell culture of the lower Scioto Valley, the Etowah culture of Northern Georgia and the Tennessee-Cumberland valleys, "Fort Ancient", the average village population of the Kanawha, Illinois, Arkansas, Wabash, Savannah, and other valleys, the Central Illinois Valley culture, and the Florida-South Georgia culture. As regards the origins of the Hopewell culture, it is suggested that a band of very early Algonkin reached or originated in eastern Iowa, one branch may have passed up into Wisconsin, the other proceeded eastward through Illinois and Indiana to Central Ohio, building mounds as they went. On reaching the Scioto Valley they became sedentary and attained the culmination of the Hopewell development. As regards the ultimate origin it is to be noted that Mrs. Nuttal has found seven detailed comparisons between early Toltec art and the Etowah culture.

Pleistocene Man in Ireland. Important work of excavation carried out by members of the Spelæological Society of the University of Bristol in caves in the South of Ireland is recorded in the *Proceedings* of the Society for the year 1929. The excavations, which were carried out in the summer of 1928, resulted in a discovery of no little importance for the history of early man in Ireland. They were undertaken with the view of obtaining material for comparison with results obtained by the Society in the Mendip caves—Aveline's Hole and others. Several caves in the neighbourhood of Dungarvan, Co. Waterford, were examined; but in one only, that of Kilgrany, was it found that any results were likely to be obtained. The area in which the caves are situated lies beyond that covered by the southern Irish moraine and was therefore uncovered in late Pleistocene times, when Ireland was probably joined to Britain. Excavation was carried to a depth of twelve feet from the original surface of the cave. In a stratification of several horizons, hearths were discovered in the second and fourth strata, and beneath the latter was stalagmite which showed an unbroken surface. Beneath a tufaceous portion of the stalagmite was a third hearth associated with a late Pleistocene fauna. In removing the tufaceous portion human remains were brought to light, which careful clearing revealed had been placed in a kneeling position with the left side resting against the wall of the cave. The body had then been surrounded and covered with stones which kept it in a kneeling and upright position. Prof. Fawcett, who has made a careful examination of the bones, pronounces them to be those of a male, 4 feet 7 inches in height. The skull is long, low, and with a pentagonal appearance from behind, recalling one of the Cro-Magnon features. On the whole, it is of Mediterranean type. Although no artefacts were found which would indicate a cultural horizon, there can be no question that the remains are the first of Pleiocene man to be discovered in Ireland.

Fungus Spores in Urine in Disease.—Some phenomena discussed in a paper by Toshio Ohue in the *Science Reports of the Tohoku Imperial University,* Sendai, Vol. 5, No. 1, as to the association of a fungus with a case of meningitis, are distinctly puzzling and deserve fuller elucidation. The spores of the fungus were found in the urine and cerebrospinal fluid of the patient; they were grown on in pure culture and the fungus is identified provisionally as *Alternaria tenuis* Nees. The fungus was also isolated from the dried persimmons which had been eaten by the patient a short time before his sudden illness. When cultures of this fungus were fed to animals it proved pathogenic to a marked degree to guinea-pigs, rabbits, and albino-rats, though in these animals the lungs are the organ chiefly affected, whilst in man the brain was attacked, the lungs showing little alteration. Comparison of the toxic action of cultures with spores and of ultra-filtrates of the bouillon cultures of the fungus suggested that the pathogenicity of the fungus is due primarily to the large spores (7-35 μ long by 7-12 μ broad). The mechanism by which the spores found their way to the urine is still in need of elucidation.

Iron Bacteria.—A very thorough study of these specialised micro-organisms appears to have been made by I. Turowska at various Polish stations, and is reported upon in the *Bulletin International de l'Académie Polonaise,* Cl. des Sc. Math. et Nat. No. 8-10, B.1, pp. 255-282, 1929. Organisms of the genera *Leptothrix, Gallionella,* and *Sideromonas* are studied. They require a certain amount of iron in the water, but more in sunlight, because the iron then tends to be precipitated more readily, less when the pH is near neutrality than at pH 6 for the same reason. Also, in saline waters they do not develop even when the iron content of the water is considerable, presumably because of the reaction of other salts present with the iron. The author attributes to the absence of solar radiation the frequent development of the iron bacteria in pipes even when the iron content of the water supply is low.

The Identification of Hair.—In an article entitled "Circumstantial Evidence from Hairs and Fibres" in the issue of *Chemistry and Industry* for May 30, Dr. C. Ainsworth Mitchell discusses the question of the identification of human hair and the hair of various animals, as well as the fibres of fabrics, from the point of view of legal evidence. The article contains many points of general biological interest as well as information of legal interest.

Inheritance in Fowls.—Frizzled fowls were known in Italy so early as the year 1600. They apparently came from the East, and in the eighteenth century were cited as occurring domesticated in southern Asia and the Philippines, Mauritius, and Mozambique. The feathers curl backwards; the barbs are also curled and later wear off, leaving the feather bare. Probably the skin was originally black. Mr. F. B. Hutt has made an investigation (*Jour. Genetics,* vol. 22, No. 1) of the current belief that frizzle fowls do not breed true and that the homozygous condition is lethal. His results show that the case is parallel to that of the blue Andalusians. Homozygous birds are viable, but they show the frizzled condition of the feathers in a more extreme form than the heterozygotes. The latter are preferred in the fancy, and so only such birds are usually found. When crossed with normally feathered fowls they gave a 1 : 1 ratio of normals and heterozygous frizzled. From this and other

evidence it is shown that the frizzled character is conditioned by a single non-sex-linked Mendelian factor, which is dominant, as are so many other factors in domestic breeds of fowls. In the same number Messrs. L. C. Dunn and Walter Landauer have shown from crosses of silky and white Leghorn fowls that the genes for dominant white, cerebral hernia and polyldactyly are located in the same linkage group or chromosome, the two former very near together and polydactyly some distance away, since it shows loose linkage with the other two.

Sardine Fishing in California. Mr. W. L. Scofield, of the Bureau of Commercial Fisheries, gives a detailed account of the methods used in the sardine fishery in "Sardine Fishing Methods at Monterey, California" (Division of Fish and Game of California. *Fish Bulletin* No. 19. Contribution No. 84 from the California State Fisheries Laboratory, March 1929.) The California Sardine *Sardinia cærulea* is very important commercially, occurring in shoals in enormous numbers. Great skill is needed in picking out those of the right size and much depends on the judgment of the captains of the boats. The schools are located by the luminescence produced by their movements. This can be seen readily on a dark night, and therefore the fishing is almost entirely confined to the night hours when the moon is not shining. A description of the Monterey fishery is given which can be used as a basis for judging future changes in the conduct of the industry. This includes fishing gear, fishing methods, notes on markets and canneries, besides general knowledge of the fishing-grounds. The bulletin is illustrated freely with diagrams and photographs, and embraces a large amount of useful information.

Copepods and Mites from the Philippines. Copepods from Central Luzon described by P. A. Chappuis (Harpacticoids), Friedrich Kiefer (Calanoids and Cyclopoids), and Hydracarina by C. Walter, include new species and sub-species (*Philippine Journal of Science*, February 1930). They are of interest because their region is almost unworked for these groups. Among the Harpacticoida new sub-species of *Nitocra platypus* and *Canthocamptus bidens* are recorded and a new species of *Diaptomus*, *D. sensibilis*. In the Cyclopoida a new variety or sub-species of *Mesocyclops leuckarti* was very abundant and also *Mesocyclops hyalinus*; a form belonging to the *Cyclops varicans* group was also present. All these are widely distributed species. Three mites are described, two of which are new species, *Limneria bakeri* and *Neumania flagellata*, whilst the third, represented by one ovigerous female, belongs to the Sumatran species *Neumania ambigua* Piersig.

Insects of Samoa and of South America.—Two publications of the British Museum (Natural History), more especially of interest to entomologists, have recently come to hand. Both are continuations of monographs which have already been alluded to on several occasions in our columns. The "Insects of Samoa" receives further contributions from Mr. J. R. Malloch, of the U.S. Bureau of Biological Survey, which form Part 6, Fasc. 5 of that publication. They deal with the Dipterous families Ortalidæ and Calliphoridæ. The "Diptera of Patagonia and South Chile" has reached Part 5, Fasc. 1, which is devoted to a description of flies of the family Dolichopodidæ from that region. Its author, Mr. M. C. Van Duzee, of Buffalo, U.S.A., describes a number of new genera and species of the family concerning which practically nothing was previously known from this part of South America. The two publications bear the date 1930 and, like all which emanate from the British Museum, are well printed and clearly illustrated.

Physiological Studies of the Swede.—Numerous studies of the sugar content of such 'root' crops as swedes, mangels, and beet have suggested that the sugar content is by no means uniformly distributed throughout the swollen storage organ. Mr. J. Caldwell has now carried the problem a stage farther in that, by numerous measurements and some simple experiments, he has shown that the increase in girth of the storage organ is different in north, south, east, and west directions, and that this different increase is closely correlated with the activity of the leaves above (*Proceedings Roy. Soc. of Edinburgh*, **50**, 130-141; 1929-30). Mr. Caldwell concludes, mainly as the result of observations of plants upon which all leaves on one quadrant of the shoot are removed, that this correlation is explained by the movement of food downwards into the swollen axis from the leaves above. It is desirable, however, to bear in mind the earlier observations of Jost which have shown the dependence of radial growth in the axis upon leaf development above, quite irrespective, apparently, of whether the leaf was sending food supplies downwards into a storage organ.

Anatomy of Grass Roots.—Dr. M. Henrici has some very interesting notes on this subject in *Science Bulletin*, No. 85, of the Department of Agriculture, South Africa, 1929. In the course of investigations near Vryburg, in British Bechuanaland, and in Ermelo in the eastern Transvaal, he had occasion to study the anatomy of a number of the native grass roots. He found these to fall into two types, one thin and fibrous and branched, the other more swollen, with a looser cortex and less branched. The same types of roots have been described by Brenchley and Jackson at Rothamsted and by other workers, but Henrici's observations, in a new area, are very extensive and seem to add some new facts. He points out that the fatter and less sclerenchymatous type of root may turn up upon the same plant that previously formed the fibrous roots and that its formation was associated with the annual rains. He describes the thickening of the cortex by tangential divisions in the layers lying just outside the endodermis, and adds the interesting note that in some roots in successive seasons there may be successive bursts of this growth activity. In the outer cortex, these roots develop large intercellular spaces traversed by radial plates of tissue; Henrici points out that whilst this structure might have value as a type of aerenchyma, under South African conditions such an adaptation often had little significance; on the other hand, he notes that roots of this type of organisation seem to retain water better when, as so frequently happens, the soil is dry over long periods.

Factors Favouring Fruit Production.—Whilst the necessity of intermingling varieties if a good crop is to be obtained in an orchard mainly planted with a self-sterile variety forms the main theme of *Bulletin* 497 (December 1929) of the Cornell University Agricultural Experimental Station, written by L. H. MacDaniels and A. J. Heinicke, the pamphlet is a very interesting example of how scientific and comprehensive the American experiment station worker can venture to make an exposition of a practical problem in horticulture. The main facts as to pollination and fertilisation of flowers are simply explained and then the results are given of various pollination experiments between different varieties of fruit, most of the work being done with apple. These experiments seem to show that under the New York conditions the Delicious apple is one of the best pollinisers, and Baldwin, with pollen of poor germinating quality, one of the least satisfactory. The discussion

of this special problem is then followed by a comparison of fruit-bearing on spurs and upon long shoots, and with an indication of the influence of the water supply at different seasons upon the processes of flower-bud formation and of flower and fruit development. The *Bulletin* is very effectively illustrated and seems a very good example of the way in which an experiment station may make the significance of its labours intelligible to the horticultural public it tries to serve. V. R. Gardner discusses some similar problems in Special *Bulletin* No. 195 (March 1930) of the Agricultural Experiment Station of the Michigan State College upon "maintaining the productivity of cherry trees". This pamphlet will interest some horticulturalists because of its close scrutiny of the value of the practice of pruning, or otherwise treating the trees, so as to obtain most of the fruit upon spurs. Whilst this practice may be justified in Madison because the spur buds are hardier, under Michigan conditions it would seem that it can easily be carried too far and militate against the general growth and total yield of the trees.

Carboniferous Fossils of Tibet.—The late Sir Henry Hayden collected fossils from the west and north-west of Lhasa where no geological observations had previously been made. These have been described by Dr. F. R. C. Reed (*Palæont. Indica*, N.S., **16**, 1930) and comprise Foraminifera, corals, brachiopods, polyzoa, and mollusca. The brachiopods are almost without exception known from the Upper Carboniferous of the Urals or from parts of Asia, and the prevalence of the foraminifer *Schwagerina princeps* suggests that the age is Uralian.

Anatomy of *Mysorella Costigera*.—The example set by the Zoological Survey of India of small monographs on the fresh-water gastropod mollusca of India as a basis for the accurate determination of those species, if any, that act as the intermediate hosts of internal parasites inimical to man, has borne fruit in the production of a paper on the anatomy of *Mysorella costigera* Kuster (*Records Indian Mus.*, vol. 32). The author, R. V. Seshaiya, of the Merchant's High School, Tirupati, gives a very full and careful description of this small hydrobiid mollusc, its habits and anatomy, with abundant illustrations, that cannot fail to be of great use to future workers in the same field, but abstains from drawing any general conclusions to which his researches may have led him.

Superconductivity in Compounds.—The property possessed by some substances of losing all electrical resistance at very low temperature, which, until Prof. W. Meissner discovered it in copper sulphide, was known to occur only with metals, has now been observed by him and H. Franz in some other compounds (*Die Naturwissenschaften*, May 9, p. 418). The new superconductors are titanium nitride, vanadium nitride, the carbides of molybdenum, niobium, and tantalum, and probably also titanium carbide. The nitrides become superconductors at about 1·2° Abs., molybdenum carbide at about 7°, tantalum carbide at 9°, and niobium carbide at 10°. Some oxides were also examined, but none was found to be superconducting. Niobium carbide exhibits the phenomenon at a higher temperature than any other known substance, the nearest to it being Rose's alloy of lead, tin, and bismuth, which was found by Prof. McLennan to have a transition temperature of 8·5° (see NATURE, vol. 125, p. 447; 1930).

Photo-Conductance in Silver Halides.—An attempt to arrive at the mechanism of formation of the latent photographic image is described by F. C. Toy and G. B. Harrison in two papers in the June number of the *Proceedings of the Royal Society*, on photo-conductance phenomena in silver halides. Some silver bromide was set up in an apparatus in which the changes of its electrical conductivity which occur on exposure to light could be studied at short intervals after illumination started. So long as no permanent decomposition was permitted to take place, it was found that the photo-current (an *internal* current through the crystals) started to flow practically at the instant of illumination, and rose to a constant final value, proportional to the intensity of the light, within a few hundredths of a second. This conductivity had the metallic property of increasing with a decrease in temperature below − 150° C., whereas the current flowing in the dark, which is probably due to an electrolytic movement of silver ions, fell off as the temperature was diminished. The photo-current can thus be reasonably ascribed to electrons. The view taken by these investigators is that when silver bromide is exposed to light, some bromine ions are changed to neutral atoms by the photoelectric process, and are then able to react with neighbouring molecules, such as those of gelatin, leaving the silver atoms with which they were originally paired effectively free.

Electrical Transmission of Pictures.—There are many honoured customs in Japan the origins of which are lost in the mists of antiquity. None is considered of greater importance by the people than the series of impressive ceremonies marking the accession to the throne of a new Emperor. In a paper read to the World Engineering Congress at Tokyo on Oct. 31, 1929, and published in *Electrical Communication* for April last, Y. Niwa describes a new system for the electrical transmission of pictures. This system was used to inform the Japanese of the progress of the Coronation ceremonies in November 1928. During the twenty-two days which elapsed between the Emperor's departure for Kyoto and his return to Tokyo, the number of pictures transmitted by the Niwa system between Tokyo and Osaka, a distance of 236 miles, amounted to two hundred and fifty three. The bulk of these pictures were reproduced in the newspapers. As an example of the rapidity of the transmission the following example is given. As the imperial procession and the imperial carriage were moving across the Double Bridge at Tokyo at 7.10 A.M., they were photographed. At 8 o'clock, less than an hour later, the pictures were received in Osaka. At 9.30 A.M. they were published in a four-page supplement of the *Osaka Daily News* (*Mainichi Shimbun*). As in most of the other picture transmission systems at present in use, the picture to be transmitted and the receiving film are wrapped respectively around drums which are made to rotate synchronously and at the same time are pushed forward in an axial direction. At the transmitting end a toothed rotating disc is used to interrupt the light emanating from a source. The pulsating light produced is projected on the picture and reflected to a photo-electric cell, and the electric currents are conveyed by overhead lines and telephone cables to the receiving end. The signals can also be transmitted by radio.

Solubility of Gold in Mercury.—Accounts in the literature on the solubility of gold in mercury are misleading, and it has even been stated that "gold is miscible with mercury in all proportions". In a paper in the May number of the *Journal of the American Chemical Society*, Sunier and White show that the solubility is quite small, about 0·1306 atomic per cent at 20°, or 100 lb. of mercury dissolve about 2 ounces of gold. The amalgamation process for the extraction of gold really depends on surface adhesion.

Agricultural Meteorology.*

THE meeting of the Commission of Agricultural Meteorology of the International Meteorological Organisation at Copenhagen immediately after the Agricultural Section of the Conference of Empire Meteorologists in London testifies to the interest now being taken in that subject.

The problems of agricultural meteorology would seem capable of division into two broad classes, macrocosmic and microcosmic. In the first, we study the influence of weather on crop yields on a large scale, seeking to fill in the general lines of a broad picture by studying recorded crop and weather data over as many years as possible and using statistical methods to determine their interrelations. In the second, the physiological reactions of the plant to the principal weather factors in plant growth—light, heat, and moisture—are considered in detail by a careful study of particular phenomena in plant growth under the completely controlled conditions of the laboratory or in a small-scale field experiment where as many conditions are controlled as possible.

The macrocosmic problem is the especial province of the statistician, and since the pioneer work of Hooker many studies have been published all over the world on the correlation of weather and crops. One might instance the work of Moore, Bradford Smith, and Kincer in America, the very fine work of Wallén, the president of the Copenhagen Conference in Sweden, and Fisher's work in Great Britain, which has effected a very great improvement in the statistical technique employed, by enabling us to relate crop yields to a continuous sequence of weather instead of merely to weather at isolated periods. The importance of this in crop-forecasting is very great.

Important as the distinction is between the two methods of approach, however, they must not be regarded as being entirely unrelated. Valuable as it is to know the degree to which crop yields depend on particular meteorological variates such as rainfall or sunshine, we cannot use our knowledge to the greatest advantage without knowing the reasons for these relations, and these can only be discovered by the microcosmic method.

The position is being rapidly reached to-day in which the statistician who has discovered the existence of interrelations by the large-scale method is also consulted on the planning of detailed experiments by which the reason for these relations may be discovered. For example, under the "Agricultural Meteorological Scheme" of the Ministry of Agriculture, "Precision Record" experiments on wheat are being conducted at several centres on two varieties of wheat. Great care has been taken to use the modern principles of randomisation and replication to ensure valid results, and each time a set of observations is taken, 256 randomly chosen ¼ metre lengths, 128 of each variety, are examined, and measurements of shoot height and counts of leaf number, shoot number, and number of emerged ears are made. In a word, accurate measurements of growth are being obtained, and it is hoped that when the data have been continued over a sufficient number of years, some of the known relations between wheat yields and weather may become explicable in terms of the previous growth of the plant. It is to be hoped that these methods will be greatly extended in the future.

While meteorological data have usually been considered accurate enough for the large-scale correlation of weather and crops, there is an influential body of opinion which considers that the meteorological data at present collected are inadequate for the intensive and detailed study of weather effects on growth phenomena. Thus at the London Conference we find one delegate (Lawrence Balls) saying, "The meteorology recorded in the field crop, that which the plants themselves are experiencing, is not that recorded in the screen. In Egypt at night you can get as much as 5° C. lower temperature, lasting for perhaps only a few minutes, among the plants, than in the neighbouring screen. Then again the question of soil temperature is important. The temperature of the soil in fallow land is very considerably higher than the temperature of soil under the crop." Another delegate (Walter) said: "In the case of wind the effect on plant growth is evidently a function, not only of the age of the plant, but of the duration of high velocities and the change of direction during the period of specified wind velocities. None of these factors is made available for the research worker in the records of the various observatories as usually published."

Again, at Copenhagen we find Angström saying, "Measurements of temperature in the lowest layers of the air, in conjunction with the meteorologico-agricultural problems, ought, it would seem, to be primarily directed towards making clear the connexion between the nature and the quality of the vegetation on the one hand, and the distribution of the temperature in the lower layers of the air on the other". M. Angstrom then goes on to outline the instrumental technique necessary for this purpose. Much the same view is expressed by M. W. Schmidt: "Although plant growth depends so much on weather, there nevertheless exists to-day a huge hiatus between what the agriculturist needs and what the meteorology and climatology provide. . . . Special methods are necessary for this purpose, which relate to the whole life-environment of the plant, that is, the lowest layers of the air and the uppermost layers of the ground—fine measurements which demand a special apparatus." We find other delegates at Copenhagen expressing the same opinion.

Another point of great interest which was discussed both in London and at Copenhagen was Sir Napier Shaw's proposal that the week should be used as a time unit in meteorology. This resulted in a resolution at the London Conference that "In the opinion of the Conference the month is too long a period for the purpose of summarising, for publication, statistics of agricultural meteorology, and the Conference recommends that the week be adopted for the purpose". The Copenhagen Conference was a little more noncommittal: "La Commission attire l'attention des météorologistes sur la proposition de Sir Napier Shaw et recommande d'éprouver dans certaines recherches, la valeur d'emploi de la semaine comme unité climatologique, de manière à reconnaître par l'expérience si l'emploi généralisé de cette unité est convenable".

It is probably true that while the week is a great improvement on the month, there will always be purposes for which individual research workers will require the original observations taken at daily or, it may be, more frequent intervals.

It is not possible in a short article to deal exhaustively with the whole proceedings of the Copenhagen Conference, but one should not conclude without mentioning Holdefleiss's résumé of the work done in Germany on the correlation of crop yields and weather, which seems to follow on the same lines as similar work already done in England and America, and Åkerman's account of what appears to be the very fine work at Svalöf on the study of the relative resistance to frost of different varieties of wheat, a combination of field experiments and of laboratory work in which plants are subjected to cold artificially produced.

J. O. IRWIN.

* Commission de Météorologie Agricole. Procès-Verbaux de la 3ème Réunion, Copenhagen, 1929.

Mutations Induced by X-Rays.

THE effects of X-rays and radium in producing mutations in various economic plants are being studied at the University of Missouri by Dr. L. J. Stadler and others. A general account of this work appears in the *Journal of Heredity* for January last. Dormant and germinating seeds of barley were treated in this way, and the self-fertilised progeny grown separately from the seeds of each head or tiller of a treated plant. Usually only a single culm from each plant has been affected in the primordial stage. Its seeds produce progeny which segregate, thus revealing the recessive character produced by the mutation resulting from X-ray bombardment.

Among 2800 progenies from treated plants, 53 mutations were found, 48 of which were recognisable as seedlings, while 1500 controls produced no mutations. Later, among 20,000 head progenies of treated barley, some 250 mutations were found. These were mainly chlorophyll abnormalities. About 60 per cent of the latter were white, 5 per cent virescent white, and 15 per cent yellow of various shades. They are mostly lethal, and probably represent mutations at many different *loci* in the chromosomes. A few other mutations, such as pale green, non-glaucous or winter barley habit, were found in progenies grown to maturity.

In all these cases, the mutation apparently consists in a change of a dominant (normal) gene to a recessive one in a somatic cell of the embryo or young seedling. In contrast to the frequency of induced mutation in barley, which is diploid ($2n$ 14), they were rare in similar experiments with wheat and oats. This is probably because the latter are hexaploid and the mutations would therefore probably be masked by the normal genes contained in the duplicate pairs of similar chromosomes.

The same method applied to maize produced similar results. Since a single cell of the embryo mutates, a mutation affecting either the tassel or the ear results in the production of heterozygous plants in the second generation, and segregation only in the third. When young growing embryos which are heterozygous are irradiated, the resulting plant may be a chimæra. A plant heterozygous for purple plant colour may have a sector of green tissue. Treatment applied even on the sixth day after pollination may produce chimæras, but from treatment on the first or second day there result plants entirely recessive for a character heterozygous in the seed.

It was found that dormant seeds would withstand a dose fifteen to twenty times heavier than germinating seeds, and that the resulting mutation rate was roughly proportional to the strength of dosage. Storing irradiated seeds for two weeks before planting did not affect the percentage of mutations. Germinating seeds irradiated at temperatures of 10°, 20°, 30°, 40°, and 50° C. also showed no significant difference in mutation rate.

In maize, endosperm chimæras or mosaics were produced, which Emerson has shown are due to chromosome disturbance, that is, to the loss of a chromosome or a portion of one. These losses can be detected when the dominant gene is derived from the male nucleus, for its loss will reveal in the cell the presence of the recessive gene represented in both female nuclei of the triple fusion from which the endosperm is formed.

Maize has ten pairs of chromosomes, and the loss of seven of them can be identified in endosperm mosaics by the genes which they carry. Certain chromosomes or genes appear to be lost much more readily than others. When maize seeds are treated on the day after fertilisation, numerous small mosaic spots appear showing the recessive characters. If the treatment is applied on the fifth day, the spots are so small that the seeds appear stippled and their nature can only be examined with a magnifier. Such treatment also produces chromosome irregularities in the young embryo. The resulting plants may (1) be defective, (2) have 50 per cent defective pollen, (3) show recessive characters for which the treated seeds were heterozygous.

The method is also being applied to the production of bud mutations in the apple. As apple trees are highly heterozygous hybrids in which breeding results are very slow, it appears probable that the application of the method to fruit trees may be of more economic importance than it is in the case of cereals, where natural mutation has already produced great numbers of types for selection and crossing.

R. RUGGLES GATES.

University and Educational Intelligence.

CAMBRIDGE.—Frank Smart prizes have been awarded to E. W. Jones, Jesus College, in botany, and to W. J. Hensman, Trinity Hall, in zoology.

In connexion with the International Botanical Congress, which is to be held in Cambridge in August next, it has been decided to confer honorary degrees on the following: John-Isaac Briquet, director of the Conservatory and Botanic Garden, Geneva; Pierre Augustin Clément Dangeard, professor of botany at the Sorbonne; Friedrich Ludwig Emil Diels, professor at the University of Berlin and director-general of the Botanic Garden and Museum at Berlin-Dahlem; Thore Gustaf Halle, professor and keeper of the Palæo-botanical Department of the Swedish State Museum of Natural History, Stockholm; Lewis Ralph Jones, professor of plant pathology at the University of Wisconsin; Carl Joseph Schroter, emeritus professor of botany at the Technical University of Zurich; Friedrich August Ferdinand Christian Went, professor of botany and director of the Botanic Garden and Laboratory of the University of Utrecht.

EDINBURGH.—The University Court has approved of the institution of a post-graduate diploma in German. It has also agreed to institute a diploma in tropical veterinary medicine. The course for this diploma, which will be held partly at the University and partly at the Royal (Dick) Veterinary College, will occupy six months (October to March) and will commence this year. The curriculum will include classes in parasitology and entomology, bacteriology, meat and milk production, feeding of animals, breeding of animals, epizootology, and a number of special lectures and demonstrations in subjects of special interest to tropical veterinary surgeons.

LONDON.—Dr. J. Scott Lidgett has been elected vice-chancellor for the year 1930-31 in succession to Sir Gregory Foster, Bart., whose term of office expires on Aug. 31. Mr. J. L. S. Hatton, principal of the East London College, has been appointed deputy vice-chancellor for the same period in succession to Dr. Scott Lidgett.

New professors have been appointed to University chairs as follows: *Bacteriology* (University College Hospital Medical School), Mr. C. Cyril Okell; *Chemistry* (University College), Prof. C. K. Ingold, now Professor of organic chemistry in the University of Leeds: *Geography* (Birkbeck College), Miss E. G. R. Taylor: *Physics* (Imperial College—Royal College of Science), Prof. G. P. Thomson, now professor of natural philosophy in the University of Aberdeen.

Mr. H. R. Hamley has been appointed to the University readership in education tenable at the London Day Training College.

OXFORD.—At the Encænia held on June 25 in the Sheldonian Theatre, the honorary degree of D.C.L. was conferred on Sir Hugh Bell, Bart., and that of D.Sc. on Sir Arthur Keith. In presenting Sir Hugh Bell, the Public Orator, Dr. A. B. Poynton, alluded to his eminence in the coal and iron industries, to the widespread influence exercised by his speeches and letters to the Press, to his unceasing advocacy of the principle of free trade, and to the eminent services rendered to the State by the eloquence, insight, and wisdom of his public utterances. Introducing Sir Arthur Keith, the Orator enlarged upon his skill as a great anatomist in disentangling the relationships of the various species and races of primitive man as disclosed by their osseous relics. The fineness of the transition between different races was illustrated by an apt quotation from the "Metamorphoses" of Ovid. His investigation of origins, said Dr. Poynton, had led Sir Arthur Keith to go further, and to speculate on the destiny and goal of all created things. Would that, casting his gaze both forward and backward, he might announce the speedy return of the Saturnian age.

It had been hoped that another distinguished representative of science, namely, Prof. Einstein, would have been present to receive the Doctor's degree; but much to the regret of the University he was prevented by illness from attending.

In the Creweian Oration which followed the bestowal of the honorary degrees, Dr. Poynton alluded to the gift of the Radcliffe Observatory site by Sir William Morris, and pictured Dr. Radcliffe approving of the supersession of his telescope by the stethoscope, and of the charts of the heavens by the temperature charts of the Infirmary.

WALES.—The Council of the University College of North Wales, Bangor, has appointed Dr. J. L. Simonsen (lately professor of organic chemistry at the Indian Institute of Science, Bangalore) to the chair of chemistry, and Dr. F. W. R. Brambell, lecturer in zoology, King's College, London, to the Lloyd Roberts chair of zoology.

APPLICATIONS are invited by the University of Wales for the following scholarships: The Cecil Prosser Research Scholarship of the value of £250 for research in the Department of Tuberculosis; the Mrs. John Nixon Scholarship of the value of £150 for research in the Department of Medicine and Medical Pathology; the Lord Merthyr Research Scholarship of the value of £200 for research in the Department of Surgery; and the Ewen Maclean Research Scholarship of the value of £150 for research in the Department of Obstetrics and Gynaecology. Particulars of the award of the scholarships and forms of application may be obtained from the Registrar, University Registry, Cathays Park, Cardiff.

Historic Natural Events.

July 6, 1928. Hailstorm at Potter, Nebraska.—A remarkable hailstorm occurred during which hailstones "as large as grapefruit" fell, one of which measured 17 inches in circumference and weighed $1\frac{1}{2}$ pounds. This appears to be the largest single hailstone of which there is authentic record. The stones could be heard hissing through the air, and when they fell on ploughed or soft ground they completely buried themselves. Very little damage was done by these stones beyond the unroofing of a few houses, as they fell 10-15 feet apart.

July 7, 1558. Hailstorm near Nottingham.—It is recorded that during a "marvellous tempest of thunder" near Nottingham, hailstones fifteen inches in circumference fell.

July 8, 1707. Great Heat.—This day, called for some time after "Hot Tuesday", was so excessively hot and suffocating in England, because of the absence of wind, that several persons died, or were in great danger of death, at their harvest-work. A former servant of the Rev. W. Derham, F.R.S., a healthy, lusty young man, was killed by the heat, and several horses on the road dropped down and died the same day.

July 8, 1893. Thunder and Hail.—During the afternoon very heavy thunderstorms and tremendous hailstorms, accompanied in some cases by whirlwinds, took place in the north of England. The hailstones which fell at Richmond, Yorks, were up to two inches in diameter. Photographs of two groups of these hailstones, some being split to show the characteristic structure, have been reproduced in many text-books of meteorology.

July 8, 1923. Carrbridge Flood.—After a violent storm, nearly 600 yards of permanent way on high embankments were washed away by a flood at Carrbridge, and a stretch of two miles, between Aviemore and Inverness, was so damaged that traffic could not be resumed for a month.

July 11, 1863. Tornado in Russia.—After very hot and gloomy weather, a whirlwind 700 feet wide levelled houses and trees to the ground, and raised the dust in dense conical columns of black smoke. A post, 31 feet high, 9 feet in the ground, 11 inches in diameter at the base, was lifted whole out of the ground, two large stones were carried up from a ravine on to level ground, children were carried through the air, and iron sheets were carried 24 miles. Hailstones four inches in diameter fell.

July 11-12, 1892. Glacier Flood.—The front of the small glacier of Tête Rousse, south-west of Mont Blanc, gave way, releasing a mass of imprisoned water and ice estimated at 200,000 cubic metres. This flood rushed down the steep valley in a great wave, destroying two hamlets and several houses and causing 200 deaths.

July 12, 1900. Ilkley Flood.—Great damage was done by a sudden flood at Ilkley, Yorkshire, between 2 and 3 P.M. Ilkley is built on the slope of Rombald's Moor, which rises steeply to the southward to a height of 1323 feet, and it seems probable that there was a very heavy downpour on the moor immediately above the town, the water running off the entire breadth of the land as off a roof. A workman said that "the clouds seemed to come down until touching the lamp-posts and then poured out solid water". Every road was turned into a watercourse, and torrents swept through the steep streets of the town for several hours, excavating trenches many feet deep. The lower rooms of houses were filled nearly to the ceilings, the furniture being washed into the streets, lamp-posts were snapped across, and several houses collapsed under the weight of water, with loss of life. After the storm had subsided the kitchens were filled with mud, which was banked high outside the vacant squares where the windows had been. From one house thirty tons of boulders and rubbish were removed, and the débris swept by the flood into the River Wharfe formed a great sand-bank. In one part of Ilkley the rainfall was 5·40 in., the greater part of which fell in a single hour.

Societies and Academies.

EDINBURGH.

Royal Society, June 2.—**O. F. T. Roberts**: On radiative diffusion in the atmosphere: The processes of long-wave low-temperature radiation in the atmosphere have been studied with the view of investigating the extent to which they may be regarded as diffusion-like; the decrease of water-vapour with height is taken to be exponential, that of temperature to be constant up to the tropopause, and then to be zero. Full allowance is made for the radiation being diffuse. The expression for the upward flow of radiation is obtained in the form of a power series in the temperature gradient in the troposphere; the coefficient of the first power of the temperature gradient is defined as the "coefficient of radiative diffusion". There is a certain amount of ambiguity about the coefficient so defined.—**D. Jack**: A simple spectrum comparator. The instrument, which is inexpensive and easily constructed, consists of a microscope with two objectives giving images of two spectrum photographs or other objects in a single eyepiece. The use of a prism silvered for external reflection allows of the photographs being placed side by side on the microscope stage. By this arrangement the length of the objects which the instrument can accommodate is not restricted by the size of the instrument.—**W. O. Kermack, R. H. Slater**, and **W. T. Spragg**: Certain quinoline and benzacridine derivatives yielding coloured adsorption compounds with iodine. In the case of the active aminoquinoline compounds the colour is usually developed in presence of solutions containing iodine at a concentration of the order of $N/10,000$, whilst in the case of the benzacridine compounds the colour is still apparent at concentrations of $N/100,000$ or even less. The effect of variation of concentration of compound iodine and hydrogen ions and other circumstance has been investigated. The chromogenic property appears to depend not on the nitrogen atom in these compounds but on the molecule as a whole. The compounds investigated differ from most of those previously known to give colours with iodine in that they are basic and form colloidal solutions in which the particles are positively charged.—**S. G. Jones**: A study of apothecial development in the leaf-spot disease of red clover. The disease is caused by the fungus *Pseudopeziza Trifolii*. The apothecial fructifications occur singly, but far more frequently in small clusters on both sides of the leaf and at the same spot. Their development is initiated by a small group of vegetative cells accompanied by an "ascogonial coil" and invariably situated within sub-stomatal cavities of the leaf. The ascogonial coil is capable of branching and extending itself into neighbouring stomatal cavities, there to initiate fresh apothecia. The ascogonial coil and its branches, however, prove to be abortive structures, but their proximity to certain cells of the vegetative mycelium is believed to exercise a stimulus, possibly nutritive, causing these cells to become multinucleate. The development of apothecia proceeds in an apogamous manner from these multinucleate cells, termed "primordial cells". They give rise to the ascogenous hyphæ. The terminal cell of a primordial group invariably passes out to the exterior of the leaf at a stomatal pore, pointing to a respiratory function.—**E. L. Ince**: Tables of the elliptic cylinder functions.

CAPE TOWN.

Royal Society of South Africa, Mar. 19.—**A. Pijper**: The blood-groups of the Bantu.—**F. G. Cawston**: Some observations on the embryonic radula of Limnæidæ. In the embryonic stage it is possible to recognise the marginal teeth with their denticles, the tricuspid laterals and the narrower central tooth of each row. Radulæ are best mounted in glycerine jelly. The number of teeth increases rapidly after the egg hatches, until the mature individual mollusc possesses several thousand teeth.—**R. H. Compton**: The flora of the Whitehall district.—**V. H. Brink**: A comparative study of the sacrum of the Griqua.—**C. Gordon** and **L. Hogben**: The separate identity of the pressor and pigmentary effector activity of pituitary extracts. When exposed to the action of cold normal sodium hydroxide for two hours, the pressor activity was found to be reduced more than 90 per cent. The pigmentary effector activity increased. The increase was doubtless due to the lack of interference from concomitant vaso-motor phenomena.—**D. Slome** and **L. Hogben**: Further observations on the relation of the pituitary gland to the chromatic function of *Xenopus Lævis*. The comparison of reactions of totally hypophysectomised and normal toads (*a*) to photic stimuli and (*b*) to the injection of posterior lobe extracts yield data which reinforce the conclusion that the *W*-mechanism of a previous communication can be identified with the anterior lobe of the pituitary gland.—**Enid Hogben**: Some metabolic changes associated with pigmentary effector activity in *Xenopus Lævis*. Eyeless animals have a significantly higher respiratory rate than eyed animals. The effect of removing one or both lobes of the pituitary gland lowers the dermal respiratory rate by about 24 per cent, and the calcium and magnesium content of the serum by about 30 per cent. Significant differences occur between males and females in all cases; males had a higher respiratory rate than females, and the calcium and magnesium content of the serum was lower in males than in females.—**L. Hogben**: Some remarks on the relation of the pituitary gland to ovulation and skin secretion in *Xenopus Lævis*. Autopsy of large females kept for two years after total operative removal of the pituitary revealed the fact that the ovary had undergone almost complete involution in all cases. Implantation of glands from other individuals or injection of anterior lobe extracts induced ovulation.—After removal of the whole pituitary gland or the anterior lobe alone, the copious secretion of slime so characteristic a response of *Xenopus Lævis* ceases entirely. Injections of anterior lobe extract produce within a few hours complete shedding of the skin. The autacoid is heat stable and ether soluble.—**A. Zoond**: (1) The localisation of respiratory exchange in the scorpion. Occlusion of the book lungs of *Opisthophthalmus capensis* with a thin film of rubber solution. Determinations of oxygen caused total inhibition of respiration. (2) The localisation of respiratory exchange in the polychæte *Bispira Voluticornis*. Cutaneous respiration is 32 per cent of the total, and the branchial filaments are the principal region of respiratory exchange.—**L. P. Bosman** and **H. Zwarenstein**: The blood-sugar in normal and eyeless *Xenopus Lævis*. Higher in eyeless animals than in normal specimens.—**Sir Thomas Muir**: (1) Note on sums of N-line minors pertaining to an N-by-$N+2$ array. (2) Note on the derivatives of the eliminant of two binary cubics.

ROME.

Royal National Academy of the Lincei, Mar. 2.—**A. Angeli**: Pyrrole blacks.—**L. Cambi** and **T. Ricci**: Arylnitrosoferropentacyanides: formation from arylhydroxylamines and nitroprusside. In aqueous alcoholic solution, the reaction between sodium nitroprusside and phenylhydroxylamine yields first the hyponitrosoferrocyanic complex, $[(CN)_5\ FeNO]^{''''}$,

which then passes into the aquoferrocyanide $[(CN)_5FeH_2O]^{III}$, which then passes into the aquoferrocyanide $[(CN)_5FeH_2O]^{III}$, and this, under the action of the nitrosobenzene formed in the first phase, is converted into the arylnitrosoferropentacyanide complex $[(CN)_5Fe(NO)C_6H_5]^{III}$.—**B. Segre**: Construction of bisextuples of straight lines.—**Maria d'Ascia**: Test of the method of least squares for the numerical integration of linear differential equations.—**M. Brelot**: Point sources of heat in a radiating plane in thermal equilibrium.—**A. Wintner**: The anharmonic analysis of secular inequalities furnished by Lagrange's approximation.—**A. Belluigi**: The tectonics of certain deep structures discovered gravimetrically in the Paduan plane.—**Stefano Lodovico Straneo**: Moll's vibration galvanometer. Various points connected with the action of the Moll galvanometer are discussed. **B. Rossi**: A method for the study of the magnetic deviation of penetrating rays. **E. Bossa**: The Hall effect for the metals, nickel, iron, and copper, in weak magnetic fields. For nickel and iron, the course of the Hall coefficient in weak magnetic fields is substantially different from that in strong fields, the gradual increase observed on diminution of the field becoming rapid at about 30 gauss for nickel and at about 6·2 gauss for iron; this rapid increase is maintained at least so far as 2 gauss and 0·2 gauss for nickel and iron respectively. With both metals, dissymmetry of the galvanometer deviations is noted on inversion of the magnetic field. With copper, on the other hand, no trace of such dissymmetry exists, and the Hall coefficient exhibits only a slight increase as the strength of the magnetic field is lowered to about 1 gauss. **G. Bargellini** and **A. Grippa**: 2:5-Dibromophenetidine. Bromination of phenacetin with a quantity of bromine corresponding with four atoms per molecule results in the formation of 2:5-dibromophenacetin, which may readily be hydrolysed to 2:5-dibromophenetidine The results obtained confirm the conclusion previously drawn, that the first halogen atom introduced into the phenacetin molecule enters in the ortho-position to the ethoxy group and the second in the ortho-position to the acetylamino group. **P. Principi**: Observations on the age of the travertines of Ellera in the neighbourhood of Perugia. **G. Brunelli**: Eutrophy from stagnation in artificial lakes. **P. S. Israel**: Investigations on chronaxia. (3) Action of lithium on the chronaxia of the neuromuscular preparation of the frog. Lithium chloride has a distinctly unfavourable action on this phenomenon and cannot replace sodium chloride, this action being exerted particularly on the nerve and to a less extent on the muscle. **B. Monterosso**: Cirrepedological studies (6). Behaviour of *Chthamalus stellatus* in different experimental conditions. **M. Curzi**: First observations on the mutation of a hyphomycetes.—**G. Cannicci**: Contribution to the study of glutathione in Teleostei. Observations on the method of determination (1). Of the two methods which have been suggested for the determination of glutathione, the nitroprusside method, especially as modified by Randoin and Fabre, although not absolutely accurate, gives results sufficiently exact for physiological experiments.—**U. Cassinis** and **L. Bracaloni**: Hydremic curves caused by rest and by physical exercise (2). **S. Visco**: Protein ration and energy ration. When given a diet deficient in protein, rat slowly lose in weight and ultimately die, no matter what the quantity of energy ration consumed. Thus, physiological and economic utilisation of the ternary substances absorbed is possible only to organisms satisfied as regards their protein requirements.—**V. Rivera**: Cosmic waves and cellular multiplication (germinating seeds) (1).

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, Vol. 16, No. 3, Feb. 15).—**Francis Bitter**: On the diamagnetism of electrons in metals. A formula for diamagnetic susceptibility of free electrons is calculated, taking into account the wave structure of the electron: it has the same form as the classical formula but the mean free path is replaced by $a/4$ where a is the grating constant of the cubic lattice considered.—**Alexander Goetz**: On the experimental evidence of the mosaic structure of Bi single-crystals. Bismuth single crystals of a definite orientation were grown by a special method and examined microscopically with and without etching. Evidence is obtained that the single crystal contains 'blocks' of a definite size independent of the perfection of the crystal provided the crystal is not plastically deformed. Illustrations of the structure observed are given. **George H. Shull**: The first two cases of crossing-over between old-gold and bullata factors in the third linkage group of *Œnothera*. **J. T. Patterson**: Somatic segregation produced by X-rays in *Drosophila melanogaster*. Cultures of eggs and young larvæ of a cross between yellow-white females and eosin-singed males were treated with X-rays and the F_1 females examined. The criterion for somatic segregation was the occurrence of a gray-singed area adjacent to a yellow non-singed area, and this was found in a few cases. **P. ten Bruggencate**: The radial velocities of globular clusters. There is a linear correlation between the displacements of spectral lines for globular clusters, corrected for solar motion, and galactic latitude, similar to that between line displacement and distance of the spirals. **Wilder D. Bancroft** and **C. E. Barnett**: (1) Solid protein hydrochlorides. The pressure-concentration isotherm for hydrogen chloride gas and charcoal is a smooth curve typical of adsorption; zein gives a similar curve. Hexamethylene tetramine gives a curve with four 'flats'; arachin, casein, edestin, fibrin, and gliadin each gives one or more 'flats'. A 'flat' indicates formation of a compound.—(2) Adsorption of ammonia by proteins. Using the method indicated above, it is shown that ammonia gas combines with tartaric acid (as already known) and with p-aminobenzoic acid, but not with aminoacetic acid or the proteins used above.—**Linus Pauling**: The structure of the micas and related minerals. The general formula given for the micas is $KX_nY_4O_{10}(OH, F)_2$, with $2 \leq n \leq 3$, where X and Y are cations of co-ordination number 6 and 4 respectively. The brittle micas have a similar formula in which calcium replaces potassium. **Hans-Joachim Schumacher** and **Gerhard Sprenger**: The decomposition of nitrogen pentoxide at low pressures. Pressures of 0·2–0·004 mm. mercury were used. There is no marked falling off of the unimolecular constant down to about 0·06 mm. pressure but a decrease below this. Experimental procedure is fully described. **Elizabeth T. Stafford** and **H. S. Vandiver**: Determination of some properly irregular cyclotomic fields.—**Ernest W. Brown**: On an extension of the Fourier theorem giving rapid methods for calculating the constant part and the coefficient of any periodic term in the disturbing function.—**M. S. Knebelman**: Content-preserving transformations.—**E. T. Bell**: Simplicity with respect to certain quadratic forms.—**Aristotle D. Michal**: (1) The differential geometry of a continuous infinitude of contravariant functional vectors.—(2) Projective functional tensors and other allied functionals.—**G. A. Miller**: Non-Abelian groups admitting more than half inverse correspondencies.—**M. H. Stone**: Linear transformations in Hilbert space. (3) Operational methods and group theory.

Diary of Societies.

FRIDAY, JULY 4.

GEOLOGISTS' ASSOCIATION (at University College), at 7.30.—Dr. C. T. Trechmann: The Relation of the Permian and Trias in North-East England.—J. J. Hartley: The Volcanic and other Igneous Rocks of Great and Little Langdale, Westmorland.—*Paper to be taken as read*:—F. Jessop: The Agates and Cherts of Derbyshire with a Brief Account of the History of the Lower Carboniferous Limestone of the Peak District.

ASSOCIATION OF ECONOMIC BIOLOGISTS (at National Institute for Research in Dairying, Shinfield, near Reading).

MONDAY, JULY 7.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

TUESDAY, JULY 8.

INSTITUTE OF TRANSPORT (at Glasgow).—E. J. H. Lemon: Railway Amalgamation and its Effect on the Workshops.—Sir G. C. Buchanan: The Economics of Port Development and Administration.—W. J. Thomson: Long-Distance Omnibus Services—their Place in the National Scheme of Transport. (Continued on July 9 to 12.)

WEDNESDAY, JULY 9.

INSTITUTION OF MINING ENGINEERS (at Birmingham). (Continued on July 10 and 11.)

CONFERENCE.

JULY 8 AND 9.

SOCIETY FOR EXPERIMENTAL BIOLOGY (in Department of Zoology Birmingham University).

Tuesday, July 8, 2.15 to 3.45.—V. B. Wigglesworth and E. K. Sikes: The Hatching of Insects and the Appearance of Air in the Tracheal System.

Prof. H. Munro Fox: Spectroscopic Analyses of Tissues.

P. D. F. Murray: The Differentiation of the Somites and Limb-Buds of the Chick.

5 to 6.—D. L. Gunn: Water Metabolism of the Cockroach.

R. Snow: Some New Aspects of Correlative Inhibition.

Wednesday, July 9, 10 A.M. to 1. Prof. W. Stiles: The Toxic Action of Alcohols and other Substances on Plant Tissues.

W. N. Howarth: Polymeric Forms among Carbohydrates.

E. L. Hirst: High Polymerides in the Carbohydrate Group.

Prof. J. H. Priestley: The Plant Cell Wall.

W. T. Astbury: The Structure of Wool-fibres by X-ray Analysis.

2.15 to 3.45.—L. C. Beadle: Effects of Low Salinities on Water Content and Respiration of Marine Animals.

C. F. A. Pantin: Adaptation of *Gunda ulvae* to Changes in Salinity.

F. T. K. Pentelow: The Fauna of the River Lark.

4.30 to 5.30.—J. Gray and S. B. Setna: The Growth of Fish Scales.

M. A. Tazelaar: Further Work on the Effects of a Temperature Gradient on the Early Development of the Frog.

CONGRESS.

JULY 10 TO 12.

OXFORD OPHTHALMOLOGICAL CONGRESS (at Oxford).

Dr. H. M. Traquair, Sir Farquhar Buzzard, Bart., Prof. J. A. Gunn: Symposium on Toxic Amblyopia.

Sir Oliver Lodge: Modern Theories on the Nature of Light.

Dr. H. Friedenwald: Pathological Changes in the Retinal Blood Vessels and their Significance (Doyne Memorial Lecture).

Prof. A. Schuller: Recent Developments in Radiology Associated with Ophthalmology.

Prof. J. Gonin: Detachment of the Retina and its Treatment.

No. 3167, Vol. 126]

Education, Environment, and the Criminal.

EVERY year a considerable sum of public money is expended on the issue of official publications —blue books, which it is to be feared the general public too rarely reads. Yet this is a pity; for blue books are sometimes entertaining and usually instructive. Elsewhere we give some figures taken from the returns of criminal statistics for England and Wales for the year 1928 issued by the Home Office. From the data there given it will be apparent that this official publication is of interest to a wide audience—wider, indeed, than the specialists in the study of crime and the criminal, or indeed in any one branch of social reform which impinges on the criminal world. For criminal statistics are not merely a gauge of the criminal tendencies of our population, any more than they are solely an index of the efficiency of our police organisation in detecting crime. Infinitely more suggestive to regard them as a tabulation of the less gratifying products of our social system—an indication of some defective bearing in the machinery by which the daily life of the community is regulated and carried on.

In a perfect society there would be no crime—not necessarily as a result of the perfection of the individual, but because of the complete adjustment of that society to the satisfaction of the needs of the individual. The primal nature of man remains unaltered through the ages. It is based upon certain fundamental necessities which are perennial and common to all living things. These are the urge to the preservation of the individual and the urge to the perpetuation of the race. When once this postulate is grasped the whole problem resolves itself into a matter of adaptation.

The attempt to secure the full satisfaction of the needs of the individual by moulding the environment to his requirements is the genesis of culture and of society. It lies at the roof of Utopias framed by philosophers from Plato to H. G. Wells; it is the motive power of social reform and the justification of the world-old urge towards democracy. For, unfortunately, even in the earliest stages of man's history as a social being, the environment was imperfectly adapted to the needs of all individuals. Differences of age, physique, sex, and individual character made for imperfect adjustment. There must always have been an under-dog. Even in the simpler societies, whether patriarchal or matriarchal, the exercise of family control entails a cramping of individuality by regulations which sooner or later are regarded by someone as harsh, uncon-

scionable, or unnecessary. Their transgression inevitably follows and the eyes of authority behold a crime. As society becomes more complex, maladjustments as between individuals and the environment become more numerous and crime increases. For whatever means the individual may adopt to correct that maladjustment, whether it be murder or merely exceeding the speed limit, if it contravene a regulation laid down by the authority of society it constitutes a crime.

Thus 'crime' is purely a relative term and in the history of mankind its connotation has varied with the variations in type and the advance of the social organism.

It must be remembered, however, that to regard society as a means of securing the full satisfaction of individual needs may tell less than half the story. It is obvious that the environment with which a man may find himself at odds is a complex of individuals like unto himself, and in the satisfaction of his own needs he is precluded from impeding the satisfaction of the legitimate needs of others. Just as the patriarch in a primitive community imposes his will upon the members of his group, so in a more highly organised society the will of that society, whether it be embodied in a despot, a constitutional monarch, or in the representative assembly of the people, exercises itself to guard against encroachment by the individual. Hence the paradox that the social organism which was created originally to provide an environment which would admit of the complete self-expression of the individual almost immediately becomes a medium to which he must adapt himself. Self-expression is given a free rein so far, and so far only, as it does not come into conflict with the limitations imposed by society.

It is a matter of importance to stress the fact that crime has no fixed connotation but that it varies at different grades of culture. Even murder, the most serious injury to the person, at certain stages of social development is a private matter for the victim's immediate group and not a concern of the community as a whole. This way of looking at the matter survives even in Europe, where in some of the less advanced communities the family or tribal vendetta survives under a comparatively highly organised system of government. Plural marriage, which is perfectly legitimate in a polygamous society, becomes the crime of bigamy in a society organised on a monogamous basis. Incest, a criminal offence, though only since 1908 in England, has varied in definition in different ages and in different societies according to the forbidden degrees, and a form of union which we would now class as incestuous constituted the primary form of royal marriage in ancient Egypt.

Any contravention of a regulation laid down with communal authority may constitute a crime. In the army a man's 'crime sheet' records behaviour contrary to regulation and may contain no entries in any sense of 'criminal' in common usage. For the purpose of the "Criminal Statistics", crimes in the sense of indictable offences may range from murder and manslaughter to stealing a dog or "inciting an infant to bet". Each year the list of such offences becomes longer. Additions were made to no less than twenty classes of offence by legislation which came into force in England and Wales in 1928. They affected such widely varying matters *inter alia* as fraud, forgery, money-lending, road-transport lighting, and the protection of the lapwing.

Thus legislation, and especially legislation of the grandmotherly or meticulous type, more particularly if it does not have an overwhelming weight of public opinion behind it, leads to an increase of crime. It adds to the number of offences and thereby swells the roll of those who offend. The prohibition laws of America afford a peculiarly instructive example—at least so far as it is possible to judge from the outside. There the union of various interests with ulterior motives—of these perhaps the most potent the desire to eliminate the influence of the saloon-keeper from the sphere of politics—joined with the temperance movement to attain their object through the prohibition laws. These public opinion—the ultimate tribunal—has not merely not been strong enough to enforce, but it would seem as if as a whole it has not even desired to enforce them in their entirety. Hence 'bootlegging' and a whole series of customs offences, with the acts of lawlessness which accompany them, as well as the illicit manufacture and sale of alcohol, now help to swell the list of crimes.

It requires very little consideration of the variety of and variation in criminal statistics to show that those anthropologists who a generation and more ago sought to fix a criminal physical type were attacking a social problem on too narrow a front. In so far as certain stigmata denote physical and mental degeneration they may be taken as indication of potentialities in certain directions, which, given certain conditions, are likely to become actively criminal. The force of heredity is no more negligible in human relations than in animal breeding. But in a modern society the effects of heredity and of environment are almost inextricably interwoven. The study of the evolution of man and his congeners, the great anthropoid apes, points to the

fact that while the latter have survived by an early specialisation adapting them to their environment but limiting their advance, man has survived through an infinite adaptability to varying conditions. Hence it is no longer possible to look upon the criminal, that is, the criminal in the more serious sense of the social outlaw, as a type— a throwback or a survival in any real sense. He is a failure in adaptation. Normally man must be regarded as infinitely educable. The criminal, however, even the criminal of habitual type, is an individual of imperfect inhibition. His conduct may be conformable to an earlier stage of culture: but as things are it is a maladjustment with his social environment. The man who steals to procure food which will save him from starvation takes that which in a more primitive society would be procurable by his own effort or would be given him for the asking. For here the necessities of life are common to the members of the group, or are the product of group activity: but in a society in which his act has come to be looked upon as a crime, he shows that either he has not responded to training or he has been imperfectly educated to survive in the conditions imposed upon him by society.

Criminal statistics, then, serve as an index of the degree to which there is a lack of adjustment as between the individual and the requirements imposed by life in any given community. In the imperfect world in which we live, it cannot be hoped to eliminate crime, but with these data as a starting-point it is possible to probe for the causes which retard progress towards a state of social equilibrium. On one hand, it may be asked whether the incidence of crime is such as to point to an undue proportion in the community of a class congenitally unfitted by physique and mental constitution to acquire a habit of conduct in accordance with the standard of the community— a problem for the expert in the study of delinquents and the eugenist. On the other hand, the number and character of the crimes may suggest an inquiry whether the training by which society seeks to secure that the individual is brought into harmony with, and fitted to survive in his environment is suitable and effective— the province of the educationist. Moreover, it must not be overlooked that the environment itself may be at fault. Social conditions may be such as to render nugatory all efforts towards individual training, or by force of unduly harsh or unnecessary legal and social restrictions make demands which an appreciably significant proportion of members of the community is unable to meet, constituting a call for social or legal reform which should not be ignored.

The Great Chemists.

Das Buch der grossen Chemiker. Herausgegeben von Dr. Günther Bugge. Band 1: *Von Zosimos bis Schönbein.* Pp. xii + 496 + 42 Tafeln. (Berlin: Verlag Chemie G.m.b.H., 1929.) 24 gold marks.

THE appearance of any work on the history of chemistry which is more than a sketch of the subject is so infrequent that a general expression of satisfaction and a recommendation seem inevitable in all cases, and are usually given to the exclusion of any detailed criticism. There are, however, certain general errors which seem fated to recur in all such works, and it may be useful, in addition to the statement that the present work is one which every chemist should add to his library, to notice some of these here.

The present volume is a composite production and suffers inevitably from the faults of such. The treatment is uneven and the value of the contributions varies rather considerably with the authors. The subject matter as a whole is, however, of high standard, and in the cases where the original sources have been used it contains many points of interest and importance. In many cases, however, the sources have clearly been secondary, or even further removed from the originals. Common and well-known errors, therefore, appear again, in many cases with reference to the secondary or tertiary literature from which they have been taken. It is impossible to refer to all such cases, but a few examples will be given. The statements on pp. 369 and 373 that Dalton was indebted to Richter are not in accordance with the facts as set out in the careful examination of the question published by Meldrum many years ago, and that on p. 391 that Mayer took account of Gay-Lussac's experiments on the expansion of gases into a vacuum is given with a reference to a secondary source. If the author had read Gay-Lussac's work and had seen a criticism of this statement published a few years ago, he would scarcely have repeated this old error. The discussion of the early work on hydrofluoric acid follows the usual incorrect course (p. 284): the facts were published by the reviewer some years ago.

Although an American writer is taken to task (p. 224) for giving Geoffroy's name incorrectly, there are numerous examples of the mangling of names in the present volume, particularly those of Englishmen or English places. On the same page as the mis-statement about Mayer and Joule we find "Sir Dugald Clirs"; on p. 45 we find "Sommerset" (and are, incidentally, told that

Bacon studied in the " Hochschule zu Oxford ") ; a little further on (p. 46) we find " Brever " for Brewer and the date of Jebb's edition of the " Opus Majus " is incorrectly given ; " Wresham " appears for Wrexham, and " Clerc Maxwell " does duty for the name of the great physicist. It would be well to publish a list of errata in the forthcoming second volume.

The treatment, on the whole, is moderately international, but the book is clearly intended mainly for German readers, and its reception in other countries must, in consequence, pay the price of this. As an example we may refer to the statement, after being told that Agricola had 'lifted' [abgeschrieben] large portions of Biringuccio's " Pirótechnia " in the composition of his " De Re Metallica ", that, after all, the Italian's name shows that he is of " germanische Abstammung The usual sneer at " die englische Pruderie " occurs (p. 410), in this case, however, in connexion with what appears to be a wholly imaginary example, so that perhaps our love of fair play and regard to veracity have been mistaken for prudery. In very few cases do notable English books appear to be known to the writers, and the literature references are seriously incomplete in this respect. Thus, Darmstaedter, in his article on Agricola, refers only to his own edition of the " De Re Metallica ", without mentioning Hoover's masterly work, and many other examples could be quoted.

As an example of the lack of knowledge of English and American scholarship on the part of many authors, the article on Roger Bacon may be quoted. The relations of Bacon with the Church are in the old-fashioned mid-Victorian Huxley-Spencerian vein, namely, that of an enlightened experimenter struggling with ignorant bigotry. In reality we know that Bacon's " Opus Majus " was not written until after pressing invitations from the Pope, and that Bacon 'got himself into hot water' not by his scientific views but by his wholly unnecessary personal abuse of highly placed members of his order. It is to be feared that the enlightened modern eminent man of science is often quite sensitive even of scientific criticism : what he would do if he were called a blockhead by his inferiors, and had the same freedom of action as Bacon's superiors, we do not wish to contemplate. All recent studies of Bacon's chemical work, such as those of Little, are completely ignored, and the article is very poor.

The treatment of Zosimos follows the usual lines. After the statement that Berthelot and Ruelle's edition is very defective, which seems to be regarded as a pious duty by all recent German authors who compile from it, the so-called 'mystical' element in Alexandrian chemistry is stressed. It should be realised that Alexandrian authors in general introduced some complication into their writings which we avoid, in that they attempted to take account of the existence in Nature of God and of the soul. The treatment of a scientific subject gains in clearness and objectivity by ignoring these, but it may perhaps be suggested that it becomes rather one-sided. As philosophers, the Alexandrians were not satisfied by chemical cookery. The contributions made to *practical* chemistry by the early chemists of Alexandria are not made sufficiently clear. The reviewer will show in another place that the theory of the four primary colours of Demokritos, whose authority is invoked by all the early writers on chemistry, probably influenced the first theories in a way which does not seem to have been fully recognised, and that under its influence the theory and practice of the science descended in a perfectly natural way.

The article on Geber adds rather considerably to the complexity of the subject, although here much recent work is carefully considered. We knew from Berthelot that some of the Arabic works of Jabir were quite different from the " Summa " of Geber, but it is now suggested that these Arabic works are not authentic. It may be noticed in passing that the author of the " Summa " might have been English.

The treatment of the medieval writers is generally very unsatisfactory. Recent scholarship is practically ignored and in several cases the chemical aspects are referred to only in the very briefest way. Instead of an attempt to deal with the undoubted interest which some of the great schoolmen showed in chemistry, with careful references to the original sources, we are given merely a mass of undigested rhetoric from which we strive in vain to extract a few grains of objective truth. The general character of these articles may be judged from the following quotation from the later one on Paracelsus (who is treated highly sympathetically) : " Über allen Dingen zittert der Abglanz eines fernen Glückes. alles Böse ist transparent und macht das Gute sichtbar, wie alles Nein das Ja, wie das Schwartz das Weiss und wie der Teufel Gott ". There is much in this vein.

When the seventeenth century is reached the articles become more interesting and objective and in some cases contain really valuable material. It would perhaps be unfair to select certain article-

as especially good, since so much depends on the particular taste of the reader, but the reviewer found the following of great interest: Glauber, by Walden—an outstandingly good article; Libavius, by Darmstaedter; Klaproth and Mitscherlich, by the editor; Faraday, by Ostwald (apart from the error on p. 424 as to the source of the nomenclature of electrolysis, which is really due to Whewell, and the usual over-emphasis of the opposition of Davy to the laboratory assistant's F.R.S.). Articles which seemed less interesting, and, in some cases, to be more based on secondary sources, were those on Albertus Magnus, Paracelsus, Van Helmont, Lully, Berthollet (scrappy), and on Fourcroy and Vauquelin (merely dull).

The book, which is well printed and reasonably priced, must, like other recent German works on the history of chemistry, be used with caution and in close proximity with the originals. For the general reader who finds no difficulty with the language and is not much concerned with minute accuracy, it will be found very interesting. A second volume, bringing the study down to Emil Fischer, is promised and will be welcomed, but the editor might well impress on his collaborators the necessity of a rather broader outlook, a closer scrutiny of the original sources and less leaning on other historians, and more attention to recent scholarship in other lands than Germany.

J. R. PARTINGTON.

Cocci and Hæmophilic Bacteria.

Medical Research Council. A System of Bacteriology in relation to Medicine. Vol. 2. By C. H. Browning, W. Bulloch, J. H. Dible, A. Fleming, F. Griffith, R. Tanner Hewlett, J. E. McCartney, T. J. Mackie, D. G. S. McLachlan, J. W. McLeod, W. Mair, E. G. D. Murray, G. H. Percival, W. M. Scott, A. L. Taylor, W. J. Tulloch, H. D. Wright. Pp. 420. (London: H.M. Stationery Office, 1929.) 21s. net.

THE volume of the Medical Research Council's "System of Bacteriology" before us deals with "Cocci and Hæmophilic Bacteria". A comparatively brief chapter is devoted to the staphylococci. There is an extremely interesting short note on the history, and Prof. Bulloch has appropriately emphasised the important and really primary work done on these organisms by Ogston in Aberdeen. The whole chapter, though brief, is well written, and gives a sufficiently detailed and accurate account of this group of bacteria.

Chap. ii., on the streptococci, is necessarily a long one, and occupies more than double the space given to any of the other cocci. This indicates the vast amount of work that has been done, and particularly during recent years, on this group of organisms. The list of references in itself indicates the amount of work that would require to be expended even to read superficially all the papers that have been published on this subject, and the chapter shows evidence that the reading by some of the authors has not been very carefully done. We think this chapter has also suffered from the multiplicity of authors. The early parts by McLeod are well done, and this can also be said of the section by Mackie and McLachlan. It may be desirable in a volume which is to be one of reference that an account should be written of results recorded by various authors as to the finding of streptococci in certain conditions of the skin, but we do feel that more judgment might have been used in the selection of published work in which there was, to say the least, evidence of some value brought forward to establish a claim to causal relationship. We do not think that judgment has been shown in the section by Percival.

To write above seborrhœa corporis, that "Although the characteristics of the streptococci isolated from these lesions have not yet been investigated, *it is very probable*, from a comparison with the hæmolytic streptococci isolated from impetigo, that the organisms in question are capable of elaborating a diffusible toxin. *If this is the case* the eczema reaction which is provoked may be due to the direct action of such a toxin . . .," without giving any evidence that the streptococci are not mere saprophytes in this condition, is in our opinion not worthy of being published.

The chapter on mouth streptococci seems to be somewhat confused, and we are at a loss to know whether this section is confined to this group, as the heading and the table of contents would suggest. Does the author maintain that the streptococci of rheumatic fever and of subacute endocarditis dealt with here are all mouth streptococci? There is a great deal of valuable information in this chapter, but it is not well arranged, and it is, in our opinion, too much dominated by the personal views of the author. Thus, in referring to the work of Leschke and Auerbach, who think that the best time to examine the blood is when the temperature is high, we are told that there is no convincing evidence that this is so, and the only fact given in support of this statement is that "the writer's experiments indicate that the number of organisms in the circulating blood do not undergo

 B 1

great or sudden variations". No other evidence is given, and not even a reference to the author's experiments. On the following page, it is stated that "the original infection of the valves must result from an invasion of the blood stream by streptococci", and again, "they enter the blood stream from foci of infection". Surely it is almost certain that this entry and this spread will give rise to temperature, and if blood culture is made at that time the bacteria are more likely to be found than when the organisms have got settled down in the valves.

On rheumatism, in reference to the work of Beattie and Yates, the author states: "If their figures are considered in detail, it will be found that streptococci were isolated from the synovial membranes in 20 per cent of all cases". In answer to this it is stated that the author (1925) has pointed out that "similar organisms can be isolated from the heart blood of a not dissimilar percentage of cases dead from any cause". These statements are no doubt correct, but they are misleading. The author ignores altogether the experimental results obtained with the organisms in the 20 per cent of the cases, the rheumatic history of these cases, and particularly that in double the number of cases done at the same time the synovial membranes contained no streptococci, and that therefore general blood infection was excluded. The remaining parts of this section, on the enterococcus (though we disagree with the differentiation between this and *S. faecalis*), the parts on the anaerobic streptococci and on chemotherapy, are all important contributions which add considerable value to this whole chapter.

The chapter on pneumococcus is a very exhaustive study of this organism, and the authors have given very careful attention to detail. The views of various authors are given with extreme fairness and with excellent critical judgment. On the gonococcus, Tulloch writes with the authority of one who has himself done a considerable amount of work on the subject, and in consequence is quite familiar with the work of others. Nothing but praise can be given to this section, and we would specially emphasise the valuable part on practical diagnosis. The section on meningococcus (and, by the way, we are glad to see the protest against the American name, *Neisseria intracellaris*) is again evidently the work of an expert on the subject. We do not agree with all Dr. Murray has written—and particularly with the emphasis laid on identification by cultural characteristics—but it is a well-written article and gives an excellent and valuable account of most of the work done in relation to this organism.

Chap. vi. calls for little comment. The confusion which exists in regard to the bacteriology of influenza presents a difficult task to a writer on the subject, and Dr. Scott has done the very best with the material at his disposal. He has given the various views with great fairness, and though apparently he is a convinced believer in *B. influenza* (Pfeiffer) as a cause, he has not overemphasised the evidence in his favour.

The work by Prof. Hewlett in Chap. vii. gives all the necessary information on the various subjects dealt with in that chapter.

Taking the volume as a whole, we welcome it as a very valuable addition to the bacteriological library. It will be a constant source of reference to all workers on this group of organisms, and they will, we think, generally find some valuable information on any work they may be undertaking.

J. M. BEATTIE.

Tropical Agriculture.

A Text-Book of Tropical Agriculture. By Sir Henry Alford Nicholls. Revised by John Henry Holland. (Macmillan's Manuals for Students.) Second edition. Pp. xxxvi + 639. (London: Macmillan and Co., Ltd., 1929.) 15*s*.

WITH the need for the development of our resources in the tropical colonies brought so prominently before us in recent years, it is surprising that we have been so long without an up-to-date text-book on tropical agriculture. The want of such a book has long been felt; the reviewer has frequently been asked in recent years to recommend a suitable work of this character to intending settlers and for use in schools and colleges. The demand for the book is further indicated by the fact that Sir Henry Alford Nicholls's text-book, first published in 1892, was reprinted seven times at intervals of about five years. The subject of the present review is the second edition of the same work, which has been revised and partly rewritten by Mr. J. H. Holland, of the Museums staff of the Royal Botanic Gardens, Kew.

To deal with the several groups of subjects included under the general term 'tropical agriculture' is no easy task. To deal with them exhaustively would require a volume for each. The result would be a series of monographs, of which the complete set would not only be too bulky, and too costly for the planter, but it would also be so exhaustive that the average man would not find

time to wade through it, and it would be beyond the ability of the school or college teacher to sift out of this mass of information the facts essential for class-room lessons. It is true that a man who is about to undertake maize-growing on a large scale will be glad to have an exhaustive treatise on the subject, which he can consult from time to time as questions arise. But with the tendency toward reducing the risk of loss by the use of catch-crops, green-manure crops, and rotation crops, the tropical agriculturist would like to have some handy and not too detailed book of reference which will suggest to him crops which are, at any rate, worth experimental cultivation. The book before us is of this character. It is of handy size, limited to 639 pages, well illustrated, with a convenient index in a single series and having the main points of the text indicated by marginal headings which enable one to find quickly the facts which are dealt with.

The text-book is divided into two parts, the first of which, comprising about 100 pages, deals with the elements of agriculture, grouped into thirteen chapters, namely, soils, plant-life, propagation of plants, climate (a bare couple of pages, which might have been enlarged with advantage), manures, rotation of crops (less than four pages; the result of experiments in the Dominions and Colonies, conducted during recent years, might have been recorded to good purpose), drainage, irrigation (here the information is limited to two pages and more might have been said), tillage operations, pruning, budding, and grafting.

The second part, comprising 510 pages, is divided into twenty chapters, dealing with such diverse subjects as coffee, cocoa, tea, sugar-cane, fruits, spices, tobacco, drugs, dyes and tans, tropical cereals, food-plants (for example, cassava, arrowroot, yams, pulses, etc.), fodder-plants, rubbers, fibres, oil-seeds, and volatile oils.

The paragraph on teff-grass (*Eragrostis abyssinica*), p. 465, might have been enlarged to advantage. More than a quarter of a million acres in the Union of South Africa are devoted to this grass as a hay crop, and its use has extended to Northern Rhodesia, Australia, and elsewhere. The value of the crop to South African farmers is placed at more than a million pounds sterling per annum. The very fine seed of the teff plant requires suitable handling if the crop is to succeed, and instructions as to seeding, etc., would have been helpful.

In view of the great importance of maize for stock food, for feeding native labour, and as a cash crop for export, a little more attention might have been given to it. Some of the information supplied could have been replaced to advantage by the results of more recent work in the Union of South Africa, in Rhodesia, in Kenya, and elsewhere. The writer speaks of 'yellow-dent' as a particular variety of maize, whereas it is a class-name which covers many varieties. It is misleading to speak (p. 405) of a rainfall of about "50-80" inches as "required" for maize; in some countries this proves far more than is good for the crop. The precipitation requirement will vary, of course, with the incidence of the rainfall, and the degree of evaporation and transpiration which, again, are affected by temperature. The Argentine maize-belt, which produces a large part of the world's supply, has an average rainfall ranging from 31·5 in. to 39·4 in. (see Burtt Davy, "Maize", pp. 37-42). In Rhodesia, Natal, and the Transvaal, a mean rainfall between 25 in. and 35 in. is the optimum for this crop.

In reading through the pages, one feels that the author of this revision must have been somewhat hampered by the fact that he was preparing a new edition of an old book. The changes which have taken place in agricultural practice, in the more than thirty-five years since the first edition appeared, due in part to increase in knowledge of the fundamental sciences and in part to experience, are so great, and such vast developments have taken place in the Dominions and Colonies in the period referred to, that it would have been better had the book been completely rewritten from cover to cover.

A very minor error, but one too frequently made, is the use of capital letters for the adjectival form of specific names of plants: for example, *Ledgeriana* and *Deeringiana* instead of *ledgeriana* and *deeringiana*. The use of capitals for *Litchi* and *Cavendishii* is correct, these being proper nouns in the nominative and genitive cases respectively. Owing to the difficulty which agriculturists, foresters, and horticulturists must necessarily have in ascertaining whether a word used as a specific name is entitled to a capital letter (on account of the fact that it has been used at one time as a generic name), it might possibly be better to decapitalise specific names throughout, in all technical publications intended for their use.

It is the duty of a reviewer to criticise. In doing so it is far from our desire to belittle a book for which we have long felt the need, and which can be confidently recommended to the would-be settler, the planter, and last, but by no means least, the teachers in schools and colleges who are endeavouring to arouse an interest among their students in the development of the British Empire overseas.

Our Bookshelf.

Elements of Optical Mineralogy: an Introduction to Microscopic Petrography. By N. H. Winchell and A. N. Winchell. Entirely rewritten and much enlarged by Prof. Alexander N. Winchell. Second edition. Part 3: *Determinative Tables.* Pp. xii + 204. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1929.) 22*s.* 6*d.* net.

THIS edition of Part 3 of Winchell's "Elements of Optical Mineralogy", now published separately, entirely supersedes the earlier edition, which was incorporated with Parts 1 and 2 in one volume. Following a short introduction, five tables for the determination of minerals under the microscope are given. In the first a few of the commoner opaque and semi-opaque minerals are arranged with reference to their colour in reflected or transmitted light. No pretence is made, however, of dealing completely with this group. Minerals transparent in thin section are dealt with exhaustively in Tables 2 to 5. They are first listed with reference primarily to their birefringence. In Table 3 colour is the main determinative characteristic. Next come complete lists of isotropic and anisotropic minerals placed in the order of their refractive indices. In Table 5 the author has arranged the minerals in the order of their power of dispersion, so far as has been possible with the scanty data at present available. This is a useful addition to the methods of classification more usually adopted in determinative tables. Full explanatory notes precede each table.

There are also three plates, conveniently held in a pocket at the end of the book. Plate I. is a large coloured diagram showing the relationship between the interference colours of crystals, the thickness of the sections, and the birefringence of the crystals. Plate II. is a graphic representation of the most important minerals, based on their refringence, birefringence, and optic sign. It shows the variation in these properties resulting from variation of composition. The third plate is a copy of Wulff's stereographic plot for use in the study of minerals by the methods of the Federoff universal stage.

The volume is well produced, comprehensive, and up-to-date. It should prove useful to all engaged in the study of microscopic petrography.

The Acoustics of Orchestral Instruments and of the Organ. By Dr. E. G. Richardson. Pp. 158 (20 plates). (London: Edward Arnold and Co., 1929.) 10*s.* 6*d.* net.

DR. RICHARDSON has followed his recent "Text-Book of Sound" with an attractive book founded on the 1929 Martin White lectures given at the Northern Polytechnic, London. The subject of the lectures was the tone production of the organ and other wind instruments, and forms the basis of the first four chapters. Whilst the treatment is essentially popular, it includes much of the important work done since the time of Helmholtz. A special feature of the book is the profusion and excellence of the illustrations, which include not only all the various instruments discussed, but also Carrière's striking photographs of eddy formation in the production of edge tone, details of the remarkable Pleyel Hall in Paris, and vibration curves of Milner and Barton and Browning. It is unfortunate that all these curves are of necessity qualitative, since they were obtained with recording apparatus depending upon resonance in which the response was unequal and imperfectly known at the various frequencies.

No special chapter is devoted to the organ, which is "in itself an orchestra", but the scope of the book is extended in the later chapters to deal with percussion, the strings, and *ensemble.* It is a little difficult to understand why church bells are included and the pianoforte excluded. The modern composer uses the pianoforte, and in one work even the gramophone (to reproduce the song of the nightingale), as purely orchestral instruments. There is more detail of architectural acoustics than of the phenomena of hearing, which are equally important in considering the effects of an orchestra in action. Apart from an appendix on the theory of fingering and cross-fingering on the wood-wind, the book is free from mathematics and is therefore of wider appeal. The author has further elaborated some of the topics of his Cantor Lectures (*Jour. Roy. Soc. Arts,* **78**, January 1930). W. H. G.

The Scientific Fundamentals of Gravity Concentration. By Prof. Josef Finkey. Translated into German from the Hungarian by Prof. Johann Pocsubay. Translated from the German by C. O. Anderson and M. H. Griffiths. (Bulletin of the School of Mines and Metallurgy, University of Missouri, Technical Series, Vol. 11, No. 1.) Pp. 295. (Rolla, Mo.: School of Mines and Metallurgy, 1930.) 1 dollar.

PRIMARILY this work appears to have been written with the view of helping the mining engineer to understand more thoroughly the principles mentioned. Undoubtedly it will clear up many abstruse points for the practical engineer, but the strongly mathematical treatment makes it a work for the specialist, who will no doubt read it as it should be read, that is, in conjunction with the latest published accounts of experimental research on mineral dressing.

Descriptions of machines are not attempted, and the author makes it plain in his preface that it was his wish to treat those parts of the subject which are not adequately treated in the standard works. As it now appears in three languages, this may be taken as some measure of the merit of the work. After the introduction there are four chapters, of which the first deals with the mechanical principles of gravity concentration, and the subsequent chapters deal with the preparation of mineral or ore for concentration, jigging, and concentration on tables respectively.

It will be clear from the above that the scope of the work is limited to the treatment of ores and minerals in water. As is well known, there is a great number of processes in use for the dressing of minerals to-day in which water plays no part

at all, and others in which water is modified to give further benefits. That the latter class is not treated directly, is simply further proof of the special nature of the work. To the student the importance of the work will lie in its supplementary character, while the engineer in charge of a mineral dressing plant will find much new light thrown on the separation of mineral and gangue by water. C. H.

Winchester College Natural History Society. The British Palmate Orchids. By H. Cary Gilson. Pp. 36+35 plates. (Winchester: P. and G. Wells, Ltd., 1930.) 3*s*.

ALTHOUGH much valuable work on the British palmate orchids has appeared in recent years, notably by Dr. G. C. Druce and by the Rev. T. and Mr. T. A. Stephenson, this has been scattered among a number of papers in different journals. It is consequently difficult to find out the general conclusions which have been, or can be, drawn from such work, or even to tell what species are actually recognised as distinct.

Mr. Gilson has attempted in the little book under notice to bring together all this information and to sum up what seem to be the chief conclusions which can be derived. The descriptions of the species are very complete and clear, while full references are given to the sources of information. Each species is illustrated by photographs of the plant *in situ* and of individual flowers. These are good on the whole, but would be more useful if the scale of magnification were given in each case.

In the second part of the book the author describes his own studies on the group as represented in the neighbourhood of Winchester, describing a number of localities and the orchid populations growing there. The most interesting portion of this part of the work is Mr. Gilson's theory of the status and origin of the various forms of the polymorphic *Orchis latifolia* L. as found in Britain. This is very suggestive and is certainly worth following up. As Mr. Gilson properly points out, only definite experimental work can prove what is correct in this and other examples. It is, however, decidedly encouraging to see that this extremely difficult group of plants is being studied along ecological and genetical lines in conjunction with the more orthodox taxonomic methods; for it is only by such means that further progress can be made either in the orchids or in any other group of British plants. V. S. S.

Physical Measures of Growth and Nutrition. By Dr. Raymond Franzen. (School Health Research Monographs, No. 2.) Pp. xii+138. (New York: American Child Health Association, 1929.) 1 dollar; cloth, 1.25 dollars.

THIS monograph is a statistical study of anthropometrical data obtained from 10-12-year-old children: the work was carried out with the view of devising satisfactory methods of measurement of the state of nutrition of the subjects. No satisfactory agreement between different observers was obtained when only general estimates of nutritional condition were made; greatest agreement was reached between different estimates of the amount and quality of muscle and of subcutaneous tissue.

Certain of the conclusions given in the report may be mentioned to give an idea of the scope of the work; thus it was found that the correlation of height with weight is not nearly so high as that of other skeletal combinations with weight; individual differences in chest dimensions and hips are more important as determinants of variations in weight. Individual variations in weight depend on variations in certain easily determined bodily measurements, and can be almost wholly explained as due to these latter. The methods used and the results obtained are presented in great detail; the work is an important contribution to the determination of the characteristics of the 'normal' boy or girl and to the value of different methods of estimating this normal and the deviations from it.

Ethnography. By Prof. Loomis Havemeyer. Pp. vi+522. (Boston, New York, Chicago and London: Ginn and Co., 1929.) 21*s*. net.

THERE are few subjects in which the preparation of a text-book presents greater difficulties than ethnography, especially if for various reasons it is necessary to keep within a moderate compass. Prof. Havemeyer's "Ethnography" has been written with the special view of the significance of the facts for the development of social evolution. In order to avoid too great diffuseness on one hand, and, on the other, the effort to be encyclopædic, his plan has been to select a few tribes under the main races about which we know all the typical and significant facts on reliable authority, and then to describe them under the main aspects of their self-maintenance, self-perpetuation, self-gratification, religion, and regulative organisation. On this scheme the black, brown, red, yellow, and white races are described in turn; but the main groups of the yellow and white races are not touched upon for reasons of space, the description of the former being confined to Tibetans and Yakuts, and of the latter to Hindus.

Races of Africa. By Prof. C. G. Seligman. (The Home University Library of Modern Knowledge.) Pp. 256. (London: Thornton Butterworth, Ltd., 1930.) 2*s*. 6*d*. net.

PROF. SELIGMAN'S book on Africa is almost a *tour de force* in condensation. As an introduction to the study of African peoples and culture it will be of the greatest assistance to students. Apart from its value as a comprehensive, if brief, summary of the present state of our knowledge, it serves to bring home to the public how great are the gaps in our information to be made up before anything approaching certainty in our conclusions can be attained. As the author points out in his introductory chapter, there are still in Africa unsurveyed areas and uncharted tribes. In physical anthropology a beginning has scarcely been made in the anthropometric survey which is an essential condition of valid argument on the racial history and affinities of the African peoples.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Artificial Disintegration by α-Particles.

IT is commonly assumed that the process of artificial disintegration of an atomic nucleus by collision of an α-particle is due to the penetration of the α-particle into the nuclear system; the α-particle is captured and a proton is emitted.

On general grounds it seems possible that another process may also occur, the ejection of a proton without the capture of the α-particle.

Consider a nucleus with a potential field of the type shown in Fig. 1, where the potential barrier for the α-particle is given by the full line and that for the proton by the dotted line. Let the stable level on which the proton exists in the nucleus be $-E^\circ_p$ and the level on which the α-particle remains after capture be $-E^\circ_\alpha$.

If an α-particle of kinetic energy E_α penetrates into this nucleus and is captured, the energy of the proton emitted in the disintegration will be $E_p = E_\alpha + E^\circ_\alpha - E^\circ_p$, neglecting the small kinetic energy of the recoiling nucleus. If the nucleus disintegrates without capture of the α-particle, the initial kinetic energy of the α-particle will be distributed between the emitted

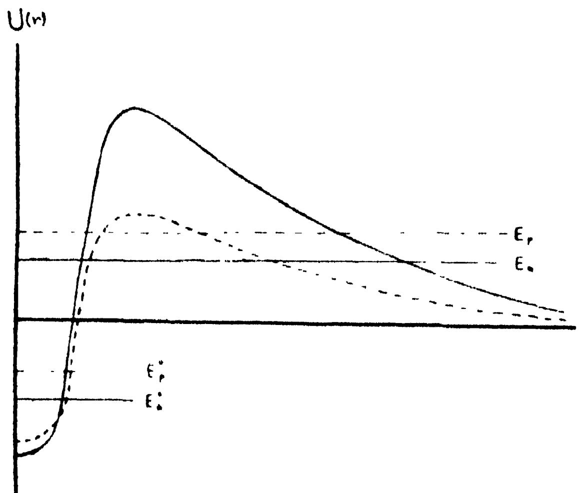

FIG. 1.

proton and the escaping α-particle (again neglecting the recoiling nucleus). The disintegration protons may have in this case any energy between $E_p = 0$ and $E_p = E_\alpha - E^\circ_p$.

Thus, if both these processes occur, the disintegration protons will consist of two groups: a continuous spectrum with a maximum energy less than that of the incident α-particles and a line spectrum with an energy greater or less than that of the original α-particles according as $E^\circ_\alpha > E^\circ_p$ or $E^\circ_\alpha < E^\circ_p$, but in either case considerably greater than the upper limit of the continuous spectrum (see Fig. 2).

In some experiments of one of us in collaboration with J. Constable and E. C. Pollard, the presence of these two groups of protons appears quite definitely in certain cases, for example, boron and aluminium. A full discussion of these and other cases of disintegration will be given elsewhere, but it may be noted that the existence of groups of protons has already been reported by Bothe and by Pose. In general the experimental results suggest that with incident α-particles of energy about 5×10^6 volts (α-particles of polonium) the process of non-capture is several times more frequent than the process of capture.

It is clear that, if our hypothesis is correct, accurate measurement of the upper limit of the continuous spectrum and of the line will allow us to estimate the values of the energy levels of the proton and α-particle

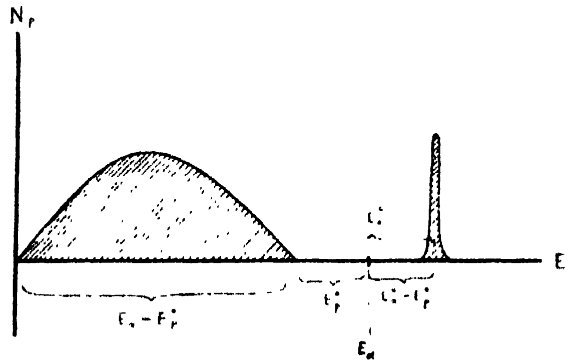

FIG. 2.

in the nucleus. In the case of aluminium bombarded by the α-particles of polonium the protons in the continuous spectrum have a maximum range of 32 cm. and those of the line spectrum a range of 64 cm. These measurements give the following approximate values for the energy levels:

$$E^\circ_p = 0{\cdot}6 \times 10^6 \, \epsilon \text{ volts, and } E^\circ_\alpha = 2 \times 10^6 \, \epsilon \text{ volts.}$$

On the wave mechanics the probability of disintegration of both types is given by the square of the integral

$$W = \iint f(r_{\alpha,p}) \cdot \psi_\alpha \cdot \psi_p \cdot \phi_\alpha \cdot \phi_p \cdot dV \cdot dV' \qquad (1)$$

where $f(r_{\alpha,p})$ is the potential energy of an α-particle and a proton at the distance $r_{\alpha,p}$ apart, and the wave functions ψ_α, ψ_p represent the solutions for the α-particle and proton before and ϕ_α, ϕ_p after the disintegration. In calculating the integral (1) we must develop the incident plane wave of the α-particle into spherical harmonics corresponding to different azimuthal quantum numbers of the α-particle, and deal with each term separately.

In the case of capture of the α-particle the estimation of (1) can be carried out quite simply. It can be shown that the effect of the higher harmonics is very small, and that the disintegration is due almost entirely to the direct collisions. Thus we obtain for the probability of disintegration

$$W_1^2 = \frac{A}{v_\alpha^2} \cdot e^{-\frac{8\pi^2e^2}{h}\cdot\frac{Z}{v_\alpha}} \cdot e^{-\frac{4\pi^2e^2}{h}\cdot\frac{Z}{v_p}}$$

where v_α and v_p are the velocities of the initial α-particle and the ejected proton respectively. Since only the first harmonic is important in disintegration of this type, it is to be expected that the protons will be distributed nearly uniformly in all directions.

When the α-particle is not captured the disintegrations will arise mainly from collisions in which the α-particle does not penetrate into the nucleus. For disintegration produced in this way the higher harmonics become of importance. The probability of disintegration can be roughly represented by the formula

$$W_2^2 = B \cdot e^{-\frac{8\pi^2e^2}{h}\cdot Z\left(\frac{1}{v'_\alpha} - \frac{1}{v_\alpha}\right)} \cdot e^{-\frac{4\pi^2e^2}{h}\cdot\frac{Z}{v_p}}$$

where v'_α is the velocity of the α-particle after the

collision, and B is a function of the angle of ejection of the proton. The protons of the continuous spectrum will not be emitted uniformly in all directions. According to the expression (3) the distribution with energy of the protons in the continuous spectrum will have a maximum value for an energy of ejection of about 0·3 of the upper limit, and will vanish for zero energy and at the upper limit.

More detailed accounts of the experimental results and of the theoretical calculations will be given shortly.

Cambridge, June 18.

Submarine Cable Interference.

DURING the summer of 1929 measurements were made on interference voltages received on a submarine cable in Trinity Bay, Newfoundland. The interference voltages were impressed on a vacuum tube amplifier capable of a power amplification of the order of 10^{15}. The amplifier and associated apparatus were designed to permit analysis of interference frequencies from 100 to 4000 c.p.s.

The usual types of natural as well as industrial interference were observed. The major part was of atmospheric origin, low frequency, low amplitude kicks being usually present, but at times masked by sharper and stronger static crashes and other types of interference.

During the three months over which tests were conducted, occasional comparisons were made between cable interference and audio frequency atmospherics applied to the amplifier by a large untuned loop. The two inputs were essentially the same regarding types of natural interference, but the higher frequency components of the former were considerably attenuated due to shielding effect of the sea water.

The level of natural interference was as a general rule low during daylight hours. During the evening a gradual increase of static kicks occurred, night level being reached some two hours after sunset. This level was usually held until the beginning of daybreak, when it dropped rapidly, usually reaching the day amplitude in less than thirty minutes. The highest levels of natural interference occurred during the last week of August and the first week of September.

In a few instances the interference in the intermediate frequency range (500 to 1500 cycles) increased considerably. By aural observation this interference appeared as a jumble of hollow rustling or roaring sounds. Another type of interference which often followed and sometimes accompanied periods of high intermediate frequency interference was characterised by swishing sounds, such as made by thin whips when lashed through the air. These 'swishes' were always found to vary in frequency, passing downward during some periods and at other times upward. At times the upward and downward progressions were observed simultaneously. The frequency range covered lay usually between 700 and 2000 cycles, but the individual tones usually did not cover a range of more than an octave. The duration of a 'swish' varied from possibly ½ second to more than a second. These two types of interference appeared to be independent of time of day or weather conditions. There is some evidence of correlation between them and periods of high magnetic disturbance. It is probable that the tones observed by Barkhausen[1] were the same as swishes of descending frequency. The musical atmospheric disturbances of descending tone described by Eckersley[2] may be of the same nature, although there are several notable points of distinction.

A type of interference frequently observed consisted of a damped oscillation of substantially constant frequency usually starting with a static kick. The audible duration was of the order of ⅛ second. The frequency range over which these oscillations could be expected extended from 1600 cycles to 2200 cycles. These oscillations, called 'tweeks' because of their characteristic sound, were observed on nearly all nights. They were never observed during daylight hours. They frequently appeared at dusk, at first very highly damped and spaced by intervals of several minutes. After nightfall the damping gradually decreased and the rate increased, the night conditions usually being reached in approximately one hour. The rate of occurrence during a night was usually between 3 and 30 per minute. Just previous to dawn the rate often increased for a few minutes, then decreased rapidly, reaching zero at the approach of full daylight.

Two independent series of tweeks were often observed, one of high amplitude and of frequency in the general region of 1700 cycles. The other was in the neighbourhood of 2000 cycles, of low amplitude very highly damped. The former often occurred in rapid trains. The latter were always observed singly. These two series of tweeks appeared to be entirely independent, often occurring at random during the same period. Frequent changes were observed in the frequencies of successive tweeks of both series, but the two were never observed to merge.

It is probable that electromagnetic disturbances resulting from static kicks could produce tweeks by multiple reflection between the earth's surface and a Heaviside layer. Considering the high amplitude tweeks, a reflecting layer height of 88 km. would correspond to a frequency of 1700 cycles. This is in fair agreement with Schelleng[3] and others as to the location of the low frequency reflecting layer.

The non-appearance of tweeks during daylight hours might be expected because of an ionised absorbing layer at low altitudes produced by the sun as described by Heising.[4]

The higher frequency tweeks, because of their higher damping, might be expected to originate under less favourable reflecting conditions. They may be produced in a higher latitude where the reflecting layer is lower, as suggested by Heising. They might even result from reflection between two Heaviside layers, the lower one being sufficiently poor in reflecting powers to permit passage of waves to the earth's surface.

Electron Diffraction by 'Forbidden' Planes.

SEVERAL experimenters have obtained results which they interpret as showing that electrons can be selectively reflected by crystal planes which would not give a corresponding Bragg reflection with X-rays, for example (100) in the first order for a face-centred cube. In some cases even 'half orders' of reflection are found. Thus in a recent paper[1] Rupp finds reflections from odd orders and half orders of the (100) cleavage plane of rocksalt, and similar face-centred cubic crystals. His experiments, like the others, were

made with electrons of the order of 100 volts energy, detected electrically.

I suggest that some of these extra reflections may be due to the Kikuchi lines, which are caused by diffuse scattering in the crystal followed by selective reflection. Using a single collector and varying angle or voltage, there is nothing to tell an experimenter whether a peak in his curve is caused by a Kikuchi line, or a Laue spot, falling on his collector. Some recent experiments which I have made to look for the half order effect show that the Kikuchi lines may be very prominent. If a piece of rocksalt is mounted so that the electrons, of about 30,000 volts, are incident on a cleavage face, a pattern of lines and spots is formed by the diffracted rays on a willemite screen (Fig. 1). If the crystal is

FIG. 1.—Diffraction by rocksalt The large spot shows the position of the beam with the crystal removed.

rotated about axes in, and perpendicular to, the cleavage face, the lines move rapidly over the screen and the spots flash in and out, forming a brilliant effect. I have measured the spots on the screen and photographed the whole pattern. Even quite complicated and unsymmetrical patterns, such as that reproduced, can be analysed and indices assigned to the planes which cause the various lines and spots, using the distances between the black and white Kikuchi lines to give the spacings. The angles between the lines are approximately those between the planes to which they are due, and this gives a useful check. In no case have I found it necessary to assume reflections from forbidden planes or orders. In an experiment, such as Rupp's, in which the crystal and collector are kept fixed and the voltage varied, the Kikuchi lines would move parallel to themselves. If one of them crossed the position of the collector a peak would be recorded. This event might or might not coincide with the appearance of a spot on the line at this point. If it does not, there will be a peak not explained on the simpler theory.

The measurements of the actual spots fit the simple theory approximately, but there is a slight compression perpendicular to the crystal surface such as might be caused by a refractive index. The corresponding inner potential would be about +10 volts, rather more than Rupp found. There is, however, always some charging up, and I am doubtful if one should regard the 10 volts as a true property of the rocksalt, or merely as an expression of the strength of the charge. Heating removes the charge, but also destroys the spots or greatly weakens them. Blue rocksalt is better than white, probably because of better conductivity.

A Physical Interpretation of Perturbations in Band Spectra.

THE interesting phenomena of predissociations and perturbations in band spectra are now attributed to interactions of various kinds between certain electronic states in the molecule. As has been shown, especially through a theoretical paper of Kronig (*Zeitsch. f. Physik*, **50**, 347; 1928), these phenomena may be considered from a common viewpoint, the characteristics of which are given below.

(1) Two interacting states, having equal energy, must also occupy equal values of J, the quantum number of the resultant angular momentum in the molecule.

(2) They must further belong to electronic states, of which the resultant orbital angular momenta (Λ) around the molecular axis agree within zero or one unit in $h/2\pi$.

(3) They must finally satisfy every kind of symmetry, to be questioned in cases of diatomic molecules.

Franck and Sponer interpret the predissociation phenomena in a very tangible way (*Göttinger Nachr.*, p. 241; 1928). A molecule, vibrating along the potential gradient a in Fig. 1, passes through the intersection P into a new state b. If the potential energy at P is greater than the dissociation energy of b ($W_P > W_b$), the molecule will predissociate through b, although being perhaps far below the dissociation limit of a. The conditions to be fulfilled are all included under section 2 and 3 in Kronig's theory above. Franck and Sponer emphasise the probability of the transition $a \rightarrow b$, when the intersection P is situated on the horizontal branch of b ($W_P = W_b$). Fig. 1 corresponds to a more general condition of predissociation, very recently proposed by Herzberg (*Zeitsch. f. Physik*, **61**, 604; 1930). From a wave mechanical viewpoint, predissociation

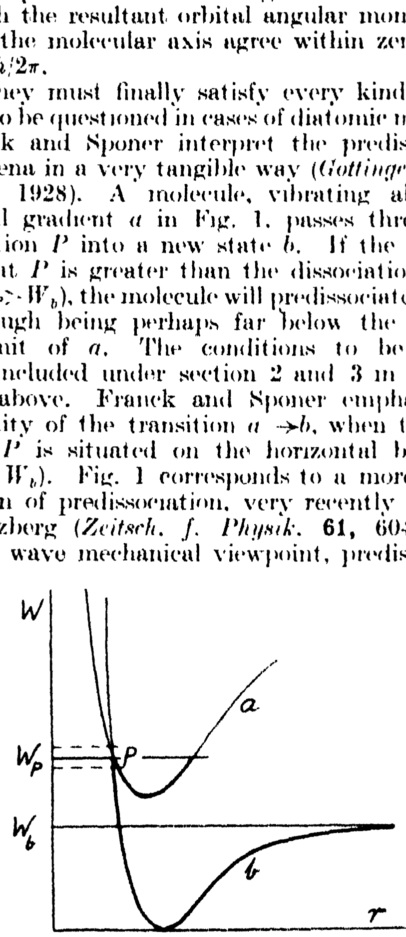

FIG. 1.

will take place even when the molecular energy not exactly agrees with W_P, as indicated by the dotted lines in Fig. 1.

Now, what happens when the intersection P falls below the limits of dissociation in a and b, as indicated in Fig. 2? Apparently the molecule will synchronise in a and b, and as both states now are quantised in discrete levels, all conditions in Kronig's theory have to be fulfilled. These conditions give an expression for the conservation of energy and the resultant angular momentum in the molecule. In addition, our viewpoint brings arguments on the conservation of the nuclear distance and the vibrational impulse during the act of transition in P.

A band series, emitted by raising the rotational energy of the molecule performing an electronic transitions $a \rightarrow c$, will exhibit perturbations in frequency as well as in intensity for lines corresponding to the region of intersection at P. An exact determination of P affords, of course, the construction of

a potential gradient $V_J(r)$, resulting from the rotation and nuclear vibration in the molecule (O. Oldenberg, *Zeitsch. f. Physik*, **56**, 563; 1929). As shown by Kronig, the frequency perturbations in the band-lines will be of the characteristic 'resonans type', in agreement with empirical results, especially with those of Rosenthal and Jenkins on the spectra of CN and CO (*Proc. Nat. Acad. Sci.*, **15**, 381; 1929; **15**, 896; 1929). The probability for the molecules penetrating the barrier between the potential gradients is essentially determined by the factor

$$\exp. - \frac{4\pi}{h}\int \sqrt{2\mu(V_J(r) - W)}dr$$

(Gurney and Condon, *Phys. Rev.*, **33**, 127; 1929). There will thus be a decrease of intensity in the perturbed region of the band series, due to the 'leaking through'

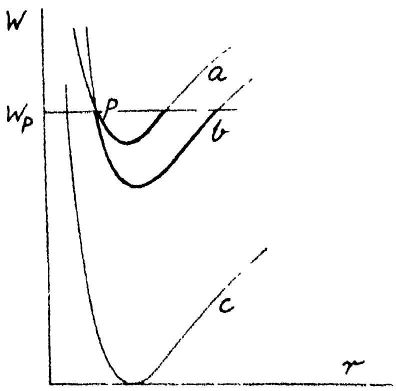

FIG. 2.

of molecules from a to b. This is a feature of many perturbations observed, and it seems not unlikely that a careful examination of their intensity distributions would admit a determination of the angular intersections at P. On the other hand, transitions $b \rightarrow c$ are allowed in cases obeying the emission rules (Δv 0, 1), and consequently, if our interpretation is correct, sporadic lines belonging to this system will appear in the perturbed region of the system $a \rightarrow c$ although the intensity maximum of $b \rightarrow c$ may be situated far away in spectrum. In fact, there are numerous perturbations in band spectra which exhibit a large, unsymmetric splitting of lines into two components, which may be interpreted in this way. In certain cases these conditions should also give rise to unequal perturbations in the P and R branches.

The main purpose of this note is to point out that Kronig's arguments can be graphically illustrated, and that this immediately requires further arguments for the appearance of perturbations in band spectra. As a matter of fact, there are cases known where no perturbations appear, although they might be expected to occur by Kronig's theory.

Variations with Sidereal Time in the Intensity of the Cosmic Ultra-Radiation.

PRELIMINARY results of measurements on the cosmic ultra-radiation, or the so-called highly penetrating radiation, as carried out by me using a Kolhörster ionisation chamber in Abisko in Northern Sweden (N. lat. 68° 21′, 388 metres above sea-level), have been reported in *Lund Meddelanden*, No. 121. The chamber is placed in an iron shield of 11 cm. floor-thickness and 6 cm. wall-thickness, and the opening upwards free. During the period Nov. 13, 1929 – Jan. 13, 1930, the chamber was observed every second hour except during the nights between 24^h and 6^h M.E.T. approximately. Later on, a photographic recording cylinder was placed in front of the microscope of the chamber, and the observations have been performed day and night in connexion with—as before—meteorological, magnetic, and auroral routine work.

The derived values of the intensity of the ultra-radiation as reduced to 760 mm. air pressure have been grouped according to sidereal time, and the mean values for every sidereal hour in fortnightly intervals are shown in Fig. 1, night-part dotted. The curves show considerable changes in their shape, as also in the case with the curves of G. Hoffmann and F. Lindholm as reproduced in *Gerlands Beiträge zur Geophysik*, **20**, 12, 1928, and **22**, 141, 1929. The means for the total period, however, and especially the means for the period Nov. 13–Dec. 16, 1929, agree essentially with the curves showing variation with sidereal time, deduced from the measurements of W. Kolhörster, G. v. Salis, K. Büttner, and E. Steinke (compare, for example, Corlin, *Zeitschrift für Physik*, **50**, 808; 1928; and Steinke, *Physikalische Zeitschrift*, **30**, 767; 1929). Only the maximum at 0^h sidereal time in the measurements of these authors is missing,

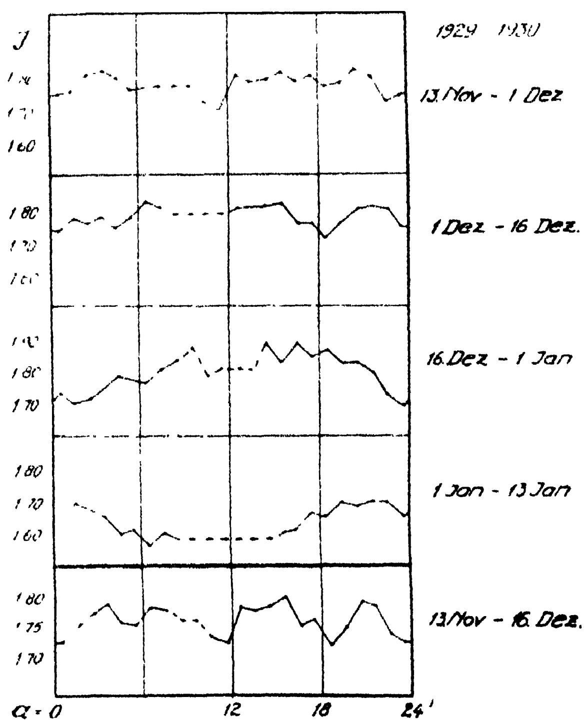

FIG. 1.

which may be caused by the difference in latitude of the places of observation. It is concluded that the daily sidereal curve of the cosmic ultra-radiation can present a very different shape for short intervals of time, but that there is a certain characteristic curve which always appears in the means for longer periods. This curve exhibits principal maxima for 0^h (except possibly for high northern latitudes), 6^h, 12^h–16^h, 20^h–21^h, and principal minima between 8^h and 12^h and for 18^h–19^h sidereal time.

The measurements of F. Lindholm also show the existence of this underlying characteristic curve, in spite of the very different shape of the curves for different months found by him (*Gerl. Beitr.*, **22**, 141; 1929). Thus, by taking the means of the three curves, termed "offen" in Fig. 3 of that paper, the upper

curve of our Fig. 2 is obtained. For comparison, the sidereal curve from the measurements of E. Steinke obtained in November 1926 with the same type of apparatus is shown in Fig. 2 (cf. also *Zeitschrift für Physik*, **50**, 808, and *Phys. Zeit.*, **30**, 767). It may be emphasised that at present no single set of hourly measurements carried out with allowance for the earth radiation and the air pressure, and with no shield covering the apparatus, has been published without showing this characteristic sidereal curve in the average values for a sufficiently long period. The

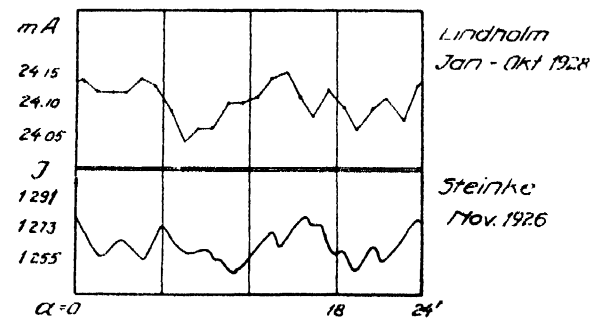

FIG. 2.

existence of a characteristic sidereal curve for the cosmic ultra-radiation seems thus to be definitely proved also. If so, it follows as an important consequence that there exist definite radiation centres among the heavenly bodies.

If there exist a correlation between the intensity of the cosmic ultra-radiation at a particular place and magnetic disturbances, which is now under investigation in Abisko, we look for the radiation centres in other directions than those which directly correspond to the sidereal times in question, and this may be carried out with the help of Carl Störmer's equations.

Raman Effect of Nitric Acid in Solution.

IN a recent publication (*Proc. Roy. Soc.*, **127**, 279; 1930; see also NATURE, **124**, p. 762; 1929) Ramakrishna Rao has shown how the Raman effect can be applied, in the case of nitric acid in solution, to demonstrate the increase of ionisation with dilution. In repeating his experiments I have obtained plates which, while confirming Rao's main conclusion, contradict some of his results.

In agreement with Rao, I find that the lines with $\Delta\nu \sim 1050$ cm.$^{-1}$ show the following peculiar behaviour upon dilution. Starting with 65 per cent acid and using the same exposure in each case, the intensity increases at first as the acid concentration is reduced, passes through a maximum, and afterwards falls off again. As was pointed out by Rao, this is doubtless due to the increase in the degree of ionisation with dilution, the lines in question belonging to the nitrate ion. Now Rao supposes that the wave-number shifts $\Delta\nu \sim 623$ and 673 cm.$^{-1}$ (given by him as 638 and 685 cm.$^{-1}$ respectively) also belong to the ion. If this be true, the corresponding lines ought to show upon dilution the same type of intensity variation as do those with $\Delta\nu = 1050$ cm.$^{-1}$. From my plates and photometer curves, however, it can be seen that this is not the case. The pair of lines with $\Delta\nu = 623$ and 673 cm.$^{-1}$ shows in fact a continuous decrease in intensity with dilution, and indeed disappears at a concentration where the lines with $\Delta\nu = 1050$ cm.$^{-1}$ are at their strongest. This behaviour is exactly parallel to that of the lines belonging to the non-ionised HNO_3 molecule, to which therefore $\Delta\nu = 623$ and 673 cm.$^{-1}$ must be ascribed.

The reason for Rao's error in ascribing these shifts to the ion is probably as follows. At concentrations where the lines with $\Delta\nu = 1050$ cm.$^{-1}$ are near their maximum intensity, a new weak single line seems to make its appearance. It is excited by the 4358 A. mercury line with $\Delta\nu = 707$ cm.$^{-1}$ approximately. It lies at 4497 A. ($\pm$ 2 A.), that is, not very far from the pair of lines with $\Delta\nu = 623$ and 673 cm.$^{-1}$ (λ = 4480 and 4490 A. respectively); and it is possible that a confusion between them led Rao to mistake the behaviour of the pair. The continuous spectrum, which masks Rao's plates at these concentrations, seems in my case to be not nearly so strong.

In support of his ascribing of $\Delta\nu = 623$ and 673 cm.$^{-1}$ to the nitrate ion, Rao states further that these shifts also occur for a solution of sodium nitrate. I am unable, however, to observe them in this case. Instead I find (along with a continuous spectrum) a weak single line with $\Delta\nu = 717$ cm.$^{-1}$, in agreement with the observation of Dickenson and Dillon. This line is clearly the analogue of the line with $\Delta\nu = 707$ cm.$^{-1}$ found in nitric acid; they both have about the same intensity (relative to the corresponding $\Delta\nu = 1050$ cm.$^{-1}$). The frequency concerned must belong to the nitrate ion, for the same single line is also found for calcium nitrate solution. There is, on the other hand, no evidence in favour of ascribing $\Delta\nu = 623$ and 673 cm.$^{-1}$ to the nitrate ion.

Vegetable Oils as Fungicides.

SINCE 1914 the chemical and mycological departments of Wye College have collaborated in testing the fungicidal properties of spray fluids, especially those containing sulphur. In this work, accounts of which have been published from time to time, a special technique has been developed, by which it is possible to determine within narrow limits the action of the spray fluid upon the powdery mildew of the hop (*Sphaerotheca Humuli*). The method has recently been applied to the investigation of certain oil emulsions, in particular vegetable oils, which have been found to possess marked toxic properties towards this fungus. Whilst some of these oils, for example, rape oil, have been recommended for insecticidal purposes and are of practical use as solvents for such substances as pyrethrum extract, their value as fungicides does not hitherto seem to have been noticed.

In experiments in which 0·5 per cent soft soap was used as the emulsifier, the following oils (of commercial standard) proved completely fungicidal against the hop powdery mildew: olive oil, 0·5 per cent; sesame oil, 0·5 per cent; cottonseed oil, 0·5 per cent. Rape oil required a concentration of 2·0-3·0 per cent and castor oil at 2 per cent was non-fungicidal. In experiments with other emulsifiers indication was obtained that the type of emulsifier used had a pronounced effect upon the toxic properties of the spray.

The experiments in question have been carried out on plants in the greenhouse, and no injurious effects have been observed on the foliage with many of these vegetable oils when used at a comparatively high concentration.

It is intended to ascertain whether these vegetable oils have a protective as well as a direct fungicidal action.

Weekly Variation in the Intensity of Ultra-Violet Waves of Sunlight in an Industrial Town.

DAILY records of the intensity of the ultra-violet radiation were made in Huddersfield between 1925 and 1928 by the acetone methylene-blue method.[1] While as a quantitative method this only gives approximate values, comparisons may be made in a qualitative way. The figures obtained here have now been analysed for weekly variations. Since this is one of the very few so-called smoky towns in which such records have been taken, the results may be of wider interest.

The subjoined table shows the mean daily intensity

Season.		Mon.	Tue.	Wed.	Thu.	Fri.	Sat.
June–Aug.	3·6	3·0	3·1	3·2	3·2	3·1	3·4
Sept.–Nov.	1·2	0·8	0·9	1·0	0·9	1·1	1·1
Dec.–Feb.	0·5		0·4	0·6	0·4	0·4	0·3
Mar.–May	1·8	1·7	1·7	1·7	1·6	1·5	1·6
Annual mean	1·78	1·45	1·53	1·61	1·55	1·57	1·63

on each day in the week for the four seasons and also an annual mean. One 'degree' is approximately sufficient to produce a moderate erythema of a white skin. There is a fairly pronounced maximum intensity on Sunday in all seasons except winter, giving indication of the effect of smoke-screening. The loss on week-days in summer amounts to nearly 15 per cent. Actually it seems that industrial smoke may here be responsible for a greater loss than this: there is an increase in the output of smoke from domestic sources on Sundays which will effect a lowering of the Sunday excess of radiation by an amount not easily ascertainable. The fair constancy of the mid-week figures probably shows that the effect of purely meteorological changes has been mainly eliminated in the analysis.

A similar summary for a country station would form an interesting comparison.

Blood-Groups among Australian Merino Sheep.

IN this laboratory, from time to time, we come across an anti-sheep cell hæmolytic serum from rabbits which causes rapid agglutination and sedimentation of sheep red blood cells. This is undesirable from the serologist's point of view. A sample of such serum was recently tested against fifteen random samples of sheep cells, and the latter, on the basis of agglutinability, could be sharply divided into two groups. We do not, of course, regard this observation as original, but merely wish to stress its importance for serologists and especially also for commercial firms dealing in bacteriological laboratory material. It might be well to define the group to which belonged the red cell antigen used in preparing a given hæmolysin, two or more groups having been determined on the basis of response to immune agglutinin. Incidentally, we pursued the line suggested by the above observation, and found that there are at least two 'blood groups' amongst pure-bred Australian merino sheep.

Infra-Red Absorption Spectrum of Sulphur Dioxide.

DICKINSON and West (*Phys. Rev.*, **35**, 1126; 1930) have determined the Raman spectrum of sulphur dioxide; they obtained displacements of 524 (weak), 1146 (strong), and 1340 (medium) cm.$^{-1}$. We had already examined the infra-red absorption spectrum of sulphur dioxide between 2 μ and 20 μ with a Hilger *D*. 42 spectrometer, using quartz, fluorite, rocksalt, and sylvine prisms, and found bands at 2498, 2321, 1871 (very weak), 1355, 1152, and 606 cm.$^{-1}$; of these the band at 1355 cm.$^{-1}$ is most intense and seems to possess a complicated structure. The fundamental frequencies are probably $\nu_1 = 1355$, $\nu_2 = 1152$, and $\nu_3 = 606$ cm.$^{-1}$. The two larger frequencies are in good agreement with those deduced from the Raman spectrum, although the scattered line at 524 cm.$^{-1}$ agrees more closely with the difference between ν_2 and ν_3 ($1152 - 606 = 546$ cm.$^{-1}$) than with ν_3 itself. The other bands can be accounted for as combination- and over-tones.

Careful examination failed to reveal bands reported by Coblentz ("Investigations of Infra-Red Spectra", p. 52; 1905) at 3·18 and 10·4 μ.

A detailed account of the investigation will be published shortly.

Effect of Magnetic Fields on Dielectrics.

IN a paper by S. Whitehead on dipoles in relation to the anomalous properties of dielectrics (*Phil. Mag.*, May 1930) there is a slight reference to the effect of magnetic field on dielectrics, but no details of any experiments or results. Experiments which we have carried out show clearly that when a constant magnetic field is superimposed on a dielectric which is being subjected to an alternating electric stress, so that magnetic and electric fields are normal to one another, then the presence of the magnetic field causes a change in the power factor of the dielectric and hence in the losses occurring therein. The nature of the results indicates that the effect of the magnetic field is to decrease the power factor.

The Acquired Characters of *Alytes*.

IN reply to the letter of Dr. Walker on Alytes which appears in NATURE of June 14, he is right in saying that I assume that potentialities of growth are altered by the environment and that the result is handed on to succeeding generations. Proof that it is so exists and could be given in detail were not space in NATURE so precious. Przibram gave five or six such cases when he was in London two years ago.

Dr. Walker's alternative explanation is hard to follow, namely, that 'variations' (produced by chance ?) survive. The superstition that selection can call into existence something that was not previously there is hard to kill.

Applied Science in Conference and Display.

THERE has been an opportunity during June to take part in two scientific occasions in Germany, both of first rank significance. The Achema Exhibition, opened in Frankfort on June 10, which continued for a fortnight, was primarily a display of laboratory apparatus and all that pertains to the efficiency and well-being of the chemist in his laboratory. A side issue of a most comprehensive character was an exhibition of chemical plant. Concurrently with the exhibition, a meeting of the Verein Deutscher Chemiker was held in Frankfort, and afterwards other more specialised bodies of chemists were in congress there: the habit of centring such annual meetings round an exhibition seems to be spreading. The meeting of the V.D.C. was of course of purely German interest, but a considerable number of British chemists visited the exhibition.

There can never have been a more comprehensive show of aids to chemical manipulation: to one who remembers the then startling innovations provided in Emil Fischer's new laboratory in the Hessischestrasse, Berlin, in 1899 on its opening, the progress is as remarkable as that made in any other branch of chemistry, and one does not recollect before to have had an opportunity of seeing it all summarised as it were under one roof. Comment in detail is impossible and so we pass to the chemical plant section, where undoubtably one of the outstanding exhibits was that of Krupp, designed to show the progress made in the invention of special non-rusting steels or more properly iron. On the principle said to apply to good wine, this exhibit was largely left to speak for itself: it consisted not only of the steels themselves with explanatory literature of real value, but also of all kinds of utensils for the household and for industry, including chemical industry. The exhibit was made by Krupps in conjunction with well-known users of the special VA and VM steels, so that a complete picture was obtainable of the many applications which rustless iron now has. The initial difficulties in working it have been largely overcome, and it appears to be chiefly a question of price which prevents it from being almost universally employed. It should be mentioned that Krupps show household utensils of rustless iron in their own shops in the larger cities of Germany.

Of equal interest was the comprehensive exhibit of the famous Metallgesellschaft of Frankfort, who have not hitherto indicated so clearly in how many different fields they are active. As necessitated by the novelty and interest of the exhibits, a very large force of technical experts was in evidence and no visitor was able to complain of lack of attention. Perhaps the greatest interest was evidenced in the display of the Carbo-Union showing the manifold way in which the remarkable absorbent properties of active carbon are being utilised, as, for example, in the stripping of benzol from gas, the recovery of volatile solvents from air, even when very dilute, the purification of water, the dephenolising of effluent from coke ovens, etc. There only remains space to mention the extending use of alloys of silicon with aluminium, which appear to have an ever-widening scope of application as their metallurgy is being better understood. The exhibition was adequately and comfortably housed in permanent buildings such as most Continental towns possess and was regarded by exhibitors and visitors alike as a serious and important occasion.

A night's journey in a sleeper, and we were in Berlin for the Second World Power Congress, attended by nearly 4000 delegates from forty-eight or more countries. The Congress, or at least the official delegates, were welcomed in the Reichstag on the evening of Sunday, June 15, by the highest in the land, when the Earl of Derby, the retiring president, handed over the gong of his office to Dr. Oscar von Miller. The little ceremony was both dignified and imposing, and the human touch supplied by the good wishes for the success of Lord Derby duly bore fruit at Ascot.

The official opening took place the next morning in the Kroll Opera House, when, following a short musical introduction, an address of welcome was delivered by Dr. von Miller and responded to by the delegates of the various nationalities, Sir Charles Parsons speaking first on behalf of Great Britain. The speeches were necessarily written and spoken to the microphone, so that the meeting was entirely devoid of personality, oratory, or enthusiasm. At the end we were favoured with more music conducted by a man whose joy, delight, and enthusiasm in what he and his orchestra were giving us was a veritable treat to behold. We must take heed lest in allowing everyone in a large audience to hear what is said we so mechanise what they hear as to make it of no interest. At the subsequent technical meetings, held in two large halls, every seat was provided with earphones and a dial, enabling the hearer to listen either to the original paper or to its translation in either of the three languages—English, French, or German. This arrangement also was only a partial success, in that the effort to speak for the microphone largely destroyed the personality and hence the effect of the orator. At the instance, we believe, of the Americans, the speeches at the World Festival in the evening of June 18 were transmitted by wireless from San Francisco. However attractive the idea, the transmission proved not only inaudible, but also an absolute nuisance, and after a quarter of an hour's patience, the audience ignored it. We have emphasised the terrors of the microphone because we have experienced its devastating effects at banquets at home, where real oratory such as provided by Dr. Nicholas Murray Butler at a recent Pilgrims' gathering is too great a treat to be lightly abandoned to the radio mechanic.

At the technical meetings a very large number of papers were read, discussed, and available in type; but the real value of the meeting, as always, was the contacts made between workers in different lands with kindred interests. Outstanding, as always in Germany, was the official hospitality

Apart from the reception at the Reichstag, the Congress was entertained by Germany, by the State of Prussia, and by the town of Berlin, in addition to a gala night at the Opera and the usual public and private hospitality. Fortunately, the English delegation was not only the largest, but also most thoroughly representative in character, and it played an important part in the deliberations. It was all the more to be regretted that Mr. Dunlop, the prime mover in the Conference, was himself prevented by ill-health from being present.

Naturally, the opportunity was not lost to show the visitors at the great evening festival some of the modern tendencies of Germany. Chief amongst these is the outdoor movement with a minimum of clothing and the cultivation of physical fitness. Most charming displays were given by girls and by young men. Of extraordinary interest was the final display of representatives of the German States in their national costumes and dances: the subordination of Prussia and the accentuation of the Rhine, of the Franks, of the Bavarians, scarcely seemed accidental. The enthusiasm when the president joined his native Bavarians was a fitting climax to a most remarkable evening, which to the knowledgable gave much room for thought, both retrospective and prospective.

Members of the Congress were provided with a quite unusual amount of literature, much of it of a permanent nature, giving information as to the power projects of Germany and of Europe. We have become used to the amazing development of cheap electric power either from coal or from water in the United States or in Canada: what the Congress should bring home is that similar developments are taking place on the Continent. Cheap electricity can do so much for the needs and comfort of mankind that no country of the first rank can afford to let its citizens be without it—it should be available in every village, in very farmhouse, throughout the land, as will soon be the case in France; it should be possible to carry out every power operation on the farm and in the living house, as well as in the factory, by its aid. The presence of so many of our leading electricians at the Congress shows that they are alive to the problems, but we fear the country as a whole fails to realise how far behind Britain is in the use of electricity per capita. We have very little water power, but our engineers are at least capable of emulating the remarkable results achieved at Chicago, where something less than a pound and a half of coal per kilowatt hour is required.

It is often forgotten that the production of electric power is as much a water as a coal problem, about 400 tons of cooling water being required for every ton of coal burnt, so that suitable sites for very large stations are not always easy to find.

The scope of the Congress stretches of course far beyond electric power; the carbonisation of coal either at high or low temperatures; the problems of oil, its refining and cracking, all come within its scope. In the end the goal is the same, to turn the heat latent in coal or oil, lignite or peat, with the highest degree of efficiency into energy, into power. The transformation in early days was not an easy one and as represented in percentages highly inefficient. Amazing progress has been made in improving the efficiency; the World Power Congress can but accelerate this. E. F. ARMSTRONG.

Irregularities in the Annual Variation of Temperature in London.*

THE average temperature of London is lowest about the middle of January and highest towards the end of July, but in any one year the temperature rises and falls irregularly, and the coldest day may occur in February or March instead of January, the warmest in August or September instead of July. Even when thirty or forty years are combined, some of these irregularities remain, and it is an interesting question whether, as the record is extended, the curve of temperature will tend more and more to a smooth annual variation, or whether certain irregularities are inherent in the climate and will always remain. This question was first examined in detail for Britain by Alexander Buchan, who recorded his conclusions in 1869 as follows:

"Deductions from all observations hitherto made show that . . . there are certain periods more or less well defined, when the temperature, instead of rising, remains stationary or retrogrades; instead of falling, stops its downward course, or even rises; and at other times falls or rises respectively for a few days at a more accelerated speed than usual."

* Synopsis of a paper read at the Royal Meteorological Society on June 18, by Dr. C. E. P. Brooks and S. T. A. Mirrlees, with some references to the subsequent discussion.

Buchan picked out six cold and three warm periods, as follows:

Cold Periods.	*Warm Periods.*
1. February 7–14	1. July 12–15
2. April 11–14	2. August 12–15
3. May 9–14	3. December 3–14
4. June 29–July 4	
5. August 6–11	
6. November 6–13	

Buchan's work was based in the first place on data for Scotland about 1860, but his results have been tacitly assumed to apply over the whole of the British Isles, and the 'Buchan cold and warm spells' have attained some celebrity. A repetition of the investigation seemed to be called for, using a long series of records for London.

Daily means of temperature at Kew Observatory based on hourly readings were formed for the two nearly equal intervals 1871 to 1900 and 1901 to 1929. These showed many small irregularities, and as warm and cold 'spells' were being sought rather than individual days, it seemed advisable to smooth the data. This was done by forming overlapping five-day means, for example, January 1–5, 2–6, etc., each five-day mean being entered against the middle day. The two curves obtained

in this way were compared with a standard curve representing the generalised annual variation, which was obtained by harmonic analysis of the twelve monthly means; the first two terms, representing the annual and semi-annual waves, were found to be sufficient for this purpose. The results are shown in the main curves of Fig. 1.

This figure shows that the five-day means of temperature during both periods oscillate irregularly about the smooth curve, but in general keep rather close to it. In most months the irregularities in 1871–1900 are quite different from those in 1901–1929, showing that they represent temporary or 'accidental' abnormalities and not permanent features of the climate. In particular, the curves seem to show quite definitely that the 'Buchan cold spells' do not recur regularly in London. The first, February 7–14, is represented, it is true, by a marked dip in 1901–1929, but the curve for 1871–1900 during those days rises rapidly to a maximum. In April 11–14 and May 9–14 neither curve shows any abnormal feature. In June 29–July 4 the curve for 1901–1929 is low but rising steadily, while that for 1871–1900 is definitely high, indicating a warm rather than a cold spell. In August 6–11 both curves are rising steadily, and again in November 6–13 neither shows any special anomaly. The figure is rather more favourable to Buchan's warm spells, for though the third, December 3–14, is not supported, the first two fall on dates when both curves are definitely high. An examination of the average temperatures at Kew Observatory for 59 years therefore accords no support for any of Buchan's cold spells, but suggests that the first two warm spells may have been well founded.

Apart from this, the curves show several points of interest. In December and January the average temperature since 1901 has been about 2° F. above the average for 1871–1900, a difference associated with the prevalence of warm winters during the present century. The magnitude of this change is clearly brought out by the lower inset diagram, which shows the results of harmonic analysis of the two periods separately. Not only have recent winters been warmer, but also the generalised minimum has been displaced from early in January to the end of the month, while at the same time the generalised maximum has been retarded from the middle to the end of July and the annual range has decreased, all indications that the climate has become more oceanic. Again, in 1901–29 temperature rose very rapidly during the latter half of May, and on May 30 the curve reaches a level which is not found again until June 17, a truly remarkable feature to occur in the 29-year averages for a season during which temperature should be rising

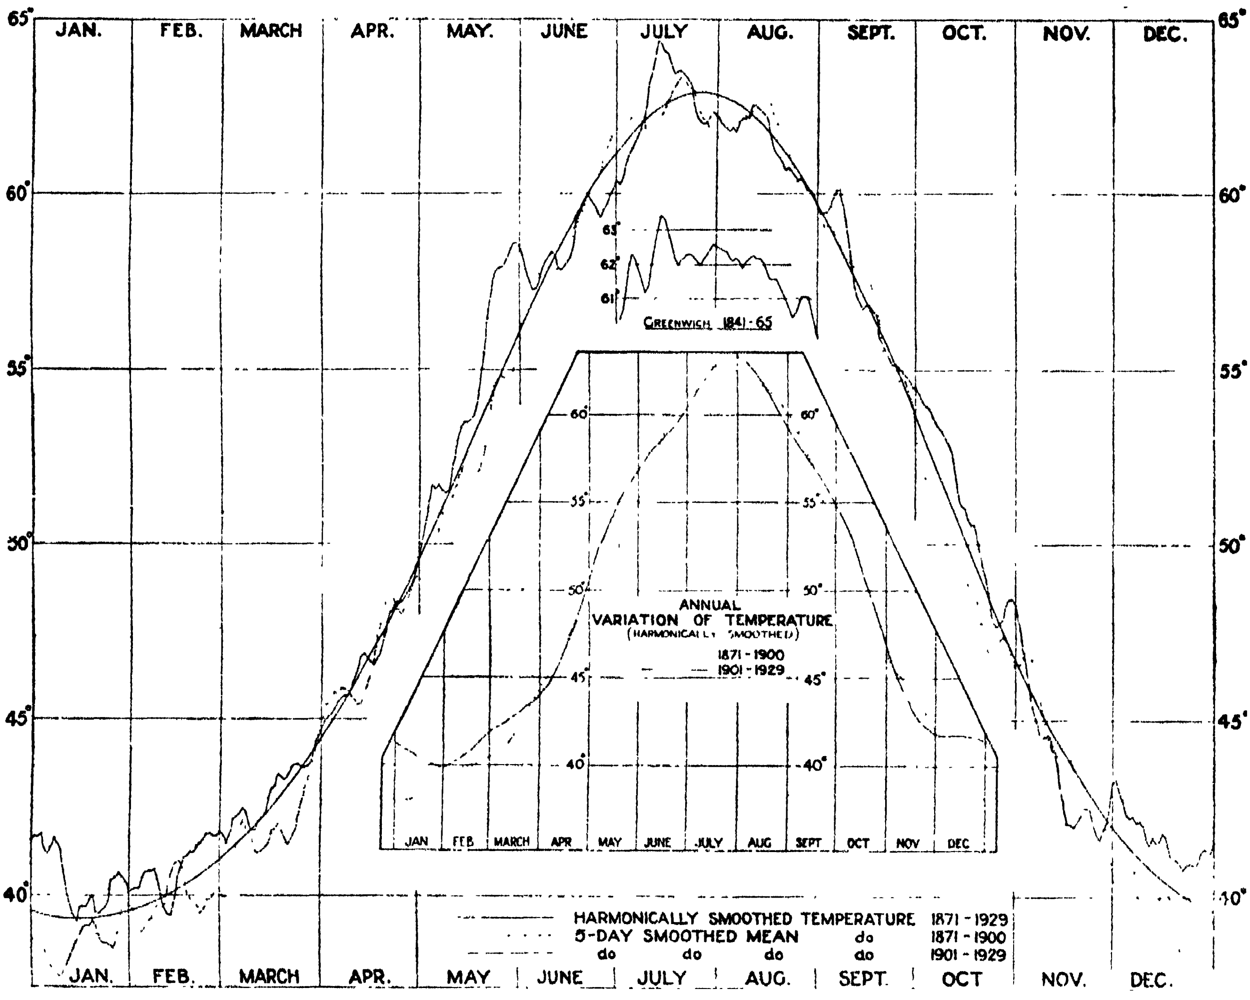

Fig. 1.—Temperature curves derived from Kew observations. (Reproduced by courtesy of the Royal Meteorological Society.)

steadily. A somewhat similar distortion, though less pronounced, occurs in early October, when the curve for 1901–29 shows a definite slackening of the autumn fall of temperature.

The third point of interest concerns the temperatures of high summer. Both curves show a marked swing, with a range of 2° F., from a maximum in mid-July to a minimum early in August and back to a second maximum in mid-August. This feature was of such interest that the five-day means of temperature at Greenwich during July and August were extracted for the period 1841–1865, and are shown in the upper inset of Fig. 1. Here the July maximum is again shown, but the minimum early in August does not appear and the August maximum is reduced to very small proportions. The impression left by a comparison of these three curves is that there is a definite tendency for a warm spell to occur in mid-July, after which there is a period during which temperature oscillates irregularly until the autumn fall sets in after the middle of August.

Although the comparison of curves showing averages over a number of years is the simplest method of approaching a problem of this nature, the results are sometimes misleading. The more interesting abnormalities revealed by Fig. 1 were accordingly studied year by year, in order to determine whether they are regular characteristics of the climate or whether they merely reflect a few outstanding events. In the first place the 'Buchan cold spells' in February, April, and May were examined to determine if there was any definite tendency for temperature in individual years to fall to minima on those dates. The results were entirely negative; the chance that one of these periods will be unseasonably cold is exactly equal to the chance that it will be unseasonably warm. If we allow a 'grace' of two days on either side, the individual curves show that temperature actually rose to a maximum more often than it fell to a minimum.

The warm period in mid-July affords an example of the fallacy sometimes introduced by reasoning from averages. During the whole 59 years the average temperature was highest on July 15–19, but when the individual years were examined, this predominance was found to rest entirely on four years, 1876, 1881, 1900, and 1921, while temperature was below the smooth curve on 30 occasions out of the remaining 55. The second crest on the curve occurs on August 14–18, and this period was abnormally warm on 32 occasions, cool on 27, a negligible difference.

The general conclusions drawn from the investigation were summed up as follows: "On the whole it seems improbable that there exists in our climate an abiding tendency for any part of the year to be either abnormally warm or abnormally cold for the season. It does seem, however, that such tendencies may spring up suddenly, persist for ten or twenty or thirty years, and as suddenly and mysteriously vanish. Any positive conclusions as to these spells are valid only for the time and place of their occurrence, and cannot be applied to other times or places. Thus, while Buchan's cold and warm spells were probably true for Scotland in the 1860's, they are certainly not true for London in the twentieth century."

In the discussion which followed the paper, Mr. D. Brunt objected that 'cold spells' were on some occasions limited to one or two days, and these would be masked by the use of five-day means. He also thought that the investigation should have dealt with individual years rather than with averages over long periods. It was suggested that a possible explanation of the persistent belief in Buchan's cold and warm spells was that when they did occur, they had a tendency to fall on or near Buchan's dates, though in many years they were absent. On the other hand, Mr. Mirrlees thought that the belief had persisted because meteorologists had devoted a great deal of effort to explaining the occurrence of such spells, and little or none to finding out whether there was anything to explain. Apart from this, a few of the explanations advanced were sufficiently plausible, for example, pressure changes set up by differential warming of the earth's surface, and outbreaks of polar ice, but as usually happens when theorising loses touch with facts, some of the theories were merely absurd. They included cosmic dust from meteor showers in the earth's atmosphere, cometary matter between the earth and the sun, the latent heat of freezing and thawing of Russian rivers, the varying absorption of radiation owing to changes of humidity, and *mirabile dictu*, the meteorological effects of newly expanded foliage in spring.

C. E. P. BROOKS.

Crime Statistics of England and Wales.

CRIMINAL statistics, apart from their primary purpose, usually afford some interesting sidelights on social habits and in particular on any changes which are taking place in the daily life of the community with which they deal. For example, in the criminal statistics of England and Wales for the year 1928 (Cmd. 3581, H.M. Stationery Office, price 4*s*. net) an attempt has been made to gauge the effect of the coming of the 'motor age' on crime. Taking the year 1928 and comparing the figures for the crime of 'breaking in' with those of 1911 it appears that, while the figures for the metropolitan area are practically stationary, in the home counties they show an increase of 437·8 per cent, and over the whole of England and Wales outside the metropolitan area the increase in boroughs and cities is 87 per cent, but in the counties it is 137 per cent. This is attributed to the increased use of the motor-car, which is thought to have acted in two ways. Greater numbers of the population have been enabled to live outside urban areas and premises are more often left unoccupied, while an increase in the 'all in' policy of insurance has tended to reduce precaution. On the other

hand, the burglar is also able to avail himself of the car and thus to travel with greater speed and further afield.

A preliminary analysis of the crime statistics in the return contains some interesting remarks relating to variations in the character and volume of crime. The quinquennium 1910 to 1914 is taken as a basis of comparison, as representing a normal average of criminality. Since this period the rise in population has been 9·26 per cent. and the normal rise in crime is therefore taken to be round about 9 per cent. Only figures over this percentage are taken as indicative of any real increase in crime. It may be noted in passing that both in the years after the Boer War and after the Great War there was a marked increase in criminality.

Taking the principal classes of crime, that is, indictable offences, as a whole the figures of 1928 show an increase of 33 per cent over those of 1910–1914. The highest increase in any individual class is under the head of offences against property with violence 80 per cent—while crime against the person increases by 22 per cent. Malicious injury to property falls by 57 per cent. But to bring out the significance of these figures a further analysis is necessary. Taking the class of offences against the person, these fall into two categories—sexual offences and offences generally of violence against the person. In the latter, after making allowance for the rise of 9 per cent, the only offence that shows an appreciable rise is that of procuring abortion. Such crimes as murder and attempts to murder, manslaughter, cruelty to children and child-stealing are among those that show a decrease. The net decrease over all is 4 per cent. In sexual crimes the greatest increase is in indecent assault and defilement of girls between 13 and 16. In the case of rape, defilement of very young girls, and in procuration and abduction there are decreases. Bigamy showed a very high figure—an increase of 120 per cent; but there is a decrease as compared with the period 1920–24. Offences between males increased.

In the class which shows the next greatest increase over 1910–14—crime against property with violence—a heavy increase in offences of 'breaking in', attempts at entering and being in possession of housebreaking tools far outweighs decreases in burglary and robbery. Reference has already been made to the motor-car as a factor in this section of crimes. It is to be noted in this connexion and also in connexion with certain other classes of crime, that the increase is in part due to the fact that a number of cases previously unreported are now brought to the notice of the police. For this the increase of insurance is to some extent responsible as such cases are now reported in order to obtain compensation.

Some interesting points are raised in an attempt to ascertain how far crime is affected by certain social factors, such as education, improved social conditions, and the old age pension, the after effects of war service, and the increased activity of women.

For the purpose of investigating the bearing of education on crime, the figures of 1928 are compared with those of 1882, when the results of the Education Acts of the 'seventies were beginning to bear fruit. It is sometimes said that the criminal now works with brains not brawn; but the figures in those classes of crime in which education is the primary requisite scarcely seem to bear this out. Since 1882 the population has increased by 50 per cent, but the increase in indictable offences is 30 per cent only. The incidence in offences against the person was about the same, but malicious injury to property and forgery and currency offences, the most likely to be affected by education, showed a decrease of 46 per cent and 3 per cent respectively. On the other hand, larceny of post letters increased; but this was owing in part to the immense increase in the volume of correspondence and the greater number of people handling the mails. Frauds also show a heavy increase, but this is a matter of recent years, and up to 1900 the figures show little variation.

Significant facts emerge in an examination of male age groups which bears upon the question of the effects of war experience and social conditions. The opinion is frequently expressed that war experience has led to a disregard to the rights of property and a disposition among war service men to take whatever is wanted and whenever it is wanted. But as a matter of fact the age groups in 1928 of those men who passed through the War compare very favourably with their seniors and juniors except in respect of obtaining by false pretences, frauds, etc. The group 21-30, however, which during the war would have ranged in age from 7 to 16, shows a relatively high rise in incidence of convictions and has obviously suffered from absence of parental control and other social conditions during the War. Again, the effect of improved social conditions and of the old age pension is seen in the older groups of 50 and over, where there is a fall in the incidence of convictions of 52 per cent.

As regards crime among women, the figures as a whole show that the increasing activities of women have not resulted in any serious rise in crime and have been accompanied by a great fall in the less serious and petty offences. Non-indictable offences have fallen 34·5 per cent, while the number of women has increased by 11 per cent. Cases of simple drunkenness have fallen from 12,219 to 5249, and aggravated drunkenness from 26,045 to 5489. Cases of cruelty to or neglect of children fell from 1424 to 362.

The figures for non-indictable offences present certain points of considerable social interest and significance. While there is an increase in less serious offences under Customs, Excise, and Inland Revenue laws, and a huge increase in motoring offences, proceedings for all offences denoting criminality or debased conditions of life have fallen considerably.

Studied comparatively, the statistics as a whole tend to show a more orderly and law-abiding population, living in improved social conditions. The most serious problem they reveal, as indicated by the incidence of crime in the age-groups, is that of the care and training of the adolescent.

Obituary.

MR. E. A. SPERRY.

THE death on June 16 of Mr. Elmer Ambrose Sperry, announced from New York, removes one of the best known of American inventors and electrical engineers and one who will always be remembered for his development of the gyroscopic compass and its application to all classes of vessels, including submarines, battleships, and passenger liners. But he did important work in many branches of engineering, and in 1925, when he was made an honorary doctor of science of the North-western University, Illinois, he was referred to as "an electrical engineer and a physicist who has shown remarkable skill in applying scientific methods and knowledge to the solution of practical problems; inventor of the Sperry gyro-compass; of many valuable aeronautic instruments; of the highest power searchlight; of fire control apparatus for the United States Navy; a pioneer electrical manufacturer in America; and a founder member of the Society of the American Institute of Electrical Engineers."

Mr. Sperry was sixty-nine years of age, having been born at Cortland, New York, on Oct. 12, 1860. Educated at the State Normal and Training School at Cortland and at Cornell University, at the age of twenty he founded the Sperry Electric Co. of Chicago. Electric arc lamps, electric mining machinery, and electric traction engaged his attention in turn, and he founded the Sperry Electric Railway Company of Cleveland, which in 1894 was bought by the General Electric Company of New York.

For the development of his invention, the gyro-compass, in 1910 he founded the Sperry Gyroscope Co., Brooklyn, and the following year fitted one of the compasses in the U.S. battleship *Delaware*. Subsequent inventions have added to the accuracy and the utility of his compass, and to-day ships are kept on their course day by day by the compass acting as helmsman.

Sperry's work was acknowledged by many societies, and in 1926 the engineering societies of the United States awarded him the medal which commemorates the work of the great iron-master John Fritz (1822–1913), among previous recipients of which have been Westinghouse, Noble, Edison, Kelvin, and Bell.

WE regret to announce the following deaths:

Mr. Victor Branford, editor of the *Sociological Review* and author of "Science and Sanctity" and other works on sociology, on June 22.

Mr. W. J. Greenstreet, editor of the *Mathematical Gazette* and honorary member of the Mathematical Association, on June 28, aged sixty-nine years.

Mr. C. E. Siebenthal, who was responsible for the annual reports on lead and zinc issued by the U.S. Geological Survey from 1907 until 1924, on Mar. 1, aged sixty years.

Prof. Frederick Slate, emeritus professor of physics in the University of California, known for his work on analytical mechanics, on Feb. 26, aged seventy-eight years.

Dr. W. E. Story, emeritus professor of mathematics at Clark University, fellow of the U.S. National Academy of Sciences and a vice-president in 1896 of the American Association for the Advancement of Science, on April 11, aged seventy-nine years.

News and Views.

IN his recent presidential address to the Institute of Mining and Metallurgy on "Periodical Variations in the Prices of Minerals and Metals", Mr. James G. Lawn pointed out that variations in the price of minerals and metals over short periods of years affect the mining engineer very closely and bring numerous difficulties in their train. Many efforts have been made, therefore, to secure the stabilisation of such prices, and this of necessity generally means control over supply, since the demand side cannot be so easily regulated. Sometimes, however, successful efforts have been made to stimulate demand; the most notable example being that of nickel. After the War the demand for nickel fell off rapidly, but as a result of research and propaganda, the producers were able to obtain the absorption of their whole output for commercial purposes and later on to increase considerably the consumption. Control over supply can sometimes be effected where known deposits capable of profitable working are limited in number and extent. In other cases, metallurgical difficulties in extracting a marketable product afford a basis for control. In the former category would fall diamonds, nickel, cobalt, potash, and nitrate, and in the latter, aluminium and magnesium. In the diamond mining industry, everyone connected with it, whether in South Africa, Congo Territory, Angola, or West Africa, recognises the necessity of control, and, despite many ups and downs in the trade, prices have been maintained for forty years. In the production of cobalt, an agreement between the producers in Ontario and Katanga to supply a half share each has maintained the price at 10s. per lb. Aluminium ores are plentiful, but since metallurgical treatment of the ores is costly the business is in comparatively few hands and control has been secured by agreement for some eighteen years.

IN his presidential address to the Devonshire Association on June 24, Mr. R. Hansworth Worth gave a detailed and stimulating account of the physical geography of Dartmoor. The address will appear in due course, with an admirable series of illustrations, in the *Trans. Devon Assoc.* for 1930. A good account is given of the vegetation of the moor and of its conversion into peat. It is shown that since the Early Bronze Age some two feet of peat have accumulated in the Erme valley. Decay is also going on, especially in the hill-top bogs, as for example in the ground around Cranmere Pool. From the coincidence of the planes of pseudo-bedding in the granite with the slopes of the hillsides and from other evidence, it is argued that the present topography of

Dartmoor is close to the original surface of the granite The china clay of the moor is referred to the action of vapours derived from the cooling granite-magma co-operating with meteoric water which obtained access to the granite surface through the then overlying cover of sedimentary rocks. Unusually wide partings in some of the tors are thought to be due to wedges of ice forcing the blocks apart when the climate was much colder than at present. The rock-fields known as 'clitters' are compared with similar erosional features in Spitzbergen, where they are probably due to hill-creep actuated by deep frost action. Rainfall and climate, rivers and border hills are given detailed treatment, and the address concludes with a brief survey of the geology of the area.

MR. WORTH protests against the methods of recent geologists who have "blazed a trail of unnecessary disfigurement across the whole face of the Moor". The perpetrators of this alleged damage may, perhaps, not unreasonably claim that their exertions have been amply justified by the harvest of results attained. Mr. Worth, however, does not refer to these beyond stating that he cannot accept the idea of differentiated types of varied age. He thinks that the intrusion of the granite took place in one operation. He also suggests that the attempt to make tectonic capital out of the direction of the joints is mistaken, since the joints are local in their origin and orientated in all directions He believes that the granite came into place as a wedge-like intrusion operating along the whole length of the axis from Dartmoor to the Scilly Isles, and that "there exists an elongated mass of granite, irregular in shape, isolated and self-sufficient, not fed by any lower reservoir through either necks or dykes, and that the upper protuberances of this mass now reach the surface and form the granite bosses of Devon and Cornwall".

ON July 1 a large party of archæologists began a four days' pilgrimage along the Roman Wall, assembling at Hexham, and proceeding along the whole 73 miles' length of the Wall from Wallsend-on-Tyne to Bowness-on-Solway in Cumberland. The expedition was organised by the Society of Antiquaries of Newcastle-on-Tyne and the Cumberland and Westmorland Antiquarian Society. A similar pilgrimage, but on a small scale, was made in 1920, and it is twenty-four years since a visitation of the extent and thoroughness of that of this year has been attempted. The first day's expedition covered the Wall from its eastern extremity to the Roman bridge at Chollerford, 21 miles west of Newcastle, when Mr. F. Gerald Simpson, Mr. Parker Brewis, and Mr. R. C. Bosanquet acted as guides. On the second day, Chesters (Cilurnum), the sixth fort on the Wall, and the museum with its remarkable collection of antiquities from the Wall were visited. Sir George Macdonald and Mr. R. G. Collingwood acted as guides. The second day's pilgrimage also extended to the great fort at Housesteads, to Peel, and to Chesterholme with its milestone. On Thursday Carlisle was reached after a journey of which the most notable feature was a visit to Birdoswald, where Mr. Richmond's excavations were examined in detail and the many problems raised by his work were thoroughly discussed. On Friday the pilgrimage came to an end at the seaboard. On Thursday, the party had received a large accession in numbers, in part, no doubt, owing to the attractions of the Birdoswald fort, but also without question owing to the fact that the itinerary for that day included the stretch of the Wall which is now threatened by quarrying operations.

ALTHOUGH the pilgrimage was independent of any movement in connexion with the attempt to save the Wall, we may expect with confidence that a visitation such as this will not fail to make its influence felt, both in the present issue and in formulating safeguards against similar vandalism in future. Apart from this possibility, the most striking feature of the pilgrimage was the way in which was brought out the great significance for Roman studies in Britain of the work of excavation and research in the neighbourhood of the Wall—notably at Cilurnum, Chesterholme, and Birdoswald—since the last occasion the Wall was visited.

THE annual exhibition, the eighth, of the antiquities obtained from Ur during the excavations of the past season by the Joint Expedition is now open at the British Museum. The exhibits, which are arranged in chronological order, are representative of every period of the city's history from the earliest to the latest times. The plans and drawings which illustrate the architecture of the temples, etc., at various periods are a revelation of the technical skill attained in Mesopotamia at this early age. Especially to be noted is the system of canals and walls discovered last winter, dating from about the time of Abraham. A photograph of a column of bricks from the temple ruins of the Third Dynasty (about 2300 B.C.) affords authentic evidence of the use of this architectural element at so early a date. The exhibits from the Royal City naturally take first place in interest and importance. A case of clay sealings is of particular significance, as it not only illustrates the early art and beginning of writing among the Sumerians, but it also provides material in the stratigraphical sequence of the sealings for fixing the dating of the Royal cemetery, which has been in dispute. A sectional drawing illustrates the sequence in the great pit in which were unearthed the remains of the city destroyed by the Flood. Cases contain reproductions of the actual graves in which lie the painted pottery side by side with the crushed skeletons. Above these cases is ranged pottery and clay figures from the graves and ruins below the flood level which illustrate the earliest art of Sumeria yet discovered, antedating by some centuries the magnificent wild boar carved in stone which was mentioned in Mr. Woolley's reports and is now exhibited here.

FROM the brief reports so far received, it would seem that the Indian earthquake of July 3 was much inferior to its great predecessor on June 12, 1897. Buildings were, indeed, damaged in many

places, some persons were injured by their fall, but as yet, though the earthquake occurred at 3 A.M., no loss of life is reported. In two sections of the Eastern Bengal Railway, bridges are unsafe and the lines are damaged. The centre of the earthquake is said to be at Gauhati on the Brahmaputra, about 320 miles north-east of Calcutta. As some slight damage was caused in that city, the shock must have been strong over an area of 300,000 square miles, and the disturbed area cannot be much, if at all, less than half a million square miles. That the shock should have been felt over so wide an area without attaining greatly destructive strength within it shows that the focus must be unusually deep. In his admirable memoir on the earthquake of 1897 (*Mem. Geol. Surv. India*, vol. 29, pp. 1-379; 1899), Mr. R. D. Oldham has outlined its epicentral area, and it is of some interest to note that Gauhati lies close to its eastern margin, showing that, after the lapse of nearly forty years, the centre of activity has shifted some fifty miles or more towards the east.

THE British Arctic Air Route Expedition sailed on July 6 in the *Quest* for East Greenland via the Faroes and Iceland under the leadership of Mr. H. G. Watkins. The main object of the expedition, as explained by the leader in an article in the *Times*, is to investigate the possibility of an air route across Greenland as a link in the route from London to Canada. This would be predominately a land line. No stretch of sea more than some three hundred miles would have to be crossed in one lap. The expedition is provided with two De Havilland Moth aeroplanes and fifty dogs and will be absent about a year, the *Quest* returning to Norway during the winter and leaving the fourteen explorers in Greenland. Journeys by dog sledge will be made on to the ice cap to north and south from a base about the Arctic Circle. Trial flights across to the west coast are contemplated. Perhaps the most important scientific aspect of the expedition will be the station which it is planned to found on the highest part of the ice cap for meteorological purposes. This will give the first winter observations from the interior of Greenland. Mr. Watkins thinks it not improbable that the best flying route across Greenland will be by the depression in the ice cap which seems to exist between about lat. 66° N. on the east and lat. 70° N. on the west. If this is so, air bases might be established in the vicinity of the settlements of Angmagsalik on the east and Disko on the west.

THE annual report of the Empire Marketing Board for the year 1929 has just been published (H.M. Stationery Office, price 1*s*.). Although the Board is of a non-political character, a change in government led to alterations in personnel, but it happily remains representative of all three parties. The experience during the past year has been most encouraging, and the outlook seems full of promise. The shipment of a number of Empire-grown foodstuffs into Great Britain in 1929 has in many cases surpassed all previous records, some such commodities being dried fruit from Australia, dairy produce and pork from New Zealand, fruit, sugar, and wines from South Africa, tea from India and Ceylon, and poultry from the Irish Free State. It is realised that no amount of good marketing will sell poor goods, and considerable attention is being devoted to the promotion of fundamental research work. Scientific investigations are being carried out both at home and overseas, the long lists of grants supplied for problems very varied in nature being evidence of the extent of the field under the auspices of the Board. The fullest co-operation has been, and is still being, sought between the Board and wholesale and retail traders. Encouraged by the goodwill already shown, and in order to utilise trade experience to the fullest advantage, a new main committee of the Empire Marketing Board has been appointed, to be known as the Marketing Committee. Its aim will be to secure a regular contact between itself and the complicated distribution system of Empire products among the consumers. The methods by which the Board attains publicity are many and various. Nearly two million leaflets were distributed during the past year, and the value of exhibitions, lectures, the cinema, etc. is becoming increasingly apparent. The publication of weekly intelligence notes giving full marketing information for fresh fruit and dairy produce has been extended, statistics of approximately ninety per cent of the butter held in cold storage now being included. In addition, statistical surveys of the world position as regards production and consumption of various foodstuffs are being issued.

The need for a closer co-operation between the breeder of domestic stock and the geneticist was the burden of Prof. F. A. E. Crew's address on "Genetical Methods of Livestock Improvement" to the Royal Society of Arts (*Jour. Roy. Soc. Arts*, May 16, 1930). He pointed to the difficulties of creating an ideal standard to which any breed should conform, since no single purpose could be imposed on any breed, independently of the fundamental necessities of healthy life and prolific breeding. The case of sheep was instanced as an example of the attempt by one set of interested persons, the manufacturers of wool, to set up a standard of fleece purity without reference to the primary purpose of the fleece as a protection for the sheep itself during the successive stages of its development. The geneticist is already in possession of a vast mass of knowledge of vital importance to the breeder, and although the breeder seems loth to take advantage of these facts, harmonious collaboration between the two is sure in the future to lead to the revisal and definition of standards, the analysis of excellence, the purification of stocks, and the removal of the menace of sterility. Prof. Crew looked forward to a time when added knowledge of the influence and working of the ductless glands would enable rate of growth, fertility, fat deposition, and so forth to be removed from the slow methods of selective breeding and to be controlled by the administration of the appropriate endocrine products prepared by the biochemist.

STREET traffic luminous signals have been widely adopted in many cities abroad and experiments with them are being made in many towns in Great Britain.

Many of the most efficient police officers in almost every country in the world are being used as semaphore machines, and the fatigue of continual arm movement must be considerable. As traffic supervisors they will probably always be required, but in our opinion considerable economies and higher efficiency could be obtained by the use of luminous signals. At many of the street crossings in Berlin there are conspicuous red, yellow, and green lamps visible to the traffic moving in one of the streets and simultaneously green, yellow, and red lamps visible from the other. Only one lamp is alight at the same time. The green and red mean proceed and stop, the yellow when it follows red indicates to the motorist or pedestrian that he is to get ready to proceed and when following green that he is to begin to stop. With one-way traffic in one street, as in the Unter den Linden in Berlin, this arrangement answers admirably. In the *Illuminating Engineer* for June there is an interesting paper on luminous traffic signals by T. Austin. He points out that the improvements made in glass moulding and in the production of coloured glass and the use of gas-filled electric lamps have immensely improved daylight colour signalling. For railway signalling, signal lamps can now be made which have a range of visibility of 4000 feet in bright sunshine. For street signalling economy can be effected by using automatic signals. When these are used, however, it will be necessary that motorists and others should be warned by a suitable sign when entering a district which uses them.

THE annual reports of the council and director of the Norman Lockyer Observatory for the year ended March 30 have just been issued. They show a very satisfactory year's work in spite of unfavourable weather conditions. Only 134 nights during the year were sufficiently clear for work to be done, and 124 of these were utilised. The Council considers, nevertheless, that at no observatory in Great Britain are the weather conditions more favourable for observation than they are on Salcombe Hill. The determination of spectroscopic parallaxes of early-type stars and the investigation of bright hydrogen line stars continue to form the main part of the work of the observatory. The equipment is about to be increased by a generous gift from Mr. Robert Mond, chairman of the observatory corporation, of an equatorial mounting for the Zeiss triplet lenses now in the possession of the observatory and a dome to house it. The work is in the hands of Messrs. Cooke, Troughton, and Simms, and is well under way. The Council remarks that if sufficient income were at its disposal, the observatory would be able, with present equipment, to keep another assistant or research student fully employed on valuable work. This, however, cannot be contemplated until further funds are available, and under existing conditions of depression in industry there seems little promise that the Council will be able to provide for any extension of the staff. During the year there has been a decrease of almost £160 in subscriptions and donations, but this has been offset by savings in salaries and maintenance and increased income from investments. The net result is a credit balance of £75 6*s*. 4*d*. carried to capital account as against £98 7*s*. 11*d*. in the previous year. A survey of the contents of the library has been undertaken, and shows that the observatory possesses a total of 5370 volumes and 7500 pamphlets, etc.

IN honour of the seventy-fifth birthday of Prof. Bohuslav Brauner, of the University of Prague, a special jubilee number (May–June) of the *Collection of Czechoslovak Chemical Communications* has been issued. This number contains more than twenty original contributions by friends and pupils of Prof. Brauner, together with a complete bibliography of his own original works and a lengthy account of his association with D. I. Mendeléeff. This communication is of unusual interest, since it makes available for English readers many fresh details concerning the varied and full life of the Russian savant, who died in 1907. From this intimate account of Mendeléeff's life and many-sided interests it becomes apparent how much he was indebted to Prof. Brauner for bringing his views and the periodic classification of the elements before Western men of science. Indeed, many of Prof. Brauner's earlier researches (for example, the proof that beryllium is a bivalent metal, the separation of didymium into praseodymium, neodymium, and samarium, and the attempted fractionation of iodine and of tellurium) were all directed towards the substantiation of the Periodic Law. Among the other contributions to this issue of *Collection* are three from Prof. J. Heyrovský and his collaborators, who continue the series of polarographic investigations with the dropping mercury cathode. These researches have now been in progress for ten years, and the method has been found of service in attacking problems in inorganic, physical, analytical, and now in organic chemistry. Prof. J. Štěrba-Böhm and Dr. Pisaříček describe certain new cerium compounds, particularly the double oxalates of the alkali metals with trivalent cerium. The existence of these compounds has revealed the cause of the difficulties encountered in attempting to precipitate cerium oxalate with alkali oxalates. Prof. B. N. Menšutkin and M. B. Wolff have also communicated a paper on the transformation of the cyclohexane ring into that of benzene.

IN the *Times* of July 1 reference is made to the recent purchase in London, by Dr. A. S. Rosenbach, the book dealer of Philadelphia, of a manuscript relating to the discovery of America. The manuscript is more than four hundred years old, and is thought to have been written by a friend of Columbus. Andreas Bernaldez, who was born about 1450 at Fuentos le Leon, Spain, and in 1488 was made curate of the village of Los Palacios near Seville and afterwards became chaplain to the Archbishop Diego de Deza, a friend of Columbus. When Columbus was on his way to the court of Ferdinand and Isabella to report on his second voyage he was the guest of Bernaldez, with whom Columbus left some of his writings. Until recently the manuscript, which is entitled "The Story of Christopher Columbus and the

ship in which he crossed the ocean until he discovered the Indies where they found gold" has lain disregarded in a Spanish library.

THE *Himalayan Journal*, the annual publication of the Himalayan Club, has made its second appearance. The current issue is full of well-illustrated articles on various aspects of mountaineering in the Himalayas. Lieut.-Col. H. W. Tobin reviews the history of exploration among the glaciers and peaks of the Sikkim Himalayas, and Lieut. J. B. P. Angwin gives an account of an expedition into the little known Kagan valley of the Kunhar River to the west of Kashmir. Several other articles treat of exploratory expeditions, and there is a useful account of the German attempt on Kangchenjunga in 1929. We note that among many spellings the Survey of India has adopted Kmchinjunga as the official spelling. In relation to the Shyok flood of last year, Major K. Mason discusses the likelihood of the Chong Kumdan glacier dam reforming and impounding another flood.

BARON GERARD JAKOB DE GEER, of Stockholm, and Prof. Tullio Levi-Civita of Rome, were elected foreign members of the Royal Society at a meeting of the Society on June 26.

HIS ROYAL HIGHNESS THE DUKE OF YORK has been elected an honorary member of the Royal Institution.

THE Bruce Prize of the Royal Society of Edinburgh for the period 1928–30 has been awarded to Mr. N. A. Mackintosh for his researches into the biology of whales in th waters of the Falkland Islands Dependencies. This prize is awarded by a Joint Committee consisting of representatives from the Royal Society of Edinburgh, the Royal Physical Society, and the Royal Scottish Geographical Society.

AT a meeting of the Royal Society of Edinburgh, held on July 7, the following were elected honorary fellows: *British Honorary Fellows*—Sir Arthur Stanley Eddington; Sir William Bate Hardy; Sir Arthur Keith; Prof. J. E. Marr; Prof. R. Robinson; Dr. D. H. Scott; *Foreign Honorary Fellows*—Prof. V. F. K. Bjerknes, Bergen; Prof. W. B. Cannon, Cambridge, U.S.A.; Prof. M. Caullery, Paris; Prof. G. Fano, Rome; Prof. E. H. O. Stensiö, Stockholm.

THE following appointments in the Colonial Agricultural Services have recently been made by the Secretary of State for the Colonies: Mr. W. J. Blackie, to be government chemist, Fiji; Mr. M. H. Grieve, to be assistant agricultural officer, Kenya; Mr. F. W. Thomas, to be district agricultural officer, Tanganyika Territory.

ARRANGEMENTS have been made with National Flying Services, Ltd., for the visit of a party to Hanworth Park on Wednesday, July 16, under the auspices of King Edward's Hospital Fund for London. Buses will be in readiness at Victoria Embankment (outside Charing Cross Underground Station) at 2.30 P.M. On arrival the visitors will be received by Capt. F. E. Guest, chairman of National Flying Services. Flying will be in progress during the afternoon, when all the latest types of light aeroplanes will be on view, and passenger flights will be available to visitors at a charge of 5s. Hanworth Park is the centre of private flying in Great Britain, and has been described as the most beautiful aerodrome in the world, as well as the most active civil flying training organisation. The estate was once a hunting-seat of Henry VIII. Tea will be obtainable on the club premises at a small charge. Application for tickets (price 10s.) should be made to the Secretary, King Edward's Hospital Fund for London, 7 Walbrook, E.C.4.

IT was decided at the International Congress of Orientalists held at Oxford in 1928 that the next meeting should take place in Holland. In accordance with that decision, preparations are now being made for the Congress to be held at Leyden on Sept. 7-12, 1931. Leyden was the place of meeting of the sixth Congress, which was held in 1883. An influential committee of organisation has been formed at Leyden, to which the preliminary arrangements have been entrusted. The secretary of the committee is J. H. Kramer, and the secretarial headquarters are at the Musée ethnographique, Rapenburg, 67, Leyden, to which inquiries and communications should be addressed.

WE have received a further notice of the second International Congress of Experimental Cytology, which is to be held at Amsterdam, on Aug. 4–9, in conjunction with the Anatomical Congress. As indicated by the preliminary programme, the questions discussed will relate mainly to problems which can be investigated by tissue culture methods. One symposium is concerned with the relations between blood and connective tissue, another with growth and differentiation in their reciprocal relations. Several of the papers will be illustrated by kinematograph film demonstrations. These include the function of osteoclasts, the phenomena of nerve stimulation, the functioning of heart muscle in tissue culture, and experiments on early chick and duck embryos. Papers will also be given on micro-dissection and other technical methods, and a discussion will be held on mitogenetic and other biological forms of radiation. Dr. Rhoda Erdmann will introduce a proposal to found an International Association of Experimental Cytology. Further information may be obtained from the Bureau of the Congress, 108 Sarphatistraat, Amsterdam.

AT the first ordinary meeting of the Microscopical Society of Wales, held on July 3, the biology of Roath Park, Cardiff, was discussed. Roath Park, through which a brook flows, has an area of more than 160 acres, and comprises a recreation ground, pleasure garden with bowling-greens and lawn-tennis courts, etc., a botanical garden, rock garden, flower and Cactus conservatories, lake, wild garden, and Llandennis gardens. As the largest park or open space in Cardiff it attracts many visitors. During the past two or three years, however, bathers using the lake have been affected by their skin being punctured, after which intense irritation sets in, and Roath Park Lake

has thus become a topic of conversation from a point of view other than that of its amenities. From the botanical point of view the park is notable amongst provincial parks and open spaces: the birds breeding in or frequenting it have been studied for about a quarter of a century, and many mammals have been recorded. As a field for microscopical study and research little has been done, but the meeting of the Society on July 3 directed attention to the many and varied interests which the park offers to microscopists. Although it is less than three months since the first move towards the formation of the Microscopical Society of Wales was made, its membership already exceeds a hundred, and the formation of local branches in other parts of Wales is under consideration.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: A research assistant at the Imperial Forestry Institute, University of Oxford—The Secretary, Imperial Forestry Institute, The University, Oxford (July 15). An assistant lecturer in botany in the University of Birmingham—The Secretary, The University, Birmingham (July 23). A lecturer in biology at the Cheshire School of Agriculture—The Principal, Cheshire School of Agriculture, Reaseheath, Nantwich (July 26). Five electrical inspectors of factories for inspection of factories and other places under the Factory Acts—The Industrial Division, Home Office, Whitehall, S.W.1 (July 28). A professor of biochemistry in the University of Liverpool—The Registrar, The University, Liverpool (Sept. 29). A junior assistant under the Directorate of Metallurgical Research of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S.E.18. A director of the Rubber Research Institute of Malaya; also a head of the botany division of the institute—The Secretary, London Advisory Committee, Rubber Research Institute of Malaya, 2 Idol Lane, Eastcheap, E.C.3. A temporary lecturer in biology or botany at Lincoln Training College—The Principal, Training College, Lincoln. A part-time lecturer in chemistry and experimental physics at Queen's College, London—The Secretary, 43 Harley Street, W.1. A lecturer in malignant disease in Aberdeen University and radium officer at the Aberdeen Royal Infirmary—The Secretary, The University, Aberdeen.

Our Astronomical Column.

The Spectrohelioscope.—Descriptions of the spectrohelioscope and of typical observations made with this instrument for solar research have been given by Dr. Hale in NATURE during the course of his experiments (**118**, Supplement, July 3, 1926, 1-8; **119**, 708-714; **121**, 676-680). A detailed account of the instrument is also given in the *Astrophysical Journal*, December 1929; and more recently, in the March issue, Dr. Hale describes some rapidly moving hydrogen flocculi which he has observed near sunspots—in particular several flocculi representing active prominences connected with a large group of sunspots from Sept. 16 to 26, 1926. The typical phenomenon described in the paper is a curved dark filament descending into the spot (either into the umbra itself or terminating at the edge of the penumbra as a small black head) with velocities of the order of 50 or even 100 km./sec. The bearing of those observations on the structure of the hydrogen vortices of the solar atmosphere is left for discussion in a future communication to the *Astrophysical Journal*. Photographs of rapidly changing flocculi are but seldom secured with the spectroheliograph—not that such flocculi are infrequent, but that their active phase appears to be usually of short duration, and so are usually missed at the time of exposure of the daily spectroheliogram. Moreover, high radial velocities pertaining to a flocculus would, owing to the Doppler effect, cause a displacement of the spectral line from the second slit of the spectroheliograph and so prevent, partially or entirely, the flocculus from being recorded. It is one of the ingenious features of Dr. Hale's design for his spectrohelioscope that flocculi with large radial velocities, especially differential velocities along their length, can be picked up and their velocities quickly measured by means of the 'line-shifter'.

The Planet Pluto.—The *Scientific American* for July contains an article by Prof. H. N. Russell describing Prof. P. Lowell's prediction of the elements of a trans-Neptunian planet and the search that has been carried on at the Lowell Observatory, resulting last January in the detection of Pluto.

Lowell's only notable error in predicting was his exaggeration of the mass and magnitude of the body. He assigned to it a mass 6 times that of the earth and a magnitude of 12-13. This error was responsible for the delay of 15 years before the prediction was verified. Instruments of insufficient light-grasp were used in the search until the president of Harvard (Prof. P. Lowell's brother) gave a specially rapid triple objective of 13 inches aperture. Mr. Tombaugh began a systematic search with this instrument about a year ago, and six months later he discovered Pluto.

Prof. Russell notes that Lowell's memoir (dated 1915) is now procured with difficulty. He therefore reproduces facsimiles of three pages of it. One is given as a specimen of the nature of the analysis; the other two are the final pages, giving a summary of the whole, and the elements of the two predicted orbits. The closeness of the prediction is shown by comparison of Lowell's first orbit with the following elements of Pluto deduced by Dr. A. C. D. Crommelin from the observations of 1919, 1927, 1930. This is practically identical with that given by Nicholson and Mayall using 1919, 1930, thus confirming the identity of the 1927 object with Pluto.

Perihelion Passage .	. 1991·2	1989 Jan. 15·8 U.T.
Longitude of Perihelion	. 205°	221° 44′ 1·0′
Asc. Node . .	. Not predicted	109 21 35·0
Inclination . .	. 10 (conjectural)	17 9 1·8
Eccentricity . .	. 0·202	0·2529548
Period . . .	. 282 y.	250·753 y.
Perihelion distance .	. 34·3	29·706
Computer . .	. Lowell (1915)	Crommelin

The close agreement in the four independent elements of date of perihelion, longitude of perihelion, eccentricity, and period is beyond what can reasonably be ascribed to chance. It is noteworthy that Prof. Russell's article was written before he knew of the 1919 and 1927 images: they have justified him in the estimate that he had already formed of the value of Lowell's work.

Research Items.

Monoliths in Assam.—Mr. J. P. Mills, and Mr. J. H. Hutton in vol. 25, No. 1, of the *Journal and Proceedings of the Asiatic Society of Bengal* describe a series of five groups of remarkable monoliths in the Cachar Hills not previously recorded in print. The monoliths are pear-shaped, artificially dressed, and each contains a cavity in the bulbous end. They are now recumbent, though they appear at one time to have been erected on their narrow ends. They fall into two distinct types which may be regarded as male and female. The former constitute the whole of a large group at Kartong, and a smaller group between Kartong and Kobak. Most of the stones are incised with geometric designs and forms of men and animals, such as the pig and the mithun. While the monoliths may be interpreted as embodying the phallic principle, assisting the fertilising of Nature, the hollows seem to have been meant for some specific purpose not easy to discern. It may be that they were intended to hold water to promote rainfall, or they may have been intended to contain offerings on the analogy of holes recently scooped out in ancient monoliths at Kasomari. It is concluded that the North Cachar hollowed monoliths must be regarded as a specialised development of a phallic ancestral cult typical of Assam. It is clear that they were not erected by the Nagas and old Kukis who are the present inhabitants of the area. Local tradition assigns them to the Mikirs. This may be the case, subsequent invasion having overwhelmed the Mikirs and left them in isolated communities too weak to provide the labour requisite to carry on the custom. It is more probable, however, that it is to be associated with the Khasi Synteng group of tribes and that it has disappeared owing to their migration into an unsuitable environment.

Tasmanian Crania.—Dr. W. L. Crowther describes in the *Papers and Proceedings of the Royal Society of Tasmania* for 1929 two crania (immature) of the extinct Tasmanian race. Immature crania of the Tasmanians are comparatively rare. Of these two, Skull *A*, that of a child of seven years of age, was found in 1908 by the author and Dr. Inglis Clark at Oyster Creek. It was in a cemetery near the Government Station where the last thirty or forty of the race were buried and was at least sixty years old. Skull *B*, that of a child 7-12 years old, was found by Mrs. Legge on the west coast in 1927. No trace of any other human bones was found with it, and the mandible was missing. Skull *A* from its fragility was judged to be female. Rings of short bronze-coloured hair still adhered to the scalp. Posthumous distortion of the left side was probably due to the body having been laid on that side. The glabella is not prominent. The orbits are almost equal in height and breadth, markedly contrasting with those of the adult. The mandible is in position and the face shows marked prognathism. The six-year molar is erupted and the twelve-year molars are *in situ*. Skull *B*, probably male, shows little or no prominence of the glabella and supra-ciliary ridges. The supra-orbital notch is wide and shallow. The nasal bones are not projected forward and upward as is seen in the adult. The orbits again are almost equal in height and breadth. There is no suggestion of the heavy overhanging eyebrows of the adult. The face is not so prognathous as Skull *A*. The vault of the skull is flattened rather than of the typical carinate form. Generally, both the skulls conform to the adult type and could be distinguished by their Tasmanian characteristics; but in both the typical carination is absent. In early life it appears that the marked width of the face at the expense of its height is not pronounced. The orbit and nasal apertures appear to expand laterally as the result of growth and mastication, and with the normal heavy development of the glabella and supra-orbital ridges give rise to the facial characteristics of the adult skull.

Growth Rate of Young Gorilla.—Dr. C. V. Noback is reported to have made a study of the development of a young gorilla received at the New York Zoo some time ago (Science Service, Washington, D.C.). He found that it grew more slowly than a boy of the same age, the rate of growth during the first three years of life being measured in terms of adult weight. But the bones and teeth matured more rapidly than those of a human child, for the full set of milk-teeth was developed at approximately eighteen months, and the permanent teeth began to be acquired at the age of two and a half years. The study will be reported in full in the *American Journal of Physical Anthropology*.

The Swallowing of Feathers by Grebes.—It has often been observed that different species of grebes contain quantities of their own feathers in their stomachs, and the frequency of this curious habit suggests that it has some functional significance. Mewes thinks that the purpose is to protect the lining of the stomach from abrasion, Biedermann that the feathers perform a function similar to that of pebbles in granivorous birds. Neither of these suggestions is altogether acceptable, and Dr. Josef Jirsík has made a new attempt to solve the problem (*Bull. de l'école supér. d'agronomie Brno, ČSR.*, 1929, Sign. D. 15). He found a young great-crested grebe (*Podiceps cristatus*) only a few hours old to contain 13 feathers, and another of the same brood 93, all the feathers having been plucked from the mother—an instinct apparently present at birth. The young birds began to swallow their own feathers as soon as they appeared amongst the down, and the adults took their own or each other's feathers almost indiscriminately throughout the whole year. Further, when the stomachs contained only small insects feathers were few, when fishes had been devoured they were many; so that the quantity of feathers seems to be regulated by the quantity of food swallowed. Hard and indigestible fragments of food were surrounded in the stomach by feathers, and the actual observation, made by means of a powerful binocular telescope, of vomiting movements on the part of the grebes similar to those of herons, strongly suggests that the feathers enable the birds to reject, in the form of a cast, the indigestible portions of a meal. Here apparently is a close analogy to the swallowing of fur by owls and other birds of prey.

Conditioned Responses in Fishes.—Mr. H. O. Bull (*Jour. Mar. Biol. Assoc.*, N.S., vol. 16, No. 2, 1930) has published the results of his further work on the capacity of fishes to form conditioned responses towards definite stimuli. He found that the wrasse is able to form stable conditioned motor responses to the note of a tuning-fork sounding the note lower *C* or to an electric buzzer giving a note approximately *F* in the second octave, when either was used singly. The fish was, however, unable to discriminate between them as sounds when both were used simultaneously but differentiated them by their position. The author was also able to build up conditioned responses involving visual stimuli in the plaice, cod, and coalfish. Two species of *Blennius* were able to form stable conditioned responses towards gustatory stimuli, such as sea water extracts of natural food substances, but

did not respond to an artificial olfactory stimulus such as artificial musk. The author concludes, as a result of his series of experiments, that the essential similarity between the responses built up in fishes and the conditioned reflexes in dogs becomes more emphasised as the data accumulate.

Young Stages of *Conus*.—The apex of *Conus* is not commonly found in a good state of preservation, while complete immature individuals are rare and that of *Conus adversarius* Conrad has hitherto been unknown. Mr. Burnett Smith is now fortunately able to describe and figure three specimens (*Proc. Acad. Nat. Sci. Philad.*, vol. 81). In the youngest of these a slight yet definite constriction serves to distinguish the whorl proper from the anterior canal, and this the author considers to be a significant suggestion of a pleurotomoid ancestry for the genus *Conus*.

South American Fish Poisons.—Messrs. E. P. Killip, of the U.S. National Museum, and A. C. Smith, of the New York Botanical Garden, in a botanical exploration of Peru and Brazil, paid attention to the plants used by the natives as sources of fish poisons, as such plants are possible sources of new insecticides. The most successful fish poison appears to be prepared from the roots of a plant which was frequently cultivated on this account and, curiously enough, was never seen anywhere in flower or fruit. They identify this plant as *Lonchocarpus nicou* (Aubl.) DC. after comparison with the specimen in the British Museum (Natural History). Two other species of this genus are also described as sources of fish poisons: one species from the lower Amazon River with an exceptionally powerful poison they decide is new and describe under the name of *L. urucu*.

Virus Diseases of Plants.—Henderson Smith summarises the literature on two obscure problems connected with virus diseases of plants in *Biological Reviews*, vol. 5, April 1930. The spread of the virus from the point of inoculation can take place from cell to cell, but the rate of spread seems high for such a process though low for transport in the water stream; Henderson Smith concludes that transport is probably mainly effected by the phloem. He also discusses the abnormal inclusions, the *X* bodies, characteristic of many virus-infected plants. He points out that some recent observations (F. M. L. Sheffield and Henderson Smith, NATURE, Feb. 8, p. 200) support the more commonly accepted view that these bodies are not living organisms, but a reaction product of the cell to the virus irritant.

Soil Formations in the Tropics.—Researches in recent years have shown that in mature stages of soil formation the characteristics of the parent material are obliterated and the soils are expressions of climate irrespective of origin. A low temperature with rainfall greater than evaporation and constant bleaching by cool water leads to a podsolised soil or podsol of a light colour and high silica content. Podsol is typical in Canada and northern Europe. In order to investigate its occurrence in high altitudes in the tropics, Mr. M. W. Senstius explored soils in the Dutch East Indies and the Philippine Islands. His results are given in a paper on weathering and soil formation in *Proceedings of the American Philosophical Society* (Vol. 69, No. 2). Many of the conditions favourable to the development of a podsol occur in the heights of those islands. Analyses of the soil samples showed that podsolisation takes place in much the same way as in the lowlands of middle latitudes, though the bleached layer below the dark humus is much thicker. Nevertheless, the author did not find in any of the areas visited a true podsol containing little else but silica. The investigation, on the whole, supports the principles of soil classification on a climatic basis.

Helium and the Origin of Petroleum.—M. N. Rogers discusses a "radioactive hypothesis of petroleum formation" in the *N. Zealand Jour. Sci. and Tech.* for April, 1930. He suggests that methane, arising from the decomposition of the organic substances in sedimentary rocks, is condensed as a result of the ionisation due to the radioactive constituents in the same rocks. Lind and Bardwell have already shown that the effect of α-rays on methane is to produce the higher saturated hydrocarbons and liquid olefines. Rogers assumes that the extent to which such a process has operated in a sandstone may be indicated by the content of helium in the latter. Experiment indicates that for each cubic foot of helium generated nearly two tons of liquid hydrocarbons could be formed. In the Eldorado oilfield of Kansas 70 million cubic feet of helium per annum have been produced. In the Sedan field of Kansas several million cubic feet of gas with about one per cent of helium escape daily. The Petrolia gas-field originally contained more than 1000 million cubic feet of helium. It is further pointed out that radon is about fifty times more soluble in petroleum than in water, and that this might lead to a localisation of radioactivity which would bring about partial elimination of hydrogen and the production of solid hydrocarbons.

Apatite Deposits of Chibina Tundra.—In one of the Scientific Chemico-technical Publications of Leningrad (in Russian, 1929) A. E. Fersmann, the leading geo-chemist of Russia, gives a concise summary of the work done during the last ten years in exploring the Chibina Tundra for apatite. The area is a massif of rocks belonging to the nepheline-syenite family situated north of the Polar circle in the Kola Peninsula not far from the Murmansk railway. The intrusions are laccoliths or ring-complexes in the Pre-Cambrian gneisses of the Fenno-scandian shield. Apatite-nepheline rock occurs in two bands. The one now being exploited has an apatite-rich upper part (average thickness, 50 metres; P_2O_5, 30 per cent.) and a lower part poorer in apatite (average thickness, 150-180 metres; P_2O_5, 10-15 per cent). Parts of the rock range as high as 85 per cent of apatite, and the estimated reserves of the latter amount to more than 500 million tons. The ore was formed at a late stage in the igneous cycle from a residual magma rich in volatile fluxes. It constitutes the greatest of all the Russian phosphate deposits. Preliminary prospecting by borings and construction of roads is now completed and the yield of ore next year is expected to be 200,000 tons. The by-products—nepheline and titanium ore—will be utilised in the ceramic and chemical industries.

Types of Bridges.—An ingenious and original map appears in *Petermann's Mitteilungen*, Heft 5/6, 1930, showing the distribution throughout the world of various kinds of bridges classified first by the material and secondly by the method of construction. The classifications that are mapped include eight types ranging from the simple hanging bridges of lianas and other plants to modern bridges of metal built in spans. Dr. H. Winkler adds a short article to his map. A certain correspondence with forest growth appears in the distribution of all types of wooden bridges, those made of lianas being confined to the region of equitorial rain forests. The Mediterranean forests, how-

ever, do not seem to help bridge construction, for in their area stone bridges in the main predominate. On the whole, the wood bridge in one form or another is found in more than half the land area of the world.

New England Floods.—During the last century, New England has experienced some ten storms resulting in flooding of unusual severity. One of the worst of these was on November 3 and 4, 1927, and it is the subject of a report by Mr. H. B. Kinnison (U.S. Geological Survey, *Water Supply Paper*, 636-C). Torrential rain fell over much of New England, causing very severe floods, and loss of life and destruction of roads, bridges, and houses in Vermont, New Hampshire, Massachusetts, Connecticut, and Rhode Island. The storm was caused by somewhat exceptional meteorological conditions. A tropical storm appeared on the weather map over Cuba on Oct. 29, and started to move northward three days later, developing unusual severity. By Nov. 3 the storm centre was off the lower end of Chesapeake Bay. It was then expected to continue up the coast with moderately heavy, but not excessive, rains over New England. However, an area of high pressure to the north-east prevented the storm moving in that direction, and at the same time there was another high-pressure area north of New York State. The moving low-pressure area was caught between the two high-pressure areas and was forced upwards. Torrential rain resulted. Over 500 square miles there was a fall of 9 inches, while over another 36,000 square miles more than 5 inches fell. Several power reservoirs in the area were not full at the time and held some of the flood waters, but the ground was saturated by previous heavy rains, and lakes and swamps were almost full, a state of affairs which led to rapid flooding.

Light Rays as null Geodesics.—Einstein's general theory of relativity was based upon several postulates, which subsequent writers have tried to simplify. Thus Whittaker, in vol. 24 (1927) of the *Proceedings of the Cambridge Philosophical Society*, showed that to obtain the equation of light rays as space-time geodesics of zero length, we need only combine the ordinary theory of partial differential equations and of their *characteristics* (which may be roughly described as loci of singularities) with the simple postulate that a light ray is a line of singularities. Levita-Civita, in vol. 11 (1930) of *Rendiconti della R. Accademia Nazionale dei Lincei*, has carried the simplification a stage farther by eliminating all reference to electromagnetism. He shows that the light rays can be obtained as characteristics directly from the *gravitational* equations, independently of any electromagnetic theory of light.

Collisions of α-Particles with Nitrogen.—Prof. W. D. Harkins and Mr. A. E. Schuh have contributed a paper to the *Physical Review* for April 1, in which an account is given of some investigations of the production of oxygen from nitrogen, presumably those to which reference was made recently in NATURE (April 19, p. 611). It appears that 39,000 photographs of 390,000 tracks of α-rays from thorium C and C′ were taken in a Wilson cloud apparatus containing nitrogen. Two 'disintegration-syntheses' were observed, in which it appeared that oxygen (O^{17}) had been formed by the addition of an α-particle to nitrogen (N^{14}), with simultaneous expulsion of a proton. One of the two photographs has been reproduced. The number of collisions per million α-rays of range 8·6 cm. in which reorganisation of the nuclei took place was only one-quarter of the number previously obtained by Mr. Blackett, but the number of elastic collisions in which the α-particle was deflected through more than 90° was 100, compared with Mr. Blackett's 32. With such small numbers, no importance can be attached to apparent differences in yield of this order, but the numbers in question are definitely less than would be expected from the researches of Drs. Kirsch and Pettersson.

Melting-Point of Pure Tellurium.—With the view of a closer study of the strange behaviour of fused tellurium dioxide towards platinum, especially under the influence of a direct electric current, Prof. A. Šimek and Dr. B. Stehlík, at the Masaryk University of Brno, have prepared some elementary tellurium in the purest possible state. These authors then made an accurate determination of the melting-point of this 'metallic' tellurium by an electrical method whereby the temperature of a resistance furnace was raised steadily and uniformly by two, three, or four degrees C. each minute. The temperature was measured by means of thermo-elements of 'Heræus' platinum and a ten per cent. rhodium-platinum alloy. The thermo-electric force of the couple was measured by a calibrated double potentiometer connected to an aperiodic mirror galvanometer giving a deflection of 1 mm. for one microvolt, corresponding to 0·1° C. in the temperature range used. The melting-point *in vacuo* was 452·0° C., but was lowered by about 0·15-0·2° C. in hydrogen and in carbon dioxide at one atmosphere pressure. This the authors explain as being due to the solubility of the gases in fused tellurium.

Chemistry of Menthone.—In an article on recent progress in the menthone chemistry in *Chemical Review*, vol. 7, No. 1, Prof. J. Read explains how much light has been thrown in recent years upon the constitution of products derived from oil of peppermint by researches upon the ketone *piperitone*, which can be obtained in dextro-rotatory, lævo-rotatory, and racemic forms from *Eucalyptus*. The genus *Eucalyptus* which abounds in Australia embraces about 300 species and is of immense scientific and economic importance on account of its timbers, essential oils, exudations, and dyes. By reduction of piperitone in contact with colloidal palladium one molecular proportion of hydrogen is added and a mixture of menthones of reversed and enhanced optical rotatory power is produced. Thus *l*-piperitone, of which $[\alpha]_D = -51·5°$, gave on reduction a mixture of *d*-isomenthone and *l*-menthone with $[\alpha]_D = +65·1°$. By the action of heat or of alkalis, racemisation of piperitone is effected through enolisation which destroys the asymmetry, whereas menthone under similar conditions undergoes an apparent 'inversion'. In this case, however, enolisation affects only one of two asymmetric carbon atoms, so that the product remains optically active, though reversed in sign, and the problem is complicated by the superposition of geometrical upon optical isomerism. Thus the actual product is not the enantiomorph of menthone but its geometrical isomer and the term 'inversion' has been erroneously applied. Study of the menthylamines has furnished interesting data for the development of the principle of optical superposition, the main obstacle to the solution of which problem lies in the great difficulty of gaining access to complete stereo-isomeric series of suitable substances. The last section deals with speculations upon the biogenetic origin of different natural oils from related species. In this difficult field the author finds that striking relationships centre around piperitone. The very delicate control of molecular transformations which may result in producing dextro-rotatory and lævo-rotatory isomers in different plants appears to be still inseparably associated with the vital process.

The Department of Animal Genetics, University of Edinburgh.

THE scheme formulated in 1911 by the Development Commission for the further development of agricultural education and research included the creation of a number of research institutions. To Edinburgh was allotted an Institute of Research in Animal Breeding, and in 1913 a Joint Committee, including representatives of the University and of the College of Agriculture, was called into being. Its activities were completely interrupted by the War, and it was not until 1919 that they were resumed. It was decided, owing to the general uncertainty which prevailed at this time, to make a very unambitious beginning.

The first home of the Department was an old fever hospital in the High School Yards, placed at the disposal of the committee by the University authorities, but by 1924 this accommodation had become entirely inadequate, not only for the experimental animals, but also for the staff and their guests. Emeritus Professor Sir James Walker placed seven rooms in the new Chemistry Department at King's Buildings at the disposal of the Joint Committee, and the University Court granted the use of seven acres of grass land.

In 1927, as a result of a report made by its representative, the International Education Board of America granted a sum of £30,000 toward the building and equipment of the Department, and the endowment of a chair in animal genetics in the University. This offer was conditional on a like amount being raised from other sources, and on the provision of funds adequate for maintenance. Through the generosity of private individuals, notably Lord Woolavington, Lord Forteviot, and others, and of public bodies, including the Development Commission, the Empire Marketing Board, the Highland and Agricultural Society, and the University Court, this sum was raised or guaranteed. Plans of a new building were prepared by Messrs. Lorimer & Matthew, and building operations were commenced in September 1928.

The new building is situated to the west of the Chemistry block and has the form of a T with the cross-bar and the main entrance frontage, 91 feet long, facing due east. It measures 140 feet from east to west, and consists of four floors, including a so-called basement and excellent attic accommodation, these being as well lighted and serving as useful purposes as do the ground and first floors. A feature has been made of the centre of the symmetrically treated front. The entrance doorway is recessed under a wide low arch and is approached by a flight of steps and flanked by shaped parapet walls, the whole being surmounted by a shaped gable after the Dutch style, having carved upon it a symbolical group representing the continuity of life.

FIG. 1.—Department of Animal Genetics, University of Edinburgh.

The building is harled with stone facings and corners and the roof is covered with Ballachulish slates. All the floors are of reinforced concrete and in the corridors they are covered with terrazzo. The lecture theatre with its barrel vault carried up into the roof space is well lighted and is seated for 120. The principal staircase is constructed in synthetic stone and has a simple but very fine wrought iron railing with ornamental panels.

On the ground and first floors are the rooms of the staff and of the guests. In the basement are the

constant temperature and X-ray rooms, animal rooms, staff common room, workshop, store room, lavatories, and also an unloading room in which packages can be transferred from a lorry directly into the electric lift which serves all floors. A caretaker's house of five rooms occupies the west end of the floor. In the attic, which runs the whole length of the building, are the aquarium, aviary, terrarium, and store room.

In the entrance hall are panels framed in oak with the names of students who have taken higher degrees whilst guests of the Department. At the top of the panels there is carved "De fructibus suis agnoscebantur." Under this honours panel there is an oak table and stools.

The heating of the Department is by low pressure steam.

In addition to this main block there lies, to the south-west, a sheep building provided by the Empire Marketing Board and equipped with operating theatre, sterilising and instrument rooms, food stores, and sheep pens. To the north-west there is a large brick intensive poultry house accommodating 200 birds. To the north there are the large pig building and goat house provided by the Department of Agriculture for Scotland. Several wooden buildings house the rabbit, rat, and mouse colonies, whilst others accommodate the monkeys and fowls.

The new building was officially opened on Monday, June 30, by the first chairman of the Joint Committee on Research in Animal Breeding, Sir Edward Sharpey-Schafer, president of the Royal Society of Edinburgh. At the opening ceremony, the degree of Doctor of Laws, *honoris causa*, was conferred by the Vice-Chancellor, Sir Thomas Holland, upon Mr. T. B. Macaulay, the president of the Sun Life Assurance Company of Canada, a Canadian with strong Scottish connexions, who has shown considerable interest in the affairs of the department and has endowed therein a lectureship and several assistantships.

The Museums Association and Museum Extension.

THE forty-first annual conference of the Museums Association, which met at Cardiff, on June 23-27, by invitation of the Lord Mayor and Corporation and of the National Museum of Wales, was successful in all aspects. It was attended by more than 230 delegates and other members from all parts of the British Isles, as well as from the United States, Germany, and Sweden; these represented all classes of museums, from the great national institutions to the smallest village museums. The last statement strikes the main note of the conference: the knitting up of the museum service of the country and its extension to the remoter districts, a subject on which valuable discussions took place. The National Museum of Wales has itself set a brilliant example of such work, and, with its beautiful building and admirable arrangement, formed an inspiring focus of the proceedings. The guidance of its officers, the hospitality of the Lord Mayor, of the Mayors of Newport and Merthyr Tydfil, of Lord Treowen, and of numerous friends combined with the fine weather and the charm of the surrounding country to make the stay of the visitors as delightful as it was profitable.

The president, Sir Henry Miers, referred in his address first to the Report of the Royal Commission on National Museums and discussed the suggestions which it made for the co-operation of the Museums Association. In the event of a Standing Commission being appointed, it was hoped that the Association would have official representation on it. The proposed enlargement of the Circulation Department to include all suitable classes of museum material would be an important factor in co-ordinating museums, while the extension of the method of affiliation adopted by the National Museum of Wales should assist in their co-operation. Plans for a training course, as desired by the Royal Commission, were already published in the *Museums Journal*, and it was hoped that municipal bodies would assist their junior officers to attend. The scheme for a National Open-Air Folk Museum was making good progress in the hands of a strong committee.

Turning to the proposals of the Carnegie Trustees, the president said that the advice of the Association would be asked when grants were allotted to museums; it was necessary that museums should fulfil the conditions laid down in his own published report to the trustees; meanwhile museums might consider plans of work to which they might apply any possible grant. For the Association to perform the duties requested of it by the Royal Commission and by the Carnegie Trustees, it was necessary that it should acquire a legal status; as a first step it was proposed "that the Museums Association be converted into a Company limited by guarantee and not having a share capital." This, with the consequent changes in the constitution of the Association, was accepted by the subsequent general meeting, which fixed the amount of the guarantee at 10s. for each member.

Finally, the president repeated some of his previous recommendations, as that the museums of a district should combine to hold a district loan exhibition; that museums should distribute their surplus material, and render their research material more available for workers; and that they should prepare educational exhibits for circulation to schools and to towns or villages unprovided with a museum.

This last was the subject of two papers by Dr. T. W. Woodhead, of Huddersfield, and Mr. W. C. Sprunt, of Batley, who described the kind of exhibits sent out, the mode of packing, and the system of distribution. It was pointed out in the discussion that museums had been doing this work long before the libraries took it up. There has, however, been no systematic attempt to provide branch museums in the villages for those of more mature years, at least so far as Great Britain is concerned. The numerous rural museums in Sweden, of which Dr. Klein of the Northern Museum gave an entertaining account, are independent folk museums of high value in promoting local patriotism but not educational in the formal sense. The same may be said of the *Heimatmuseen*, now springing up all over Germany, of which the ideals were eloquently expounded by Dr. Otto Lehmann.

The more usual type of small museum was in the minds of Dr. F. J. North and Mr. H. A. Hyde, who showed what it might usefully exhibit in geology and botany respectively. The affiliation of such museums to a central museum was discussed by Dr. Cyril Fox, from his experience as director of the National Museum of Wales. He had found the chief difficulty in any scheme to be the lack of a permanent and competent curator; the parent museum could neither lend nor give material to a museum that was unable to care for it.

The Carnegie Trustees had sent their assistant secretary, Mr. A. B. Hyslop, to glean suggestions that might help towards some scheme of museum extension to rural areas. They were hoping to take counsel with the County Directors of Education and with the Circulation Department of the Victoria and Albert Museum; but it is clear that the burden of the work

must fall on local museum curators, just as that of library extension has been borne by public librarians. There can be no question of the willingness of curators to help; many of them have been doing the work for years, sometimes with the co-operation or at least the sanction of the educational authorities, sometimes in spite of their lethargy, and out of their own slender resources. If the Carnegie Trustees can induce the educational authorities in any one area to co-operate whole-heartedly with the museum curators, an example will speedily be set which the rest of the country will feel bound to follow. It is, however, to be hoped that the benefits will not be confined to school-children, but that the needs and interests of others, especially the adolescent, will be kept prominently in view.

International Congress of Actuaries.

THE ninth international congress of actuaries was held at Stockholm on June 16-20 and was largely attended by actuaries from all over the world. The arrangements were made by the Swedish Society of Actuaries and the Swedish Association of Assurance, and the presidents for the time being of those bodies (Dr. Phragmén and Mr. Sven Palme) being the joint presidents of the Congress. Several subjects were chosen for discussion and the papers submitted were printed in English, French, or German, at the author's choice, with abstracts in the other languages. Each subject was then introduced by a short speech by a Scandinavian actuary and a general discussion followed.

One of the subjects of most general interest discussed at the Congress was the treatment of sickness and disability in social insurance or in connexion with pensions or life assurance, and it was apparent that the granting of these benefits on invalidity has led to far heavier rates of invalidity than those prevailing prior to the institution of the schemes. This effect is noticeable whether we look at State or private schemes of insurance. Attention had already been directed to the point in England, and most other countries are having to face the same difficulties. It is probably inevitable that, even if definite malingering be excluded, some such result should appear, but it makes the actual expense of such schemes greater than the estimated expense on the basis of older experience acquired in different conditions. The subjects of general scientific rather than professional interest were the statistical evidence available with regard to the influence of tuberculosis on mortality and the application of modern statistical treatment to problems of risk. In connexion with the latter, non-Scandinavian actuaries had the opportunity of considering Lundberg's interesting new theory of risk, and it was satisfactory to find a paper giving a definite warning against the assumption of the normal curve, in connexion with the discussion of deviations in assurance work, when Poisson's law would be a proper assumption.

On the strictly actuarial side, the fair distribution of surplus was discussed by many actuaries in written and verbal communications, while on the practical life assurance side the comparison of 'participating' with 'non-participating' assurances and the relative advantages of assurances that merely cover risk, as compared with those that are largely for purposes of saving, evoked a good discussion.

The meetings were held in the new concert hall and the arrangements were excellent. The interpreting was remarkably good; thanks partly to the choice of linguists with a first-class knowledge of the subjects under discussion.

The Congress was graciously received at the Royal Palace for tea by H.M. the King, and the Crown Prince, as Président d'honneur, attended and spoke at the opening meeting. It only remains to record the generous hospitality of our Swedish hosts to the members of the Congress and their wives: it would be hard to imagine greater kindness. W. P. E.

Rayleigh Collection at the Science Museum.

AMONG recent additions to the Science Museum, South Kensington, is a most interesting collection of apparatus used by the late Lord Rayleigh in the course of his scientific research. On the occasion of the unfortunate fire, last year, at Lord Rayleigh's home at Terling, Essex, a considerable quantity of apparatus was destroyed, but the historical apparatus was fortunately undamaged and the bulk of it has been generously given by the present Lord Rayleigh to the Science Museum, where it should prove a continual source of interest and inspiration to professional and amateur scientific workers alike. It is scarcely necessary to remind readers of NATURE of the extent and importance of the late Lord Rayleigh's contributions to science. During a period of more than fifty years he published no fewer than 446 papers, every one of which made a distinct addition to our knowledge of the subject and was characterised by that lucidity and elegance of expression for which its author was renowned.

On viewing this collection, one is struck very forcibly — as were visitors to the laboratory at Terling — by the extraordinary simplicity of the bulk of the apparatus. The ability to attain results of the highest accuracy and importance by the aid of odd bits of wood, glass tubing, wire, and sealing-wax was undoubtedly bound up with Rayleigh's unerring instinct in discriminating between the essential and the non-essential. It is doubtless true that some branches of modern physical research cannot profitably be pursued without the use of expensive apparatus. At the same time, many workers who are apt to grow despondent after a perusal of the price-lists of the scientific instrument makers should find a tonic in the Rayleigh collection, which also serves as a salutary reminder that the man is more important than his tools.

The present collection is thoroughly representative of the vast field which Lord Rayleigh covered, and is exhibited in six cases, two dealing with acoustics, while the remainder come under the headings of optics, magnetism and electricity, argon, and miscellaneous. It is impossible in a short notice to deal adequately with the whole of the exhibits, but a few representative examples may perhaps be mentioned. The acoustics section includes apparatus used in experiments on reflection and interference and on the intensity of aerial vibrations; also the apparatus by means of which it was demonstrated that our lateral perception of the direction of a sound depends upon the phase-difference at the two ears. One of the most important exhibits in the optical section is the apparatus used for the determination of the constant of the magnetic rotation of light in carbon disulphide, while there is also a reminder that, so early as the year 1902, Rayleigh made an attempt to detect motion through the æther. Prominent in the electrical section will be found

apparatus for determining the laws of resistance of periodic currents. The argon collection gives an excellent idea of the course taken in that classical series of investigations extending from 1892 to 1895 in the latter part of which Sir William Ramsay collaborated, while under 'Miscellaneous' the chief exhibits deal with capillarity, fluid motion, and cognate problems. Every piece of apparatus has been provided with a full explanatory label giving references to the original source and to the "Collected Scientific Papers," and public lectures on the exhibits will be given from time to time.

South-Western Naturalists' Union.

THE eighth annual conference of the South-Western Naturalists' Union, attended by individual members and representatives from affiliated societies in the six south-western counties, under the presidency of Dr. F. A. Bather, was held at Gloucester, on June 13–15, at the invitation of the Cotteswold Naturalists' Field Club. Members were welcomed by the Mayor of Gloucester (Councillor S. J. Gillett) and the president of the Cotteswold Field Club (Prof. H. L. Hawkins), and were entertained at a reception in the Museum, where, in addition to the other exhibits, several beautifully executed ancient charters of the city were specially displayed. By the courtesy of the mayor and corporation, meetings were held in the Guildhall, and on the morning of the second day a long business agenda was tackled. A suggestion put forward that the management of the Union's affairs should be entrusted for limited periods to local committees appointed by the affiliated societies in circumscribed areas in rotation was remitted for future consideration.

Dr. Bather in his address, entitled "Evolutionary Enigmas", first sought to make the idea of organic evolution more precise, and, by examples drawn from fossil invertebrates, to present a series of proofs gradually increasing in force. Modern studies in palaeontology and in genetics had, in his opinion, thrown doubt on the older phylogenetic conceptions and on the origin of life-forms from a homogeneous material. He preferred to start with a multitude of diverse units, which by combination produced a great number of organisms differing in qualities and potentialities. These, he thought, had been sifted and assorted by a succession of varied environments, a process which, strictly speaking, was not evolution. Evolution came in when change in the constitution of one or other heritable unit provided new material for sifting. There was reason to believe that such change could be produced by change of outer conditions, though it had not been proved that the change was necessarily in harmony with the conditions. This whole conception was opposed to Herbert Spencer's definition of evolution.

Two excursions were made. On the afternoon of the second day a number of ancient buildings were inspected under the guidance of Mr. Roland Austin, City Librarian; afterwards the party was conducted over the Cathedral by the Archdeacon, the Ven. C. H. Ridsdale. On the concluding day a portion of the Cotswolds was toured by motor cars. A halt was made at 'The Chandlers', Witcombe, where Mrs. E. M. Clifford exhibited and explained in detail numerous Neolithic, Palaeolithic, and Romano-British finds from the Barnwood gravel pits. Many of the objects form the subjects of papers prepared for publication in scientific journals. The special aims on the excursion were a survey of the geological conditions in an area lying between the courses of the Severn and the Thames, particularly with regard to river development, and the inspection of certain exposures, notably a fine one in the Great Oolite at Foss Cross. The physical features of the region were most ably demonstrated and interpreted by Dr. D. E. Finlay, the honorary secretary of the Cotteswold Naturalists' Field Club.

Annual Inspection of the National Physical Laboratory, Teddington.

ON Friday, June 27, the General Board of the

inspection of the laboratory. As is usual on this occasion, a large number of visitors, including representatives of scientific and technical institutions, government departments, and industrial organisations, were present and were received by Sir Ernest Rutherford, chairman of the General Board, Sir Richard Glazebrook, chairman of the Executive Committee, and Sir Joseph Petavel, Director of the Laboratory.

In the duplex wind tunnel in the Aerodynamics Department a large-scale model aerofoil complete with engine nacelle was under test to determine the best position of the nacelle on the leading edge of the aerofoil. To determine the effects of airscrew slipstream on the resistance of the model, it was fitted with its own airscrew operated by an ingenious three-phase motor of small size incorporated in the nacelle. Tests were made with and without the airscrew in operation. The results of the work will be used in the design of a large-size machine of the monoplane type, a complete model of which will then be subjected to further tests to improve it in detail.

A method has been evolved in the department for rendering visible by the use of the dense vapour from titanium tetrachloride the character of fluid motion round bodies used in aerodynamic research. For this purpose a small wind tunnel has been constructed in which models can be placed, the titanium tetrachloride being spread in a thin film along the length of the wing. By suitable means the flow picture can be projected on to a screen, while instantaneous photographs of very short duration can be recorded by focusing a camera on the vapour, which is illuminated by a spark gap and a suitable optical system. By this means photographs showing the departure from laminar to turbulent flow can be obtained.

Of interest also was a method of calibrating the standard pitot tube at low speeds. For this purpose the tube is carried on a small whirling arm and can rotate in a closed circular annulus of mean diameter about eight feet and of one square foot sectional area at controlled speeds, revolutions being recorded electrically. To transmit the pressure difference to the manometric balance the axis of rotation is fitted with a special oil seal. A very sensitive form of manometer embodying the Chattock tilting principle has been designed to measure the small pressures involved. The two cups to which the pressures are communicated are joined by a circuit, which incorporates a length of capillary tube in which an air bubble serves as an indicator, the latter being viewed by a micrometer microscope. The whole instrument can be insulated thermally to avoid temperature effects. With this instrument it is hoped to calibrate the standard pitot tube to a high degree of accuracy at speeds so low as two feet per second.

In the Engineering Department apparatus was

shown for the investigation of the stress distribution in a reinforced concrete column, a matter of interest owing to the complications introduced by the effect of shrinkage on the stress distribution and by the slow yielding of new concrete when stressed. The column was tested in the floor and column testing machine with axial and eccentric loading. The loads are applied through special knife edge end plattens to ensure virtual point loading, any desired load up to fifty tons being obtained by means of a hydraulic ram. The load is measured by means of a system of levers and a jockey weight, and specially designed extensometers are used to determine the small changes in length both in the concrete and also in the steel reinforcing bars.

Other work in progress included an investigation into the effect of surface irregularities and surface conditions in general on the fatigue strength of spring steels. In this investigation specimens are subjected to stresses in rotating cantilever machines running at about 2000 revolutions per minute, in high-speed repeated bending machines or in a torsional fatigue machine. It has been found that surface irregularities, surface decarburisation during manufacture or heat treatment and surface cracks formed during heat treatment have the effect of lowering materially the fatigue strength of specimens, and that their resistance to fatigue can be increased by removal of the surface layer. The research has been conducted in conjunction with the Metallurgy Department, and for the study of the effect of decarburisation a specially designed vacuum furnace has been constructed in which specimens can be hardened and tempered by quenching without contact with the air. Specimens of a spring steel treated in this manner have shown fatigue resistance closely approaching that of corresponding ground and polished specimens.

Among the researches in progress in the Metallurgy Department mention may be made of an investigation into the effects of different forms of heat treatment on the permanence of dimensions of heat-treated aluminium alloys. As a consequence of such treatment, internal stresses may be set up leading to distortion in specimens during machining. Slowly cooled alloys are free from such stresses, and those which are quenched with moderate rapidity are less liable to them than those which are subjected to rapid quenching, and attention is being given to the quenching operation. Specimens quenched in cold water, cold oil, or boiling water have been machined and afterwards examined for distortion by the Metrology Department. The exhibit illustrated the effect of such treatment and of the composition of the alloys on their behaviour.

Work was also in progress in connexion with steels for use at high temperatures, and one object of the work is to ascertain their resistance to scaling when exposed to flame gases. In the investigation in progress, steel wire in the form of a spiral coil is exposed to contact with typical flue gases at various high temperatures, and the effect on it is determined by measurement of the changes in its weight and electrical conductivity. Suitable arrangements are made for the control of the temperature and composition of the gas.

Of interest also was an exhibit showing the effect of the presence of high phosphorus and silicon in wrought iron on the γ-α transformation. This transformation is suppressed and grain refinement prevented if these impurities are present in excessive amounts. This phenomenon has been found to have an important bearing on the strength of wrought-iron chains and hooks in which a coarse structure impairs impact strength.

In the Metrology Department a new primary standard barometer was on view. The design of this instrument is such that the height of the barometric column can be compared directly with a line standard. The barometer, which is of stainless steel and provided with optically flat and parallel windows, and the line standard are mounted on a heavy base, and a pair of micrometer microscopes mounted one above the other on a vertical column can be focused alternately on the mercury column and the line standard. A mercury vapour pump is used to produce the vacuum above the mercury column, any residual pressure being measured by means of a M'Leod gauge. Means are provided for determining the temperature of the mercury column.

Of interest also were two pieces of apparatus for the testing of surface plates. In the first the surface plate to be tested is compared with one whose errors in flatness have been determined. It consists of a metal plate fitted with three adjustable ball feet and equipped with an indicator the ball foot of which is in line with and midway between two of those of the plate. By placing the apparatus first on the known and then on the unknown surface and noting the corresponding indicator readings, it is a simple matter to determine the errors in the plate under test. In the second piece of apparatus the test plate is submerged under mercury and the depth of its surface below that of the mercury is measured at various points by means of the apparatus, which takes the form of a tripod with a central vertical micrometer screw. The legs of the tripod are of ebonite fitted at the bottom with hardened steel balls, and the contact of the micrometer screw with the mercury is indicated electrically. The apparatus has been found to be accurate to 0·0001 in.

In connexion with research work for the Food Investigation Board, a distant reading hygrometer has been developed in the Physics Department for humidity measurements in the holds of ships carrying frozen lamb. The instrument is essentially a wet and dry bulb thermometer in which the conventional thermometers are replaced by thermojunctions arranged differentially. The potential difference between the thermojunctions can be measured on a millivoltmeter the readings of which can be converted to temperature differences by previous calibration. Provision is made for wetting one set of thermojunctions.

Of interest also was a sensitive method of detecting the dew point by the employment of a photo-electric cell mounted below a polished steel plate which serves to collect the dew. The plate is illuminated by a small lamp in such a manner that in the absence of dew the reflected light does not affect the cell. Formation of dew results in light scattering and consequent illumination of the cell. The latter is incorporated in a valve circuit including a telephone earpiece, and the design of the circuit is such that the presence of dew is indicated by cessation of sound in the telephone. The temperature of the steel plate is determined by thermocouples fixed to its upper surface.

For the measurement of noise a portable instrument has been designed in the Sound Division. In this instrument a buzzer supplies alternating current to a telephone, the strength of the current being controlled by a potentiometer. The current is adjusted until the sound in the telephone is judged to be equal in intensity to the noise, or alternatively is just masked by the noise. The sound intensity can be varied in fourteen steps from extreme loudness to an intensity below that of ordinary speech.

In the Radiology Division, an X-ray investigation on the effects of heat treatment on tungsten magnet

steels was in progress. Arrangements have been made for the study of such effects up to a temperature of about 1200° C. The specimen is provided with its own heating coil in the X-ray spectrometer, and provision is made for the adequate cooling of the photographic film by means of a suitable water jacket. The investigation has shown that under appropriate conditions of heat treatment crystals of at least two carbides are present, their amount depending on the quenching temperature.

In the Optics Division various apparatus for the evaluation of total energy flux was shown. The exhibit included horizontal and vertical test benches for the comparison of lamps used as standards of radiation, or of radiometric instruments such as thermopiles, bolometers, radio-balances, etc. The instruments shown comprised various thermopiles, both air-exposed and vacuum types, sunshine receivers both of the bolometric and thermoelectric pattern, gas fire bolometers, and two Callendar radio-balances for absolute measurement of radiation intensities. Special electrical measuring circuits for use in testing these various instruments were also shown. These included a portable equipment for use out of doors with either bolometric or thermoelectric instruments for solar work.

For precision testing of voltage transformers, a new shielded resistor for 30 kilovolts has been designed and constructed in the Electrotechnics Division. In this piece of apparatus the importance of keeping phase errors to a minimum has been the main consideration. The resistor is divided into six sections rated at 5000 volts each, every individual section being composed of forty elements, each of 2500 ohms resistance. To eliminate capacity errors so far as possible, each section is enclosed in a metal container which is maintained at the mean sectional voltage by connexion to a suitable point of a similar unshielded resistor in parallel.

Of interest also was a method of determining the electrical resistance of small irregular samples of metals and alloys. A measured current is led into the specimen through two very small steel balls 9 mm. apart, and the voltage between two selected points is measured by means of a low reading potentiometer, the voltage leads making contact with the specimen through two needles 3 mm. apart. The resistivity is determined by making similar measurements on a piece of metal of known resistivity and of similar shape.

In the High Voltage Building demonstrations were given of flash-over tests on transmission line insulating systems under dry conditions and when sprayed with artificial rain. For the latter tests rain water is collected in a special tank, tap water being unsuitable owing to its conductivity being approximately three times that of pure rain water.

In the Electric Standards Division a method of determining the properties at audio frequencies of alternating current milliammeters incorporating copper oxide rectifiers was demonstrated. Such milliammeters are known to possess frequency errors, and these have been found to be of an unusual type and to be due to the capacity of the rectifiers. It has been found possible to compensate for these errors by providing the instrument with a suitably designed inductive shunt.

In the Wireless Division an automatic method of recording bearings from a rotating beacon transmitter was demonstrated. The transmitter, which is situated at Orfordness, consists of a frame coil rotating uniformly once per minute, the rotation being controlled by a tuning fork and phonic motor. The output from the receiver is supplied to a selective tuned audio-frequency amplifier followed by a rectifier, in the anode circuit of which a relay is included. A magnetically operated pen traces a record on a rotating drum the speed of which is maintained at the rate of one revolution per minute by the same means as in the case of the transmitter. A special signal is sent out when the normal to the coil of the rotating beacon lies in the north and south meridian, and the pen is automatically lifted when the two minima occur. Then since the signal strength is proportional to the cosine of the angle between the plane of the transmitting coil and the direction from it of the receiver, the mid-point of the two minima gives the bearing with respect to the north, which can be read off with a protractor or by degree lines printed on the drum.

In the Photometry Division a new type of high precision spectrophotometer has been developed in which there are no moving optical media. Two tungsten gas-filled lamps are used as light sources, and the photometric scale of the instrument is determined in terms of sector discs of known transmission and the voltage-intensity relation of one of the lamps at a standard wave-length. The voltage intensity relation for other wave-lengths can be computed from that at the standard wave-length. The Maxwellian field of view is utilised to obtain adequate illumination in those parts of the spectrum where visibility is low.

Attention has been given to the measurement of the reflection factor of diffusing surfaces under completely diffused illumination, and a small integrating reflectometer has been designed and constructed for this purpose. The instrument consists of a small internally whitened sphere with two small apertures to admit a beam of light and to allow of observation of the brightness of the sphere wall respectively. A third and larger aperture may be covered by a specimen or by a standard plate coated with the same material as the sphere walls, or left open. Relative brightness measurements of the interior under these three conditions as determined with a Lummer-Brodhun contrast photometer, suffice to determine the reflection factor of the specimen. The advantage of the instrument lies in the fact that direct observation or illumination of the specimen is avoided.

Another interesting exhibit was apparatus for the automatic control of picture gallery illumination. The method involves the use of a photoelectric cell; the current variations in the latter are amplified by means of a valve in the plate circuit of which is included an adjustable relay controlling the gallery lighting. To prevent hunting of the relay due to passing clouds, suitable means are incorporated for introducing a time lag before the relay puts in operation the gallery lights, at the same time avoiding any lag in extinguishing them.

In the William Froude Tank a model of a single screw cargo boat was shown under test in waves. The model was fitted with its own propeller and inboard motor for self-propulsion and equipped with apparatus for recording the speed of the model, the propeller revolutions, and the propeller thrust and torque. The latter were measured by the deflection and torsion respectively of suitably calibrated springs coupled to the propeller shaft and operating recording pens through lever systems. Of interest also was a telescopic pitot-tube for making velocity measurements in connexion with an investigation on ship's wake resistance. The tube is capable of swivelling and is provided with its own ship side valve. With this instrument the velocity of the ship relative to the wake can be measured at various distances from the ship's side and the velocity distribution in the wake thereby determined.

The British Polar Exhibition.

DURING the past few years there has been a remarkable revival of expeditions to the polar regions, and it is to this revived interest in polar lands and seas that the idea of holding a British Polar Exhibition in London is largely due. In opening this exhibition at the Central Hall, Westminster, on July 2, Col. Sir Charles Close, president of the Royal Geographical Society, pointed out that Great Britain had been intimately associated with exploration in the Arctic regions for the past 400 years and in the Antarctic regions for 150 years. It was therefore an opportune moment to recall the great deeds of the past and to direct attention to the possibilities of the future by bringing together a collection of relics, pictures, maps, and documents; to demonstrate more particularly modern means of scientific exploration, especially through aerial methods, and to assist, if possible, the Scott Polar Research Institute at Cambridge with funds for further research work.

Commander L. C. Bernacchi, the organising director of the exhibition, and Capt. L. W. G. Malcolm, assistant director, have been extraordinarily successful in collecting some hundreds of exhibits, every one of which has some personal interest attached to it, and they have arranged the exhibits particularly well so that the ordinary visitor may examine each object without difficulty. The personal kit and notebooks of individual explorers occupy the widest space, and among the numerous interesting exhibits may be mentioned Shackleton's boat in which he made his famous journey of 750 miles from Elephant Island to South Georgia, thus saving the lives of twenty-two members of the crew of the *Endurance*; the sledge used by Shackleton in 1908 when he got within a hundred miles of the South Pole; a large Antarctic camp scene showing the ship *Discovery* in the background; a large group arranged by the Hudson's Bay Company to illustrate Arctic Canada. One room is mainly devoted to the relics of Franklin and Scott; these relics include Sir John Franklin's signature, his sextant and medicine chest; the autograph journal of Capt. Scott showing the last entries he made in it; Scott's camera, satchel, Bible, and many others. Exhibits such as these naturally appeal to human feeling, and are undoubtedly of great value in stimulating interest in exploration.

The various models of Arctic scenes, together with the Arctic products, will enable the visitor to realise to some extent what the polar regions are actually like. The economic importance of the northern seas can be studied from the large map of the north polar region, showing the fishing grounds from which in 1929 Great Britain obtained 280 million pounds weight of cod, 110 million pounds of haddock, and large quantities of other kinds of fish. These statistics are shown on a large chart. For the scientific student, instruments such as thermometers, compasses, and chronometers used on polar expeditions may be examined. A programme of lectures on polar subjects has been arranged by the exhibition committee, and among the lecturers are Commander Bernacchi and Mr. Stefansson. On certain days some of Ponting's films of the Scott expedition are being shown. The educational advantages of the exhibition are still further augmented by the "Polar Book" which has been compiled specially for this purpose; in concise book form, the various aspects of polar work have been brought together in a series of articles written by well-known experts in Arctic knowledge, and two of Bartholomew's maps showing the polar regions are bound up with the book.

In passing through the various parts of the exhibition, one cannot but be impressed by the enterprise, courage, endurance, and achievements of the men who faced the dangers and hardships of polar exploration; also of the changed conditions under which explorers now set out and of the difference in outlook of men taking part in expeditions at the present time. The economic aim of a Frobisher searching for gold in his Meta Incognita, the scientific expedition of Sir James Ross studying magnetic conditions in the Antarctic regions, the spirit of adventure which urged Shackleton to explore polar lands and seas, are still powerful motives. With the more extensive knowledge of the Arctic regions, due to the work of these early explorers, two new ideas have been gradually coming into prominence since the beginning of the present century. First a political factor has begun to present itself with regard to the ownership of polar lands, and secondly a search for suitable stations for air transport. In fact, some recent expeditions have had as their main or partial object the claiming of new territory and the examination of areas for the establishment of landing-places for aeroplanes. Not only then does the Polar Exhibition remind us of the wonderful deeds of men in past times, but it also provides accurate knowledge of the vast regions around the poles at the present day, and suggests some of the problems that still await solution.

University and Educational Intelligence.

CAMBRIDGE.—The vice-chancellor has given notice that a meeting of the electors to the Woodwardian professorship of geology will be held on Friday, Aug. 1. The stipend of the professor is £1200 a year, or, if he holds a fellowship with dividend, £1000 a year. The professor, as head of the Department of Geology, is paid £200 a year in addition to his stipend as professor, or, if he holds a fellowship with dividend, not more than £100. Candidates are requested to communicate with the vice-chancellor on or before Tuesday, July 22.

The Faculty Board of Economics and Politics has received from Mr. Montague Burton an offer to endow a professorship in the University to be called the Montague Burton Professorship of Industrial Relations. The Faculty Board proposes that the duties of the professor should be defined as "to study and give instruction upon the conditions of employment and the relations between employers and employed, with special reference to the causes of industrial disputes and the methods of promoting industrial peace".

The Harkness Scholarship for 1930 has been awarded to Miss K. M. N. Paterson, of Newnham College, and the Wiltshire Prize to R. N. Quirk, of King's College.

The governing body of Corpus Christi College has awarded to Dr. R. Hilton, assistant physician, St. Bartholomew's Hospital, the Copeman Medal for research in medical and biological sciences. This medal was presented by Dr. S. Monckton Copeman, formerly a scholar of the College. The present award is the first which has been made.

DUBLIN.—The honorary degree of Sc.D. was conferred upon Sir James Jeans on July 4, and the honorary degree of Litt.D. upon Mr. C. Leonard Woolley.

DURHAM.—Honorary degrees were conferred on June 26 as follows: *D.C.L.*—Lieut.-Gen. H. B. Fawcus, director-general Army Medical Services, and Baron Alexander Meyendorff, London School of Economics. *D.Sc.*—Dr. F. G. Donnan, professor of inorganic and physical chemistry at University College, London; Mr. Wilfrod Hall (of Newcastle), and Dr. R. E. Slade. *D.Litt.*—Dr. N. Kemp Smith, professor of logic and metaphysics in the University of Edinburgh.

LONDON.—At the meeting of the University Court on July 2, the offer of Prof. S. Smiles and Prof. A. J. Allmand to found a medal to commemorate the services rendered to King's College and to chemical education by Prof. John Millar Thomson was accepted with thanks by the University. Prof. Thomson first became a member of the staff of the department of chemistry at King's College in 1871 and retired in 1914, after having served for twenty-seven years as Daniell professor and head of the department of chemistry. The medal will be known as the John Millar Thomson Medal for chemistry, and will be awarded annually to the student of King's College who most distinguishes himself in the final year of the special honours course in the department of chemistry.

A University postgraduate travelling studentship of the value of £275 for one year has been awarded to J. E. Keyston. Mr. Keyston obtained the B.Sc. (special) degree with first-class honours in physics as an external student from University College, Nottingham, in 1929, and was awarded the Heymann research scholarship. He proposes to carry on research in physics in Germany.

ST. ANDREWS.—The Senatus Academicus has resolved to confer the honorary degree of LL.D., in October, on Prof. J. A. C. Kynoch, emeritus professor of midwifery in the University. Prof. Kynoch was appointed to the midwifery chair in 1898 and retired in 1928. He was for many years dean of the faculty of medicine.

REVISED regulations for the award of Whitworth scholarships in engineering have been issued by the Board of Education (London: H. M. Stationery Office, 3*d*.). The awards for 1931 are two Whitworth Senior Scholarships (£250 a year for two years), six Whitworth Scholarships (£150 a year), and up to 25 prizes (£10) for unsuccessful competitors for Whitworth Scholarships. All the candidates must have been engaged in handcraft in a mechanical engineering workshop for periods amounting to 30 calendar months and must have spent a certain portion of this time at fitting or erecting. Work at the lathe may be counted but is no longer required. The age limit for the Senior Scholarships is twenty-six. Of the Whitworth Scholarships, five are tenable for three years and are open only to part-time students; for them the age limit is twenty-six instead of as hitherto twenty-two. One of these scholarships (ultimately three) is tenable for one year only and is open to students less than twenty-four years of age who may be attending full-time courses.

THE PRINCE OF WALES attended a dinner on July 7 and spoke in support of an appeal which has recently been issued by the National Union of Students for £30,000 for the purchase and endowment of the headquarters in London of the Union and for a hospitality fund. The Prince described the activities of the Union, referring particularly to the hospitality and travel departments. The former makes arrangements for Dominion and foreign students visiting England, either as study-groups or individuals, and £5000 is urgently required for secretarial expenses. The latter acts for British students proceeding abroad, arranging for their reception by the national unions of students of the countries visited. Another important activity of the Union is the arrangement of student exchanges. The present appeal is for sufficient money to purchase the London office at 3 Endsleigh Street, W.C.1, and to provide for its maintenance. The growth of the Union during the seven years of its existence is proof of the need it fulfils, and there is little doubt that, with the powerful aid given by the Prince of Wales' support, funds will quickly be forthcoming to consolidate and extend its work.

Historic Natural Events.

July 13, 1788. Hailstorms. Hailstorms of unexampled severity and destructiveness raged along two parallel stretches from the Pyrenees to the Baltic; in France 1039 communes were devastated and damage caused to the extent of 24,690,000 francs.

July 13, 1910. Highest Temperature in United States.—Death Valley, a depression below sea level in south-eastern California, is noted for its high summer temperatures, and the shade reading of 134° F. on July 13, 1910, is the highest on record in America. From July 8 to 14 inclusive the thermometer exceeded 127° F. every day.

July 13, 1927. Meteorite near Tilden, Illinois.—About 1 P.M. a brilliant meteor fell with detonations like loud thunder. At a distance of more than one hundred miles it was described as " a piece falling off the sun ". At a height of 15 or 20 miles it burst, showing green and then purple, and after a second bursting became invisible. One stone, weighing nine pounds, fell in the village of Tilden, and was glimpsed for an instant as " a dark streak, like smoke ". It was recovered at once, and to the surprise of the finders was not hot but " noticeably cold ". The largest piece weighed 110 pounds, and another 46 pounds.

July 14–15, 1911. Typhoon Rainfall in Luzon.—During a typhoon which crossed the northern part of Luzon, Philippine Islands, the rainfall in 24 hours, commencing at noon on July 14, amounted to 45·99 in. This is probably the greatest known fall of rain in twenty-four consecutive hours. In the four days, July 14–17, the total fall was 88·14 in.

July 15, 718. Thunderstorm and Hail. About this date the Saracen fleet, after raising the siege of Constantinople, was struck by a severe hailstorm mixed with fire, so that only twenty (according to another authority five) ships could save themselves.

July 15, 971. St. Swithin's Storm. Swithin, Bishop of Winchester, died in 862 and was buried in the churchyard of Winchester, having asked, says William of Malmesbury, to be laid where passers-by might tread on his grave, and where the rain of the eaves might fall on it. A century later he was canonised, and a splendid tomb was constructed within the cathedral for the reception of his remains, but it is related that on the day appointed for their removal, July 15, 971, he manifested his displeasure at the disturbance by sending a great storm of rain, followed by forty wet days. No contemporary writers mention this storm, however, and probably it is a later invention to account for the well-known proverb which, referring to July 15, became associated with his name.

July 15, 1558. Thunderstorm and Whirlwinds in France.—About this date part of France was visited by severe thunderstorms and whirlwinds. A great cloudburst occurred in Thuringia and a powerful whirlwind at Nottingham, which unroofed numerous houses and churches, lifted a child in the air, and raised a great waterspout on the Trent; hailstones said to be 15 inches long fell.

July 15, 1808. Hailstorm at Gloucester.—During the night, after several days of oppressive heat, a violent thunderstorm passed over Gloucester from south to north, accompanied by a hailstorm which did a great deal of damage. The hailstones were very irregular, broad, flat and ragged, and many measured from 3 to 9 inches in circumference. They appeared like fragments of a vast plate of ice, broken into small masses in its descent to the earth.

July 15, 1888. Eruption of Bandai-san (Japan).—After remaining practically dormant for more than a thousand years, the volcano Bandai-san in central

Japan suddenly burst into brief activity. A few earthquakes were felt and then a great explosion occurred that rent the north-eastern wall of the crater. It is estimated that the total volume blown away was three-tenths of a cubic mile; it descended the mountain-side with a velocity of 48 miles an hour and devastated an area of 27 square miles at its foot. The total land-area covered by the falls of dust was 790 square miles. The explosions were accompanied by wind-blasts that tore up trees by their roots and levelled houses with the ground. The number of lives lost was 461, mostly from the fall of rocks and debris.

July 16, 1494. Hurricane off Santa Cruz.—According to Southey's "Chronological History of the West Indies", during his second voyage Columbus anchored off Cape Santa Cruz, and while there "upon the 16th July a violent hurricane occasioned the Admiral to declare that nothing but the service of God and the extension of the monarchy should induce him to expose himself to such dangers".

July 16, 1565. Thunderstorm at Chelmsford.—In Stow's "Annals" it is recorded that on this date "about nine of the clocke at night, began a tempest of lightning and thunder, with showers of hail, which continued till three of the clocke the next morning, so terrible that at Chelmsford in Essex 500 acres of corn were destroyed: the glass windowes on the east side of the Church were beaten downe with also the tiles of their houses: besides diverse barnes, chimnies and the battlements of the church which were overthrowne."

July 17, 1921. Low Thames.—During the great drought of 1921 the flow of the River Thames at Teddington fell on July 17 to little more than a quarter of the normal flow in July. (See Feb. 7, 1921.)

July 17, 1925. Thunderstorms at Hong Kong.—Very severe thunderstorms, accompanied by heavy rainfall, passed over Hong Kong during several days in the middle of July. The most intense storm occurred on the morning of July 17, when a fall of 10·24 in. occurred in 11 hours. The water poured down from the high ground of Victoria Peak in great streams; floods and landslides were general and much damage was caused, especially in the Chinese quarter. In one part of the Chinese district a high retaining wall collapsed, demolishing a row of five houses, and most of the inmates, numbering 150, were killed.

July 18, 1794. St. Petersburg Haloes.—A remarkable display of haloes occurred during the morning. There were visible the haloes of 22° and 46°, the tangent arcs on both haloes, circumzenithal arc, five mock suns, and a number of other unusual features. This display has long been a standard of reference in works on atmospheric optics.

July 18, 1820. Mirage on Greenland Coast. The coast of Greenland in 71° 20′ N., 17° 30′ W., as observed by Scoresby through a telescope from a distance of 35 miles, presented a curious appearance. The hills were drawn out vertically and distorted into the semblance of pagodas and other fantastic erections.

July 19-22, 1515. Floods in Central Europe.—On July 19 six weeks of rain began over the whole of central Europe, causing very extensive floods, especially on July 22. On July 24 there was a violent thunderstorm followed by great floods in Duisburg, and on Aug. 3 a cloudburst in Prussia.

July 19, 1926. Heavy Rain in Hong Kong.—During the filling up of a typhoon which crossed the coast about 100 miles to the eastward, a heavy thunderstorm broke over Hong Kong, and continued for nine hours, during which time the rainfall amounted to 20·43 in., 3·96 in. of which fell between 3 and 4 A.M. The city was flooded and great damage was done.

Societies and Academies.

LONDON.

Royal Society, June 26.—**A. V. Hill** and **P. S. Kupalov**: The vapour pressure of muscle. There is a considerable increase of osmotic pressure in muscle as the result of stimulation. This was measured by observing the change of vapour pressure. The osmotic pressure of resting muscle is exactly accounted for by assuming all the known soluble constituents of muscle to be dissolved in its observed 'free' water. The osmotic pressure of fatigued muscle is in excess of that calculated on the same assumption: presumably some substance, hitherto unrecognised, is liberated as the result of activity. **A. V. Hill**: The state of water in muscle and blood, and the osmotic behaviour of muscle. The 'free' water fraction (defined as the weight of water in 1 gm. of fluid or tissue which can dissolve substances added to it with a normal depression of vapour pressure) has been determined in blood, in protein solutions, and in muscle (resting and in rigor). The amount of 'bound' water in these is very small. The osmotic behaviour of muscles immersed in hypo- or hypertonic solutions is considered.—**W. Sucksmith**: The gyromagnetic effect for paramagnetic substances. A method of measuring the gyromagnetic ratio for paramagnetic substances is described. Hitherto, measurements have been made only on various ferro-magnetic materials, all of which show that the source of magnetic moment is entirely due to the spin of the electron. For a paramagnetic substance, the angular moment produced by a change in magnetic moment is very small, and it has been necessary to utilise low-frequency resonance for building up the resulting impulse to a measurable magnitude. Errors of measurement are discussed in detail, and shown to be eliminated.—**J. C. McLennan** and **R. Turnbull**: The absorption of light by gaseous, liquid, and solid xenon. The inert gases are probably monatomic in the solid and liquid states, as well as in the gaseous. Hence a study of the resonance lines in absorption for the gas at various pressures, and in the solid and liquid states, should reveal important features relating the atoms of the gas to the atoms in the liquid and solid state. The absorption band corresponding to the line λ 1469 A. of xenon is the only one belonging to the inert gases that can be readily investigated; niton is too rare, and all the other resonance lines lie beyond the limit of transparency of any substance which is required to contain the gas or liquid. Liquid xenon is clear and colourless; solid xenon is transparent and like glass. The limit of absorption on its long wave-length side was determined for liquid and solid and found to be between λ 1770 A. and λ 1850 A. The asymmetrical type of absorption obtained with xenon, corresponding to λ 1469 A., is similar to that obtained with mercury vapour, corresponding to λ 2536·72 A., and both these wave-lengths are given by a frequency-formula $h\nu = {}^1S_0 - {}^3P_1$. **L. E. S. Eastham**: The embryology of *Pieris rapæ*—organogeny. The development of the main systems of organs, with the exception of the germ cells, from gastrulation stage to that of completely developed caterpillar is described.—**K. Clusius** and **C. N. Hinshelwood**: Homogeneous catalysis of gaseous reactions. I and II. The decomposition of isopropyl ether, $C_3H_7OC_3H_7 = C_3H_8 + CH_3.CO.CH_3$, is catalysed not only by iodine, but also by various alkyl iodides, and to a smaller extent by alkyl bromides. Chlorides have little influence. Hydrogen bromide is also good catalyst. During decomposition of the ether the alkyl iodides are themselves decomposed even when stable in absence of the ether. The decomposition reaction, whereby a hydrogen atom is

transferred under influence of catalyst from one part of the ether molecule to another, with accompanying rupture of molecule, is a general one. Every collision between ether and iodine in which kinetic energy of approach exceeds 34,300 calories probably leads to decomposition. Heats of activation of this and similar reactions are lower than those of corresponding uncatalysed reactions, and mechanism of activation simpler. Catalyst seems to attack molecule at one specific point. —**C. N. Hinshelwood, K. Clusius, and G. Hadman**: Homogeneous catalysis of gaseous reactions.—III. The assumption that energy of activation is supplied by collisions between aldehyde and iodine molecules leads to a calculated rate of reaction ten times smaller than the observed. The assumption that energy is also derived from one internal degree of freedom brings calculated and observed rates into agreement.—**R. H. Fowler**: A possible explanation of the selective photo-electric effect. A theory of the selective photo-electric effect is proposed, which refers the effect to a selective transmission coefficient of the surface layer for incident electrons of a certain energy. Such a selectivity is found theoretically when the potential energy curve near the surface contains two hills separated by a fairly deep valley. Experimentally, retentive emission is only found for surfaces covered with a rather complicated surface layer with first electro-negative and then electro-positive material deposited over the original metal. The proposed theory seems to be in full accord both with the nature of the effect and the peculiar conditions of its occurrence.—**Lord Rayleigh**: The ultra-violet transmission band of metallic silver as affected by temperature. The ultra-violet transmission band of metallic silver at λ 3200 is examined at various temperatures. Heating shifts it towards the red. The shift from 180° C. to 254° C. is 120 Angstroms. **L. H. Gray**: The scattering of hard γ-rays. Tarrant has shown that the absorption coefficient of hard thorium-C″ γ-rays in certain elements is considerably greater than the value predicted by the Klein-Nishina formulæ, while in other elements the measured absorption coefficient is in good agreement with theory. To test whether the extra energy absorbed by the abnormal elements was re-emitted as quantum energy, the secondary radiation emitted between 16° and 90° by aluminium (abnormal) was compared with that from sulphur (normal) using as a primary beam radium-C γ-rays filtered through 4 cm. of lead (mean quantum energy about $1 \cdot 7 \times 10^6$ e-volts). Taking into consideration probable experimental error, it is unlikely that secondary radiation from aluminium exceeds that from sulphur by more than 0·25 per cent. Having regard also to the fact that the same γ-ray beam produces equal ionisation per unit volume in chambers of which the walls are composed of carbon, aluminium, and sulphur, it appears that the new absorbing mechanism is almost entirely inoperative in aluminium, in the case of quanta of energy $1 \cdot 5 \times 10^6$ e-volts, and only becomes of considerable magnitude as quantum energy approaches close to that of the hard thorium line ($2 \cdot 65 \times 10^6$ e-volts). **G. Temple**: The operational wave equation and the Zeeman effect. This paper gives a treatment of the Zeeman effect based on the operational wave equation discussed in two previous papers. —**H. Dingle**: The spectrum of ionised fluorine (F II). The spectrum of ionised fluorine from the infra-red to the Schumann region has been obtained by passing discharges of appropriate intensity through silicon tetrafluoride, and 469 lines have been obtained and measured. The spectrum has been analysed and 173 lines have been classified as term combinations. The analysis has been discussed in relation to theoretical expectations.

ADELAIDE.

Royal Society of South Australia, April 10.—**Chas. Fenner**: The major structural and physiographic features of South Australia. One of a series of papers dealing with the general geography of South Australia. Maps and diagrams were presented to illustrate the various earth movements whereby the coastlines, mountains, valleys, and plains of South Australia have been formed, with plans and sections to show the way in which the work of wind and running water have modified the landscape as we now know it. A modified theory of the origin of the Mount Lofty Ranges was put forward in the endeavour to account for the complex features of that region.—**H. K. Fry**: Physiological and psychological observations on the Australian aborigines. Tests of visual spatial perception showed that the natives reacted to standard illusions similarly to Europeans, but that visualisation of perspective depended on school training. Numerical sense of natives was excellent in guessing differences in contrasted groups of numbers, but ability to arrange a sequence of numbers was a result of arithmetic education. Various problems were solved more or less effectively. Visual acuity of native children was abnormally keen. Tactile and pain sensation, contrary to expectation, were found to be almost the same as that of whites.

COPENHAGEN.

Royal Danish Academy of Science and Letters, Jan. 17.—**Johs. Lindhard** and **Jens P. Muller**: On the origin of the initial heat in muscular contraction. The usually accepted explanation of the initial heat curve of an isometric muscle cannot be maintained; the deformation of the muscular fibre during contraction may be responsible for the surplus of heat in the first phase of heat production.

Feb. 14.—**O. B. Boggild**: The structure of mollusc shells. Previous examinations of the structure of calcareous shells were of a rather sporadic kind, and a more systematic investigation has been undertaken. The examination essentially includes the distribution of the two substances, calcite and aragonite, and the manner in which they are arranged in the shells.

April 11.—**Harald Bohr**: The variation of the argument of an almost periodic function.

May 9.—**Martin Knudsen**: Radiometer pressure and coefficient of accommodation. Radiometer forces have been investigated under such conditions that all the quantities on which the radiometer force may be conceived to depend have been measured, more especially the differences of temperature. The importance of the coefficient of accommodation for the radiometer pressure is shown, and from measurements at low pressures it is found that, in the case under investigation, the coefficient of accommodation for the internal energy (rotational energy) of a diatomic gas may be put equal to the coefficient of accommodation for the translation energy.

SYDNEY.

Linnean Society of New South Wales, April 30.—**Ida A. Brown**: The geology of the south coast of New South Wales. Pt. 2. Devonian and older Palæozoic rocks. There is a progressive increase in the intensity of the folding from north-east Gippsland, Victoria, through the Eden district northwards to Yalwal, near the Lower Shoalhaven River, while the arcuate arrangement of the trend-lines suggests compression against the massif of older rocks lying to the east. Rocks of proved Silurian age are only known to occur in the Bendithera-Wyanbene belt, west of the Deua River. Ordovician graptolite-bearing slates outcrop near Cobargo; the age of the

slates, cherts, and schistose rocks outcropping over the greater portion of the south coast area is not definitely known.—**A. L. Tonnoir**: Notes on the genus *Apistomyia* (Diptera) and description of a new species. A key is given to the species of *Apistomyia*, one of which, from Mt. Malabar, Java, is described as new. —**H. J. Carter**: Australian Coleoptera: notes and new species (7). Nineteen species are described as new. The Buprestidæ described testify to the continuous value of close co-operation with the British Museum. The remaining descriptions are chiefly the result of correspondence with various Australian collectors. —**W. L. Waterhouse**: Australian rust studies. (2) Biometrical studies of the morphology of spore forms. Spore measurements of æcidiospores, uredospores, and teleutospores of physiological forms of varieties of *Puccinia graminis*, and of uredospores of *P. triticina*, revealed striking morphological likenesses and differences between certain of the forms, but parallelism between physiology and morphology does not necessarily exist.

Research Workers in Industry.

IN a letter published in NATURE of July 5, Mr. K. Hickman refers to the passing of the old academic feeling that there is something vaguely discreditable in a discovery which could be put to practical use. Relations between the universities and industry have undoubtedly become much closer in recent years, and increased contact has enhanced mutual respect, but there is still in some quarters a disinclination to accord to a piece of industrial research the same respect or academic recognition that would be paid to a similar research carried out in the university itself. The publication of scientific work carried out by industrial organisations of the type that Mr. Hickman cites will accelerate the passing of this attitude, although it must be admitted that industry in Great Britain is more reluctant to allow publication than is the case in the United States of America.

To leave all scientific research to industry would, however, be a dubious policy. There are large sections of industry where the value of scientific research is unrecognised, and there are other sections where the research department is still the first to be curtailed at any time of stringency. Even in those sections of industry where the most enlightened view of research prevails, in the main the lines of research which are undertaken must have some relation to production or economic possibilities. Few research workers in industry have not had repeatedly to pass by problems of scientific interest in favour of more urgent industrial ones. This inevitable limitation is recognised by some industrial firms, and an appreciable proportion of the purely scientific research carried out in British universities has probably been suggested or inspired by contact with industry. It may be a tragedy that the universities are unable to provide the whole environment of research, leisure and remuneration necessary to secure the best men to train young scientific workers for industry; it is no less a tragedy if they do not offer conditions which attract the best brains for a career of scientific research.

The realisation that the conditions and remuneration offered to those adopting a career of scientific research do not, to say the least, ensure attracting the ablest young men of science, or still more, in the absence of a definite bent, induce the most promising young men to undergo training in science in preference to training for careers

in law, medicine, or applied science, is responsible for much of the anxiety as to the position of fundamental research. There is no lack of candidates for positions in industry. Only in a few cases in recent years have the principals of technical colleges and similar institutions found themselves with more applications for graduates than they were able to supply. The unemployment situation, of course, affects the employment of science graduates in industry, and the existence of unemployment on a large scale in Europe seriously prejudices the employment of alien scientific workers anywhere. This is our reply to a correspondent from Bucharest, who, quoting the remark "not even a handsome salary has been able to attract a really first class organic chemist of the younger generation", from the leading article on "The Position of Fundamental Research" in NATURE of May 31, asks what prospects exist in Great Britain for an alien scientific worker fully qualified to occupy an academic or an industrial post. The engagement of an alien is quite naturally resented when unemployed nationals are available, and particularly when, as has frequently been the case, the alien is willing to accept a salary and conditions which scientific workers in Great Britain have declined.

The efforts of the British Association of Chemists have done something to redress the employment of alien chemists to the prejudice of British chemists. While no barrier exists to the engagement in industry of an alien chemist or other scientific worker, if it can be shown that he possesses special qualifications which are not possessed by available British workers, the Ministry of Labour, the permit and approval of which are required for any such appointment, is unlikely to sanction the engagement of an alien at a salary lower than that which a British man of science of equal standing could reasonably be expected to accept. Such a permit is, moreover, usually given for a limited period and on condition that a British chemist, for example, is appointed to study under the alien.

Purely scientific appointments would, of course, largely be influenced by similar considerations, and only an improvement in the general European employment situation and an abatement, through the efforts of the Committee on Intellectual Co-operation and others, of national prejudices, of which the growth of tariff barriers is only another example, is likely to promote the employment of scientific workers by other than their own nationals.

Discursive Meteorology.

Manual of Meteorology. By Sir Napier Shaw, with the assistance of Elaine Austin. Vol. 3: *The Physical Processes of Weather.* Pp. xxviii + 445. (Cambridge: At the University Press, 1930.) 36*s.* net.

THE New English Dictionary defines a manual as a small book for handy use, a concise treatise, an abridgment, a 'handbook'; 'often used as a title for books'. Probably the average reader thinks of a manual as a book of a systematic character, fairly complete and, probably, rather dry and colourless, kept at hand for information on any topic within its scope that may arise from time to time. But while Sir Napier Shaw is not careless in his choice of words, his book somewhat belies the hopes and the fears which its title might inspire; for it is both worse and better than this suggests.

On one hand, the work is far from being complete or systematic; but the author forestalls comment on this score, by a candid account of his thoughts while choosing a sub-title for this, the third of the four projected volumes of his manual:

"As far as may be" (he says) "we desire to give an insight into the physical processes that are operative in the control of weather. Our purpose is in fact to call the attention of the reader to the processes which can be recognized as physical, in the hope that he will be sufficiently interested to seek for any additional guidance that he may find necessary in the recognized treatises on the different parts of the subject. The achievement of that purpose implies the selection of a number of subjects from the recognized text-books on physics. Our presentation may be incomplete and disjointed, and for that reason a suggestion was made to define the scope of the volume with the title 'Miscellanea physica', but that was found to be more recondite than wise."

The title, however, does less than justice to the volume, in that much of the book is delightful 'popular' science, using the adjective in a wholly complimentary and respectful sense. Sir Napier is probably capable of doing for meteorology what Sir James Jeans and Sir Arthur Eddington have done for astronomy—make it a subject of keen intelligent interest to a considerable lay public, not by a mere recital of natural marvels, but by an attractive and simplified yet serious exposition of its progress and present problems. This, however, is not his object in the manual. His aim is rather to expound his subject in a wide discursive way, primarily for the benefit of the meteorologist and physicist; and though the book is not mathematical

in character, he does not shirk formulæ and difficult ideas. But he reverts frequently to fundamental principles—too often lost sight of during attacks on complicated problems—and often illuminates the mysteries of meteorology in a vivid and attractive way. In doing so he makes effective use, from time to time, of quotations from great writers of a past generation, with whose works present-day students may have little direct acquaintance.

The book is divided into ten chapters. The first three are only slightly connected with the remaining seven: they are devoted to gravity waves in water and air; sound waves; and atmospheric optics. They will be among the most interesting to the lay reader, because of the pleasant way in which they are treated: to the serious worker, however, they may appear superficial, omitting much that might, and perhaps should, be included in any general discussion of these topics. Another chapter (ix.) which stands slightly apart from the rest of the book is devoted to electrical energy in the atmosphere; this deals with atmospheric electricity and thunderstorms in an interesting way, without attempting to reconcile opposing views.

Here and there, in these and other chapters, the details are treated rather too casually, though usually with no serious ill result. Two examples must suffice: on p. 102 McLennan's work on the green auroral line is cited in a quotation from an article on the physics of the globe by another writer; here a direct reference to, or quotation from, McLennan himself would surely have been better. Again, on p. 74, in connexion with the blue of the sky, the size of molecules receives mention as follows: "Molecules are much smaller than the particles which form clouds. According to Rutherford and Geiger there are $\cdot 272 \times 10^{20}$ in a cubic centimetre. Whetham suggests that there are not more than ten million in a row of the length of a millimetre." The last sentence may leave the uninstructed reader with the impression that good authorities incline to think, but at present only tentatively, that the diameter of a molecule is not less than 10^{-8} cm.; but the middle sentence, which the physicist will recognise as referring to the number of molecules in a cubic centimetre of gas at normal temperature and pressure (in which actually the molecules are rather widely separated from each other), may seem to invoke the name of Rutherford in favour of a diameter rather larger than 10^{-7} cm.

A feature of the book is the considerable number of technical terms and usages adopted in it, many of them of the author's introduction. Every science requires its own technical terms and symbols, but one cannot always sympathise with the author's complaint of unsuitability and redundance in those of physics, on which he partly bases the advocacy of new terms and units. Some of his own usages arouse criticism, in particular, that of *tt* to denote absolute temperature (not only in the form 300° *tt*, but also in formulæ); why should not meteorologists adopt the now growing physical practice of writing 'K' to denote the Kelvin absolute scale, just as 'C' and 'F' are used for the Centigrade and Fahrenheit scales?

The scientific importance of the book must be judged, however, mainly with reference to the six chapters that deal with the atmosphere as a heat engine. Their scope and nature may be indicated by quotation of the chapter titles: Radiation and its problems; the controlling influence of radiation; air as worker; the liability of the environment; side-light on convexion and cloud; convexion in the general circulation (Ch. x.). It is impossible here to discuss these chapters in any detail, but the author may be congratulated on his courage in attempting an extraordinarily difficult task, and on the degree of success which he has achieved in it. The development of heat engines for industrial purposes has occupied large numbers of able minds for several generations, and despite all the facilities for experiment and trial, finality in this field still lies far ahead. The meteorologist is confronted with an infinitely more difficult problem, that of unravelling the workings of the atmospheric heat engine. Like the engineer, he has been forced to invent measuring instruments for the input and output of energy: the author has conferred a benefit in making a knowledge of this work, and its results, more readily available than would otherwise be the case. He shows how meteorological circumstances, themselves ultimately controlled by the supply of solar radiation, modify the effective input of this radiative energy into the atmosphere, by letting it reach the ground in some places and on some days, while in other cases it may be largely turned back into space by reflection from clouds without being able to exert much influence on the atmosphere.

The greatest difficulties that arise in the meteorologist's quest are those encountered when the influence of radiation on meteorology is examined, in conjunction with the secondary influences of the earth's spin, the distribution of land, water, and ice with the associated water vapour, and also the dust present in the air. Sir Napier here introduces us to "a succession of notes of interrogation; the

one undeniable achievement in that part of the subject " (dealing with the balance of radiation) " is apparently that within 2 per cent, by suitable redistribution, the radiation which is gained from the sun is lost again to space within the month ".

In attempting to trace the energy in its transformation in the atmosphere, it is necessary to combine the theory of heat and heat engines with hydrodynamical theory; in this volume, however, the author confines himself to " the assistance meteorology can expect from the theory of heat before making an appeal " (in volume 4) " to those universal providers the general equations of motion ". This may seem like presenting " Romeo and Juliet " with one of the two lovers left out of the play; but the author may justly reply that they are not together on the stage in every scene, and he has at any rate thrown valuable light on some of the heat processes in the atmosphere, by his discussion of them from the entropy point of view, using entropy-temperature diagrams. Opinions may differ as to the relative merits of different ways of regarding and representing a given set of facts, but in the present state of meteorology it is good to have the phenomena examined from many angles; in the application and development of his own special views and methods, Sir Napier here shows all his accustomed thoroughness.

In conclusion, a tribute of admiration and respect may be paid to the devotion with which the author has followed his chosen plan of gathering together into these volumes the knowledge gained in his long and active service to his science; his readers will hope ere long to see the completion of this work by the publication of the remaining volume.

Soil Genesis and Morphology.

The Great Soil Groups of the World and their Development. By Prof. Dr. K. D. Glinka. Translated from the German by C. F. Marbut. Pp. iv+235. (Ann Arbor, Mich.: Edwards Bros.; London: Thomas Murby and Co., 1928.) 15*s*. net.

TO paraphrase the words of Wurtz regarding chemistry, "Pedology is a Russian science; it was founded by Dokutschajeff of immortal memory". Such a statement would receive a much more general assent than that of Wurtz, because in no other science is the influence of one country so marked: the Russian names of some of the important soil groups have already become so anglicised that such a word as 'podsolised' is widely used and understood.

In recent years, much of the Russian work on soils has been made accessible to English-speaking people by the issue by the Russian Academy of Sciences of a series of bulletins in English; whilst their American colleagues have assisted in respect of the work of Gedroiz and Glinka. A large selection of the papers of the former has been translated and issued privately in a series of multigraphed bulletins dealing with soil chemistry and physics, and in the volume under consideration, Dr. Marbut has done the same for Glinka. This book deals with pure pedology—soil genesis and morphology—and is one of the first in English on the subject. As stated in the preface to the original, Glinka wrote it in German in order to bring Russian views on pedology before western readers. It was published in 1914, and no subsequent edition appears to have been published. In 1917, Ramann published his small book on the same subject based largely on Russian work: it was translated into English by Dr. C. L. Whittles in 1928, and these two translations appear to constitute the entire pedological library in English. Both belong to the pre-War period.

The post-War interest of English-speaking students in pedology has been greatly strengthened by the meetings of the International Society of Soil Science inaugurated in Rome in 1924: both Ramann and Glinka were present at the meeting, and the respect and affection in which they were held by all nationalities was memorable. Ramann, then an old man, died soon afterwards. Glinka, much younger, took an active part in the International Congress held in Washington in the summer of 1927, and was to have presided over that being held in Russia this month. His death in the November following the American meeting was a great loss to soil science and to a large number of friends in many countries.

Dr. Marbut has carried out his task of translation in a self-effacing manner. The original is faithfully followed, and there is an absence of editorial footnotes or square-bracketed insertions by which translators so often convey their own views. He has, however, found it necessary to translate the title according to American nomenclature, "Typen der Bodenbildung" becoming "Great Soil Groups". This is presumably due to an important difference in the meaning of 'soil type' as used by American and continental writers: the former use 'type' as the smallest subdivision in soil classification, and the latter as the largest. This unfortunate lack of uniformity has probably gone too far to correct. (It may be mentioned

that Great Britain is apparently following America as regards the use of 'soil-type').

The publishers are evidently not optimistic as to sales, as the book is multigraphed and not printed; only one side of the paper is used, and this results in a somewhat bulky volume, notwithstanding that the second part (120 pages), dealing with the soil-zones of Russia, is omitted altogether. The same applies to the 63 photographs and the soil map of Russia. It would have been well, perhaps, to mention these omissions in the translator's preface. More important and somewhat inconvenient is the absence of both table of contents and index.

As has been stated, the translation follows the original faithfully: its course is leisurely, space being found for a quotation nearly half a page long, from J. S. Mill, on classification.

The greater part of the book is devoted to *ektodynamomorphic* soils, that is, those in which climatic and other external factors in soil formation predominate over internal ones such as geological composition. Glinka accepts moisture conditions as the dominant factor in classification, and distinguishes six classes the moisture contents of which are optimum, average, moderate, insufficient, excessive, and temporarily excessive, respectively. *Endodynamomorphic* soils are those in which external factors have not yet exerted their full influence and which are therefore immature: they are dealt with only briefly.

The profiles are described with a wealth of morphological detail and are supported by a mass of analytical data almost bewildering in their profusion. It is to be hoped that future authors will give more guidance in interpreting such data, and will perhaps effect considerable economies in space. For example, it does not seem necessary to recalculate a long table of figures to show the results of analysis on an ignited basis as well as on the original soil, especially as no conclusions are drawn from them. The reviewer also hopes that the time is coming when the analysis of complete (unfractionated) soils will be a rare event. A soil can be separated into parts having various functions, and it is the analysis of the separated parts which alone can throw light on the relation of composition to properties and mode of formation. The analysis of a whole soil seems analogous to passing the whole body of an animal through a mincing machine and analysing the resulting mixture of bone, fluids, and soft parts, a procedure which would effectually conceal the facts of physiological chemistry.

The book will undoubtedly further the object of the translator in making the pioneer work of Glinka and the Russian school more widely known. It is to be hoped that it will also bring home to our own pedologists the lack of an original treatise in English on the subject, and so stimulate the production of a modern account of the soils of the British Empire.

Campbell Swinton's Reminiscences.

Autobiographical and other Writings. By Alan A. Campbell Swinton. Pp. ix + 181 + 18 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1930). 10*s*. 6*d*. net.

IN the preface to "Rob Roy" Sir Walter Scott remarks that no introduction can be more appropriate than an account of the singular character whose name is given on the title-page, who owed his fame in great measure to his residing on the very verge of the Highlands, and who possessed the advantage of descent from a clan famous for their misfortunes, and for the indomitable spirit with which they maintained themselves. Equally appropriate as an introduction to an enchanting story—though this time of men and things that have influenced the advance, during the last half-century, of physics and engineering—is the autobiography of Campbell Swinton. His kindly hand, that had just completed the writing of this book, has vanished; his friendly voice is still, yet his name will be perpetuated, not as he hoped in the legend of his descent, but in the useful part he took in the border struggle of natural science and its applications. Readers of this attractive volume of reminiscences may not all be acquainted with the fact that the author's thoughts were ever oscillating between the memory of his family's antiquity and the most recent activity in optics, telephony, turbines, or public affairs that required comment from him. His progenitors ranged through about eight centuries, from Hernulf son of Odard, son of Liulf. His happiest moments were when somebody could be beguiled into hinting that to refer too often to personal ancestry is to be a bore; for then he would laugh heartily, and cite the dictum of Silvanus Thompson, that all the élite of the intellectual world are bores, including ourselves.

Campbell Swinton was born in Edinburgh in 1863. He was educated there and in France, until eighteen years of age, when he came to England. His impressions of schoolboy life in a Scottish educational establishment remained to the end clear, penetrating, and embittered. He states in this volume that he "always loathed games, from earliest childhood", and he looked back with horror

upon the three years at a school where all spare time had to be given to compulsory games. Being the kind of boy he was, his school may have been an unfortunate choice on the part of his parents. In the next phase of his career, however, they made full amends by apprenticing him, in 1882, to Sir William Armstrong, for this gave to his activities full scope. Upon mechanical and electrical devices, photography, and the last word concerning the last miracle in natural phenomena, he was ever intent, but as he applied himself to mathematics with as little zest as he did to games, his movements were in some directions restricted. Nevertheless, as he possessed shrewd native knowledge of quantities, his judgment on broad issues was usually sound.

Those who knew Campbell Swinton best were aware that although he sought information in discourses at the Royal Society, the Royal Institution, and the Royal Society of Arts, about material things, his mind was set as much upon determining who's who as upon what's what. Circumstances, and his propensities, as well as his descent, brought him into the company of people of distinction and some of eminence. One consequence was that he accumulated anecdotes and photographs, many of which illustrate if they do not adorn this tale. His wide and intimate knowledge of the facts of progress, particularly of those relating to electrical science, render his contributions to history, here and there, very precious. For example, what he did in tribute to the work of David Hughes, and what he now has written concerning Graham Bell, Swan, R. W. Wood, Lane Fox, and Creed, shows with what perception and equity he could hold the balance. Concerning his own contributions he is modest and amusing, with the result that the autobiography is a fitting reminder of one who did much for his time, and did it pleasantly.

Photo-electric Cells.

Photo-electric Cells: their Properties, Use and Applications. By Norman Robert Campbell and Dorothy Ritchie. Pp. vii + 209. (London: Sir Isaac Pitman and Sons, Ltd., 1929.) 15*s*. net.

WITH the remarkable growth in the application of the photo-electric cell to almost all branches of industry, the need for a book dealing specially and fully with it has become increasingly acute. This want is now well filled by the publication of the volume under review. It is a striking fact that while the immense literature dealing with the selenium cell is concerned mainly with its use, the yet larger literature on the photo-electric effect is concerned almost entirely with theoretical considerations. As the authors state in their preface, the aim of their book is to redress the balance.

The subject matter falls naturally into three parts, which deal respectively with the theory and properties of photo-electric cells, their use, and their application to various special problems.

In the first part the authors have largely avoided the error of introducing too much theory—a fault which sometimes occurs in books which are essentially practical. We say 'fault' because it seems to us that the right place for general theoretical considerations is in a theoretical text-book, and that in a practical book on photo-electric cells only such general theory of the photo-electric effect as is essential to ensure the rational and most efficient use of the cell should be introduced. In the reasonable amount of theory given in Part 1 there are few criticisms that we would make; perhaps the most serious one is that the authors' statement that the photo-electrons are the 'free' electrons of the metal (p. 12) is not one which is generally accepted. Part 1 is crammed with useful information; Chapters v. and vi., dealing with the electric discharge and voltage current characteristics, are intensely interesting and need only to be read to be appreciated by those who use photo-electric cells. The last chapter in Part 1 is on the choice of a photo-electric cell, and here the authors' known preference for the vacuum rather than the gas-filled type is emphasised, perhaps too strongly. For though they admit that gas-filled cells are the only kind worthy of consideration for many important purposes, they say that they "need skilful handling, and are never wholly trustworthy"—a statement which seems rather exaggerated.

Anyone who intends to use photo-electric cells for the first time cannot possibly do better than read Part 2 of this book, where, after dealing with some general principles of their use, electrostatic and valve amplification circuits are discussed. The latter are specially interesting, although even already they do not represent the latest ideas, as Dr. Campbell showed at the recent joint meeting of the Physical and Optical Societies, when photo-electric cells were the subject under discussion.

In the third section, dealing with the applications of photo-electric cells, there are four chapters on the measurement of luminous flux, illumination, colour and light absorption.

There are extremely few misprints, and such small mistakes in an extremely valuable book can easily be rectified in a second edition, which we hope and expect will soon be necessary. F. C. T.

Our Bookshelf.

A German-English Technical and Scientific Dictionary. By A. Webel. Pp. xii + 887. (London: George Routledge and Sons, Ltd., 1930.) 36*s.* net.

THERE is every reason to suppose that this dictionary will quickly assume and long retain a place on the most easily accessible shelves of both private and public libraries. The translation of technical German is a task which falls frequently to the lot of scientific people: most of the members of the scientific professions probably have what is euphemistically called a 'reading knowledge' of the language (if they have not they would be wise to repair the omission), but probably comparatively few are in possession of an exhaustive and intimate acquaintance with the less common words and niceties of expression appropriate to their subject. To most people a good dictionary is frequently a necessity in ascertaining the exact meaning of technical expressions, and most people require that the dictionary shall not only serve their subject, but also be up-to date. It is sometimes alleged that the English equivalents of German technical terms are easily guessed, this is no doubt sometimes true, but more often a delusion and a snare, and in any event scientific people have little use for guesswork. Mr. Webel has provided us with a substantial book of reference, and he has striven to clarify the alternative technical meanings by indicating the branches in which they are used and sometimes by including formulæ, properties, or systematic nomenclature. The publishers, too, have seen to it that the type and paper are such as to be convenient in use.

The true test of a dictionary is, of course, service, and a reviewer can scarcely report critically on performance until he has used the book constantly for a long period. The vocabulary is, however, obviously fairly exhaustive as regards chemistry, mineralogy, and botany, and substantially adequate as regards general words and terms in allied and applied sciences. Random tests with a few dozen terms encountered in chemistry and chemical technology were highly satisfactory, except perhaps in one or two cases in the field common to chemistry and medicine. There are sixteen pages of abbreviations, and 143 pages of botanical names with their English and German equivalents. Every word has been provided with a five-figure code number. The author's friends were indeed well advised in persuading him to publish what was originally intended to be a private work of reference. A. A. E.

The Bridle of Pegasus: Studies in Magic, Mythology, and Folklore. By Warren R. Dawson. Pp. xv + 203. (London: Methuen and Co., Ltd., 1930.) 7*s.* 6*d.* net.

IN this volume Mr. Dawson has gathered together a number of essays on various subjects of cognate interest. Each deals with some manifestation of the magical idea in antiquity, usually in Egypt, which is then followed up in its historical setting to modern times. As will be anticipated by those who have followed Mr. Dawson's previous work, his subjects are for the most part connected more or less immediately with medicine and its practice. Thus one chapter deals with the use of the mummy as a drug—an interesting example of the working of the mind in transferring the supposed attributes of one substance to another under the influence of a magical concept. Another deals with the use of birthwort as an example of the progress of medical botany in twenty-three centuries.

The first two chapters are ingeniously suggestive. In the first the author deals with the rite of Amphidromia in Ancient Greece, in which the father on a certain day after a birth ran around the hearth with the child in his arms. This custom he brings into relation with the modern belief in the fairy changeling, and suggests that it was a test of the genuineness of the child. May it not have been something more, and does this explanation give full weight to the significance of the hearth? May it not have been both a test and a ceremony in the nature of bestowing the 'freedom' of the family on the new member. The second chapter suggests that the Harpies of Greek legend may have been a distorted memory of the great fruit-eating bats of India—an ingenious explanation of a curious example of the monstrous in Greek lore.

In dealing with nose-rubbing and salutations, Egyptian ritual practice is suggested as the origin of the kiss. The physiological explanation is set aside: but surely the author here ignores certain obvious facts. Even in smelling, to which the Egyptian philological evidence points as the original form of the salutation, there is a fundamental sexual and physiological element, which is strengthened in the transfer of the salute from the nose to the mouth. Both smelling and licking are so obviously gratificatory in the animal world that it is difficult to believe that in man the gratification—and there can be no question as to the fact—is derivative as a secondary character from a ceremonial practice.

The Terminology of Physical Science. By Dr. Duane Roller. Pp. 115. (Norman, Okla.: University of Oklahoma Press, 1929.) 1 dollar.

THIS little book, not much more than a pamphlet, is praiseworthy as an attempt to fill a gap increasingly felt as science teaching extends. It discusses the meaning of a number of terms found troublesome to the students of the physics department of the University of Oklahoma. The author also aims at simplifying innovations which have not yet gained general usage. Force, gravitation constant, radiation are examples of terms thus discussed, at greatest length. There are three shorter chapters on pronunciation, suffixes and prefixes, and the names of the elements—all quite elementary, but none the worse for that.

The book and its obvious utility remind one of the problem which is already serious in all countries where modern science is being taught to persons of another language and culture, for example, India, China, Egypt and other Arabic-speaking lands. Are such people to try to find equivalents in their

own speech for Western terms, or are they to adopt the original words of the founders and thus ultimately create a common fund of scientific terminology? There surely can be no two answers to this question. Every consideration, of clearness, of filiation to the original conception, of the community of men of science all over the world, points to the latter course. Dr. Roller's work should be an encouragement to those engaged in such classes to do something of the same kind. His is purely physical; no doubt in other branches other people elsewhere have tried the same thing. There was once a useful popular book by Stormonth on scientific terms. Is there a more recent work on similar lines? F. S. M.

X-rays. By Dr. B. L. Worsnop. (Methuen's Monographs on Physical Subjects.) Pp. ix + 101. (London: Methuen and Co., Ltd., 1930.) 2*s*. 6*d*. net.

IT is appropriate that one of the early volumes of Methuen's Monographs on Physical Subjects should deal with X-rays, which have proved so powerful a tool of modern physics in the elucidation of the fine structure of atoms and of the solid state. Whilst Dr. Worsnop's book gives a good general survey of the subject, it lacks the almost faddy attention to detail that one expects from an editor. For example, in the excellent bibliography of books, only one date is given, and in the text a reference appears as merely "*Physical Review*, 1923". The essential features of X-ray tubes could have been as well illustrated with the modern as with the old-fashioned sealed types (Figs. 1 and 2), in which the large spherical bulb prevents a close approach of one end of the collimating system to the focal region. Shearer and line-focus tubes are not mentioned.

Although a later volume in the series is devoted specifically to X-ray crystallography, the use of crystals as gratings for the study of X-rays is of such importance as to necessitate a brief account of some crystallographic details. These are not all explained so clearly as is desirable in a book intended for students. For example, a highly symmetrical arrangement of spots such as that shown in Fig. 7 is not an essential feature of a Laue photograph, since it is obtained only in very special circumstances. The section on crystal structure, pp. 24-26, should be rewritten with a clearer distinction between general results and those applicable only to orthogonal crystals. The final chapter wisely deals with the recent successful experiments on reflection, refraction, and ruled-grating diffraction in which the early attempts were failures.

Microscopic Pharmacognosy. By Prof. William Mansfield. Pp. x + 211. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1929.) 15*s*. net.

THIS work contains detailed descriptions of the minute structure of nearly a hundred of the more important vegetable drugs. The text consists of descriptions of the different tissues of the plants dealt with, the species being described under both botanical and pharmaceutical names. The species are divided into one of several main categories according to the part of the plant used—whether leaf, stem, root, or bark, etc. An important feature of the book is the clear full-page drawings of the anatomical structure of each plant described, which show the more important diagnostic characters.

As some of the plants dealt with are not official drugs, according to the U.S. Pharmacopœia, their inclusion in the work might be objected to on the ground that their exclusion would have made room for other more important drugs. However, as the space occupied by them is small and is devoted to such everyday substances as insect powder (*Chrysanthemum cinerariæfolium*), horehound (*Marrubium vulgare*), etc., their inclusion is not a serious matter. The work is a useful addition to the literature of medicinal botany, and will serve as an authoritative text in microscopic pharmacognosy for students of pharmacy and as a reference book for pharmacists and drug analysts.

Gari-Gari: der Ruf der afrikanischen Wildnis. Von Hugo Adolf Bernatzik. Pp. vii + 144 + 80 Tafeln. (Wien: L. W. Seidel und Sohn, 1930.) 10*s*.

IN this volume the author describes a journey through the Sudan in which he attained the ambition which had held him since his boyhood—a hunting and fishing expedition in Africa. His visit to the Sudanese tribes—Shilluk, Nuer, and Dinka—inspired him with an enthusiasm for the black man of the Sudan equal to his interest in its wild life. He describes their tribal life, their daily routine, their dances, and their festivals and feasts as he saw them, in something more than an impressionist spirit. While the book has no small merit as a description of the country and its people, its special attraction lies in its illustrations. These, 160 in number, in their happy choice of subject and in their technical excellence, form a collection which is probably unique in any printed book on the Sudan.

Experimental Physics: a Laboratory Manual. By Prof. A. E. Caswell. Pp. ix + 181. (New York: The Macmillan Co., 1928.) 6*s*.

ALTHOUGH it is usual for every teaching laboratory to have its own scheme of practical work, description of a course adopted elsewhere will often suggest useful changes either in general procedure or in the details of certain experiments. Prof. Caswell's book offers several such hints, notably for experiments in mechanics; impulse and momentum, and the general properties of machines are studied by two neat devices involving flowing water, the extension of a wire is measured by an optical lever method, and the density of air found from the mass of an old incandescent lamp before and after it has been cracked open. Two good calorimetric experiments are also described with ordinary gas burners, and an electrolytic method given for mapping fields of force.

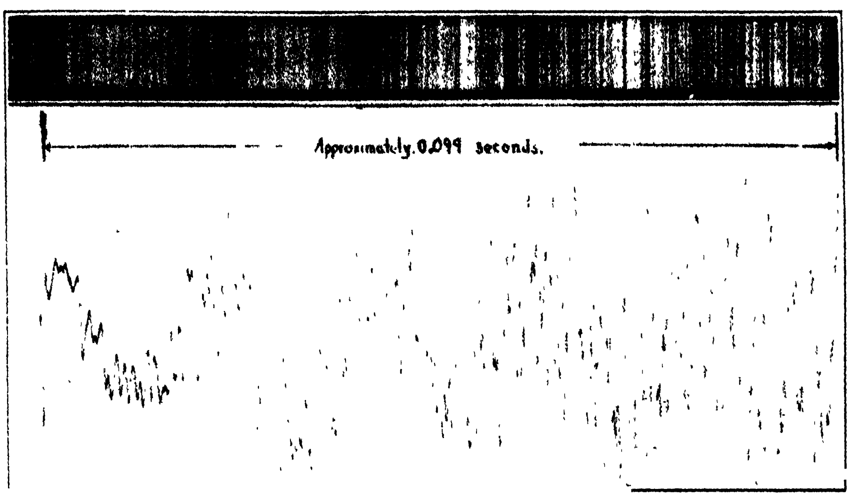
Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Microphotometric Analysis of Movietone Sound Records.

IT occurred to me while attending tests of a new modification of a fog alarm at Buffalo on Oct. 22, 1929, that use could be made of the 'Movietone camera' to obtain valuable information as to the nature of the signals and at the same time provide a permanent record for detailed study. A good instrument is nearly as sensitive as the human ear, and everything pertaining to the recorded sound is registered.

Some years ago I designed, but have not yet actually constructed, a sound unit of variable pitch, the emission of which may be recorded. It is based on the tunable diaphragm of variable frequency described in the *Journal of Scientific Instruments*.[1] The formula by means of which emission may be calculated can be found in a short article by me on the characteristics of telephone receivers.[2]



With such a sound standard at a known distance from the movietone microphone, a record of pitch and intensity of pure notes covering a wide range of frequencies and intensities may be recorded on the film immediately before and after the signal to be studied.

By passing the film through a Mohl microphotometer, as is done in the analysis of complex optical spectra, a record capable of interpretation in terms of intensity, quality, and frequency may be obtained.

Fig. 1 is a reproduction of a movietone film of an orchestra and the microphotometric record of the music recorded. I am indebted to the courtesy of Dr. G. O. Langstroth, of McGill University, for his skill in making the above Mohl record.

It is obvious that a more detailed study of this method of sound analysis and measurement is worthy of further study, not only in its application to the study of complex musical sounds, but also in the study of noise, so characteristic of our rapidly developing mechanical civilisation.

Formation of Streamers in Sedimentation.

DR. C. E. MARSHALL has recently described a method (*Proc. Roy. Soc.* A, 126, pp. 427-439; 1930) by which he claims that the size distribution of particles in a weak suspension of clay or similar material with particles of 2μ-$20\mu\mu$ diameter can be accurately determined. A high-speed laboratory centrifuge is used, each tube being nearly filled with a solution of cane-sugar or urea and a small quantity of the aqueous suspension (which has a lower density) is carefully poured on the top. A determination of the weight of sediment collected on the bottom of the tube in a measured time is used by Marshall to determine the weight of the particles which exceed a certain size, it being assumed that all the particles start from the top of the column at approximately the same time and settle through the solution in accordance with Stokes's Law. In discussing the method the author remarks: "It has not been found possible, so far, to apply these principles with any accuracy to the case of sedimentation under gravity. . . . Owing to slight variations in temperature or concentration the upper liquid sends down 'streamers' of suspension into the heavier liquid below." In advocating the use of the high-speed centrifuge he says: "The boundary between the two liquids actually becomes more sharply defined as centrifuging proceeds, and even if 'streamer' formation has begun, the liquid of low density moves rapidly back into place under its action."

We have repeated the experiments under gravity, and conclude that the explanation of 'streamer' formation is as follows.

As the sugar solution is denser than the suspension the system is initially stable. This stability is only transitory, however, as under the action of gravity the particles pass from the suspension through the interface and enter the sugar solution the uppermost layer of which, being now laden with particles, has a greater density than the rest. It consequently breaks up and 'streams' down through the clear solution. As long as the dense layer is reformed by the entrance of more particles into the sugar solution so long does streaming continue, with the result that many of the clay particles reach the bottom of the vessel very much sooner than if they had settled individually through a stationary solution in accordance with Stokes's Law.

Marshall's statement that streamers do not form during centrifuging is presumably based on the belief that the streamers have a *lower* density than the solution, which is clearly implied in the quotations given above. There appears to be no justification for this belief, and it is difficult to see why liquid lighter than the sugar solution should move rapidly downwards through it for many centimetres in a normal gravitational field. If, however, it be admitted that this streaming liquid is sugar solution containing particles and is therefore denser than the clear solution, it is very singular if it really "moves rapidly back" on centrifuging.

Naturally the arguments based on observed behaviour in a normal gravitation field cannot safely be transferred unaltered to the condition in the centrifugal field used in Marshall's method. A mathematical examination of the fate of the 'streamers' in the latter case presents great difficulties, but an

experimental examination is no doubt feasible. It is to be hoped that Dr. Marshall will be able to show that his ingenious method is not seriously affected by the point to which we have directed attention.

B. A. KEEN.
K. R. SCHOFIELD.
Rothamsted Experimental Station,
Harpenden.

MY belief that 'streamer' formation does not occur to any appreciable extent under the influence of the high-speed centrifuge is based on the following observations:

1. Since publishing the paper to which Dr. Keen and Dr. Schofield refer I have adapted the centrifuge to the determination of the fraction 2μ-1μ, by reducing its speed. This determination can be checked by the pipette method and a good agreement between the two has been found. Since 'streamer' formation would affect this fraction more than any other, the experimental evidence would appear to be against its playing an appreciable part.

2. If a clay is centrifuged for so short a time that the largest particles present can only traverse half the lower liquid, then a satisfactory boundary is found in approximately the calculated position, the lower half of the liquid remaining clear.

The above facts would appear to provide sufficient evidence that the centrifuge method is not affected by 'streamers'. The question as to the true explanation of 'streamer' formation under gravity is one on which I am not prepared to undertake a long investigation. It should be noted that the movement of the 'streamers' downwards under gravity does not exclude the operation of factors other than those considered by Keen and Schofield, and that it is still not certain that the 'streamers' are of greater density than the liquid in which they move.

The Feeding of Ammocœtes.

IN accounts of the Cyclostomata it is generally said that the Ammocœtes larva of the lamprey feeds by means of a current of water caused by the action of its pharyngeal cilia, and that food particles, entangled in mucus, are carried back to the gullet in the same way as in *Amphioxus* or in an Ascidian (cf. "Encycl. Britt.", 14th ed., art. Cyclostomata).

The presence of a mucus-secreting gland in the floor of the pharynx, and of a ciliated tract leading forward from the opening of this gland by way of lateral tracts—to a dorsal ciliated ridge, are arrangements so similar to those found in *Amphioxus* that it is natural to assume that they serve the same purpose, and in the same way, in both animals. When we add that Ammocœtes passes the whole of its life, until metamorphosis, buried in sand or mud, and that it has in its buccal hood a 'velum' and a straining apparatus in the form of tentacles, the resemblance seems almost complete.

During the last two years, I have had access to a fairly abundant supply of larval lampreys, and my observation of the living animals—confirmed by the examination of serial sections—makes it clear that their similarity to *Amphioxus* is deceptive.

The gill-bars of the larval lamprey bear no cilia that could cause a current of water through the pharynx. Indeed, a very cursory examination of a living animal, as it lies at rest, shows that the whole pharynx is in constant motion and acts as a muscular pump. Young larvæ (1 cm. to 2 cm. long) are transparent, and in them the action of the velum can be well observed under the microscope. The two velar folds execute a constant rhythmical movement, backwards and forwards, the right and left folds beating synchronously. The backward motion of one of these folds, seen from above or below, may be likened to the grasping or 'snatching' action of a hand in which the thumb is held parallel with the fingers. When a small larva is immersed in a suspension of Indian ink, and the pumping action of the pharynx temporarily ceases, it is seen that the velar movements alone can maintain a current of water through the pharynx.

I believe, however, that these movements have a second function. The ciliated tracts which sweep round the sides of the pharynx, to meet in the median

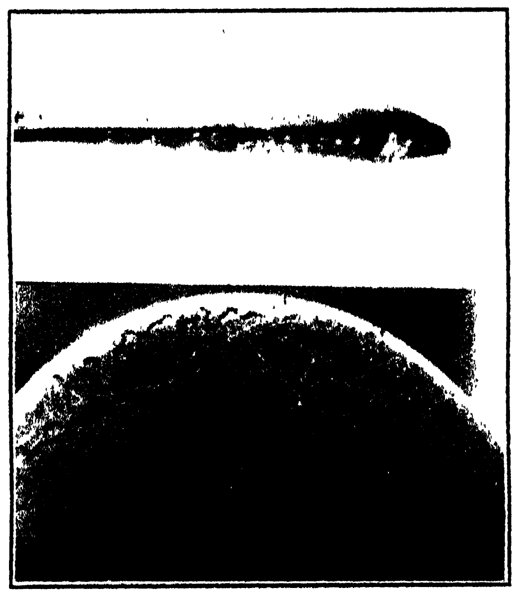

FIG. 1.—Above: a young larva fed on Indian ink and showing the blackened cord of mucus in its pharynx. Below: the burrows of young larvæ seen through the glass bottom of an aquarium.

dorsal ridge, take the form of grooves, each situated on the crest of a salient ridge. I have been able to demonstrate a ciliary current in these grooves, passing forwards and upwards, carrying mucus from the ventral gland. Now, the position and aspect of the lateral grooves place them in the trajectory of the edges of the velar folds when these folds execute their grasping movement; and in this way, I believe, the mucus is dislodged, to pass backwards in strands in the respiratory current.

What can be directly observed in the living animal, fed on Indian ink, is the formation of a single cord of blackened mucus passing down the middle of the pharynx to the gullet, the cilia of which haul it in rapidly, and pass it on to the 'stomach'. The front end of the blackened cord is frayed out into a hollow cone of strands, which in sections can be traced to the ciliated grooves. Thus the whole of the respiratory water with its suspended food particles must pass through a conical net of mucus strands before reaching the gill-clefts.

How strands of mucus, issuing from the circumpharyngeal grooves, become united into a single cord is not plain. The dorsal ciliated tract may initiate this, or a rotatory movement of the œsophageal cilia may twist the originally discrete strands together—but, so far, observation does not support either of these possibilities. What is certain is that the mucus cord, once established, lies quite free in the pharynx,

and does not move under the influence of dorsal cilia as in *Amphioxus*. In larger animals, which are not transparent, I have found it hitherto impossible to determine whether the feeding process is the same. The study of such animals killed while feeding on ink is unsatisfactory, and I propose to apply to them the method of radiography during an opaque meal.

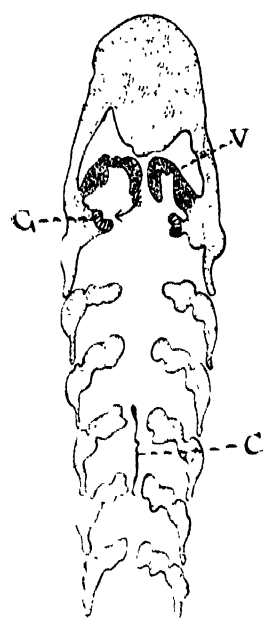

FIG. 2 Horizontal se the ant ior end of Amm

One other point may be mentioned. Though I have tried many times, and always in vain, to verify the existence of the neat U-shaped burrow, open at both ends, in which Ammocœtes is supposed to live, it is true that the animal's track in the sand or mud does persist for some distance as a tube the walls of which do not easily collapse. Ammocœtes appears to produce considerably more mucus in its pharyngeal gland than is used in feeding. Some of this mucus issues from the gills, and, in animals left in a glass dish without sand, tends after a time to become an encumbrance. In more natural surroundings it is removed by the friction of th d, the particles of which are at the same time cemented together. To this—rather than to a secretion from the skin—I attribute the formation of the burrow.

My drawing (Fig. 2) shows horizontal section through a young larva, and the letters *V*, *G*, and *C* indicate, respectively, the velum the ciliated groove, and the cord of mucus.

Phagocytosis of Internal Insect Parasites.

DR. W. R. THOMPSON, in NATURE of April 12, presents convincing arguments to the effect that living parasitic eggs and larvæ do not form centres of attraction for the phagocytes of their insect hosts. While this is doubtless true in the majority of cases, it would not appear to be an invariable rule.

A few years ago I made a somewhat intensive study into the bionomics of a number of Hymenopterous and Dipterous parasites of Noctuid larvæ (*Bulletin* 26, Dominion of Canada, Department of Agriculture, 1923). Among these were a number of species of the Tachinid genus *Gonia* which lay minute eggs on vegetation. When swallowed by a Noctuid larva the eggs hatch and the liberated larvæ ultimately pass through the wall of the mesenteron into the body cavity. Here they invariably succumb, enclosed within dense phagocytic cysts, unless they can rapidly travel to, and enter, the supra-œsophageal ganglion of the host. No feeding occurs until the ganglion has been entered.

I have dissected hundreds of unfed larvæ from the body cavity of their hosts. They were invariably surrounded by phagocytic cysts. Many of these larvæ were alive and moving within the cysts at the time of dissection. The latter were occasionally more than three times the diameter of the contained parasites. This would indicate that the foregathering of the phagocytes had commenced at least two days earlier.

Whether the surrounding phagocytes actually killed the enclosed larvæ I am not able to state with certainty. In so far as could be judged, encysted larvæ died within about four days after entering the body cavity. That death was not due to starvation is indicated by the fact that other larvæ have been found, in an unfed condition, still attached to the inner wall of the mesenteron, thirty days after the eggs had been swallowed. The subsequent life of the larvæ that reach the supra-œsophageal ganglion would indicate that they are well able to live a free life in the body cavity without succumbing to asphyxiation. It would thus appear that the rapid death of these small larvæ is due, in some manner, to their enclosure in a phagocytic cyst. It certainly presents an impassible barrier against their all-essential trip to the supra-œsophageal ganglion.

The more successful larvæ travel rapidly to the ganglion and remain here for a few days. During this period, for the first time, a little alimentation is found in their stomachs. They now re-enter the body cavity, where, for many days, they remain unattached to any host tissue and are simply floating in the blood. For as long as they remain healthy they are entirely 'disregarded' by the phagocytes.

Provided they are in a suitable host, these larvæ rarely succumb from any cause other than that of their destruction by fellow-parasites. Whenever superparasitism occurs one larva always attacks and destroys all rivals. After their death it was observed that phagocytic attraction to their dead bodies was less pronounced than it was to living, though unfed, larvæ that had not gained access to the supra-œsophageal ganglion.

Experiments were conducted, also, with the Braconid, *Meteorus vulgaris* Cress. Females of this Hymenopteron were induced to oviposit in Noctuid larvæ that were in varying stages of maturity.

In the case of the more immature hosts the eggs hatched and liberated larvæ which were not 'molested' by phagocytes except in the event of their death. When, however, *Meteorus* was induced to oviposit in host larvæ that were already contracting in preparation for pupation, it was found that, after three days, the eggs had increased in size as do all living eggs when introduced into the body cavity of a suitable host, but that they were all surrounded by dense phagocytic cysts. The embryos in these eggs were all dead when we made our dissections. In this case it is, therefore, possible that they had already succumbed before the phagocytes were attracted to the eggs, even though the enlargement of the latter indicates that they were viable after they had entered the body cavity of the hosts.

Mortality amongst Plants and its Bearing on Natural Selection.

IN his letter to NATURE, June 28, Dr. R. A. Fisher asserts that there is a concealed fallacy in my statement that "the mortality and therefore the operation of natural selection is almost entirely confined to the juvenile stages of development". But the reasons that he gives for this assertion would appear to involve a failure to distinguish between the effect of mortality on the number of offspring and its effect as a selective agent.

If I understand Dr. Fisher's contention aright it would be true only if the survivors at the later stage of development were an unselected sample of all the heritable variants present in the original progeny and

in the same proportions. Every seedling, for aught we have any right to assume to the contrary, is potentially capable under favourable conditions of attaining maturity and leaving progeny. But if 95 per cent of a species perish in the juvenile state the probability of an heritable variant surviving to leave offspring is only appreciable if the variation be associated with some feature of survival value in the seedling stage or has itself survival value at this phase of development.

Actually, so far as my observations on monocarpic species are concerned, and it was these I chiefly dealt with in my letter, mortality may be confined entirely to the juvenile state, or where death occurred at later stages there was considerable doubt as to its selective character. That the same may be true of polycarpic types is suggested by the extreme rarity or total absence in Nature of individuals of intermediate ages of arboreal species which have died from natural causes, although dead individuals in the seedling and senile phases are sufficiently familiar. In the monocarpic species at least there is the possibility that the question of the relative importance of any selective mortality at different stages of development does not arise, although, as Dr. Fisher rightly emphasises, mortality in the later stages will more profoundly affect the *number* of progeny produced than an equivalent mortality in the earlier.

Prof. MacBride in his interesting letter in NATURE of June 28 justly lays stress on the complexity of the factors involved in the survival of the early stages of development. May I mention one case in illustration of Prof. MacBride's very pertinent remark regarding the causes of survival, that doubtless in every particular case a special investigation would be required. The interesting endemic British plant *Helianthemum Breweri* has, as I have elsewhere pointed out, a peculiar mode of germination ("The Biological Equipment of Species in Relation to Competition", *Jour. Ecology*, 1929). Of the seeds shed by a particular individual at the same time some germinate in the autumn and the remainder in batches in a discontinuous manner of which the last may not germinate until late in the following spring. If the winter be a mild one, the first batch of seedlings will probably survive and by their priority of occupation compete successfully with those seedlings appearing later. If, however, there be a severe winter, all but the final batch may perish. Hence apart from selective mortality between individuals of the same batch the characters which here determine which age class shall be represented in the survivors will vary with the climatic conditions. This is a comparatively simple instance but indicates sufficiently the complexity of the problem of causation in selective survival.

Transmission of Potato Leaf Roll.

MAY I be permitted to comment on Dr. Whitehead's interesting letter appearing in NATURE of June 28, on the transmission of potato leaf roll by the aphis *Myzus circumflexus* Buckt? We are using this insect in our potato virus transmission experiments at Cambridge and have been doing so for some years. As regards its efficiency as a vector of potato leaf roll, I prefer to say nothing at present, as our experiments are still incomplete. I cannot, however, quite agree with Dr. Whitehead in his recommendation that *M. circumflexus* is a suitable insect for use in studies upon potato viruses, at least in respect to the mosaic group. I have found it a poor transmitter of potato mosaic, and moreover, the saliva contains a toxin—absent apparently in *Myzus persicæ*—which reacts upon several of the Solanaceous plants which we use in virus studies, including the potato. This aphis thus produces, by its feeding alone, a false 'mosaic' which is likely to mislead and confuse the inexperienced worker. Again, as regards the ease of identification of *M. circumflexus*, I would like to point out that the characteristic black markings on the back of the insect are liable to be very misleading. It is no uncommon thing for these markings to be entirely absent and we have had whole colonies of *M. circumflexus* in which the colour was a uniform green or pale yellow. In such cases, the differences to the casual eye between *M. circumflexus* and certain potato feeding aphides are not great.

Dr. Whitehead criticises potato virus workers in regard to their alleged preference for *Myzus persicæ* as the only insect vector of potato leaf roll. He will see in my paper on the insect transmission of potato leaf roll (*Ann. App. Biol.*, **16**, p. 14, No. 2, May 1929) that I state: "That it (*M. persicae*) is the only carrier of leaf roll is probably not the case." The importance attached to *Myzus persicæ*, which Dr. Whitehead deplores, in its relation to potato leaf roll is based on the following reasons:

(1) There is little doubt that it is the most efficient insect vector of potato leaf roll *among potato feeding insects*. (*M. circumflexus* is almost wholly a glass-house aphis.)

(2) *M. persicae* is one of the commonest aphides occurring on the potato, and in addition is an almost omnivorous feeder; it has been recorded from 52 plant hosts—a fact which, incidentally, renders it exceedingly suitable for virus transmission studies.

(3) Besides attacking the haulm of the potato, *M. persicae* is to be commonly found feeding upon the sprouted tuber in the store, and it is probable that much virus dissemination takes place by this insidious mode of attack. Finally, it is my opinion that *M. persicæ* has a definite affinity for the virus of potato leaf roll, but the evidence is still insufficient to allow of the conclusion that an absolute affinity exists such as appears to be the case between the virus of aster "yellows" for example and its insect vector, *Cicadula sexnotata* Fall.

Eyeball Movements in Tests of Visual Acuity.

IN all published accounts, to which I have access in physiological literature, of testing visual acuity by the discrimination of two points as two and not as one, there is no mention made of a factor which must assuredly play an important part. The three qualities usually considered are the angle subtended, the illumination, and the contrast between the points viewed and their background. In all the discussions which I have read it is tacitly assumed that the eyeball is fixed. Now we know that a limb, and the eyeball is physiologically a limb, cannot be kept in a position of rest unless it is at an extreme of movement, as when the knee is fully extended or when gravity alone determines the posture. The best marksman is aware of the tremor of his rifle when it is supported solely by muscular action; indeed physiological theory demands that such tremor must exist. By no possibility can we assume that the eyeball, held in any ordinary position by muscular action, is free from such tremor. The fact that tremor is not obvious does not proclaim

its absence; when it is obvious we speak of it as nystagmus. Microscopic examination of the pupil tells us that the inner iridic margin, to the observing naked eye apparently fixed, is really in a state of tremor of small amplitude. The only recognition of the possibility of this movement of the eyeball which I have found is an article "The Application of the Physiology of Color Vision in Modern Art", by Henry G. Keller and Prof. J. J. R. Macleod in *Popular Science Monthly*, November 1913:

"There can be little doubt that a great part of the peculiar impression produced by pointilism depends upon the slight movements which the eyeballs are constantly undergoing, even during our most intent fixation. This of course produces a certain amount of overlapping of the colors of the retina."

It is obvious that if the eyeball moves during the test fixation, simple geometrical deductions from the subtended angle of the two points cannot immediately be applied to the retinal elements affected.

When double stars are observed we have another disturbing factor, namely, the variable refraction of the air, which gives a further displacement of the images on the retina. W. A. OSBORNE.

The Crystal Structure of Hydrogen Iodide and its Relation with that of Xenon.

USING the apparatus already described (see NATURE, Mar. 22, vol. 125, p. 457; *Rend. Acc. Lincei*, vol. 11, p. 679), I was able to obtain good photograms of crystalline hydrogen iodide at about 170° C. An iron anticathode was used. The lines correspond to a face-centred cubic structure with lattice constant a 6·18 A. The cell contains 4 molecules hydrogen iodide; the calculated density is 3·59.

It is remarkable that the lattice constant of hydrogen iodide is practically identical with that of xenon as found by A. G. Nasini and myself (NATURE, Mar. 22). This confirms what we then pointed out, namely, that the ionic radius of I^- is identical or very near to the atomic radius of Xe, which was then calculated to be 2·18 A.

From our present determinations we deduce for I^- the same value, while from the metallic iodides Goldschmidt (Geochem. Verteilungsgesetze d. Elem., *Norsk. Vid. Ak.*, **7**; 1926) found 2·20 A. in very good agreement with ours. The dimensions of the HI-lattice seem to be determined by the I-ions only, since the empty spaces amply suffice for the location of the hydrogen ions, the radius of which is surely less than 0·6 A. (Natta: *Giorn. Chim. Ind. e Appl.*, **12**, 36; 1930; *Gazz. Chim. It.*, **58**, 356; 1928).

There appears to be a possibility of obtaining solid solutions between xenon and hydrogen iodide, which would be a first instance of a mixed lattice in which neutral atoms alternate with ions. G. NATTA.

Soldering Tungsten.

IT does not appear to be generally known that it is not difficult to solder metals to tungsten: Angerer states that Neusilber (German silver) can be used, but with this exception the general opinion seems to be that welding is the only practical method. In fact, there are a number of metals that will run on tungsten, of which gold, palladium, zinc, and (I believe) nickel are the most important.

Pure zinc is useless, since it crystallises afterwards and may be broken off again; any brass, however, that contains a fairly large percentage of zinc seems to be satisfactory. 'Tobin bronze', a common brazing alloy, is an example. German silver also sticks in virtue of the zinc it contains; it shares with brasses the disadvantages that if it be heated too long the zinc evaporates and renders it useless, and also that of course no joins so made can be baked out in vacuum work.

Gold seems to stick firmly, but does not run very easily as a rule, especially if the borax has once burnt off (borax is a suitable flux for all the metals tried). Palladium runs somewhat better, but it is difficult to get the work hot enough in a flame; it may be applied with an arc (35 volts are enough for small jobs), and neither flux nor reducing atmosphere is essential. Perhaps the most satisfactory method for general use is to apply some gold, using an oxy-coal-gas flame and borax, and then to wrap a little fine palladium wire round the gold, apply fresh borax, and reheat until the palladium has been melted into the gold; as a rule the alloy will then also have run over the whole join. The melting-point may be altered by this means, and the vapour pressure is in all cases very small; work can be glowed out at quite high temperatures.

A patent has been applied for to cover the use of palladium, but in any case this will not affect private work in laboratories. R. D'E. ATKINSON.

The First Spark Spectrum of Antimony.

WHILE investigating the relationship of the (sp) transition of the successive elements from indium to cæsium in their normal as well as ionised states, it was found that the data were insufficient. It was therefore proposed to investigate the necessary arc and spark spectra of the elements. The first uninvestigated element is antimony in the first state of ionisation. With the help of a one-metre concave grating set according to the Paschen-Runge mounting, I have photographed the entire spectrum from λ8500 to λ3000. The spectrum is analysed and identified as arising from the transitions ($P_1 \leftarrow P_2$), ($P_2 \leftarrow P_3$), and ($P_2 \leftarrow Q_1$). The lines $^3(P_2D_3)$, $^3(P_2P_2)$, $^3(P_2S_1)$ of the ($P_1 \leftarrow P_2$) transition are 12863, 16714, 19310 respectively. The difference $^3P_1 - {}^3P_2$ is 0·4814.

Gas Discharge Wave-length List in the Extreme Ultra-Violet.

WE have prepared a list, arranged in order of wave-length, of the published lines in the extreme ultra-violet (λ2500 to λ100) arising from discharges in gases. The elements included are hydrogen, helium, carbon, nitrogen, oxygen, neon, sodium, silicon, argon, and mercury. Thanks to support from the Carnegie Institution of Washington, it has been possible to publish a limited mimeographed edition of the list, copies of which have been sent to a few spectroscopists to whom we thought it might be of particular use. We should be glad to give copies to any others who may write requesting them. JANET M. MACINNES. JOSEPH C. BOYCE.

The Equi-Signal Zone Radio Beacon and Air Navigation.

By Dr. R. L. Smith-Rose.

THE application of directional wireless methods to assist aerial and marine navigation has been progressing steadily during the past few years. After passing a period of uncertainty as to its accuracy and reliability, the wireless direction-finder has established itself as a very useful aid to marine navigation. Many hundred ships of all nationalities are now fitted with direction-finders, and a large number of fixed beacon transmitting stations are now in operation in various parts of the world for the specific use of such direction-finding installations.

As an alternative means of obtaining wireless bearings, the rotating loop beacon developed in Great Britain by the Royal Air Force is now undergoing a full scale trial with the installation erected last year at Orfordness, Suffolk. The advantage possessed by this method of operation is that the whole of the directional part of the system is at the transmitting station on shore, and any ship fitted with a radio receiver can take bearings with the aid of a suitable watch or chronometer. From reports already received from various ships which have taken bearing observations upon the Orfordness rotating beacon, it appears that this method of obtaining bearings is likely to prove at least a very useful auxiliary to the wireless aids to marine navigation. A survey of the progress made of recent research on both the above methods of directional wireless and their application to marine navigation was given in a lecture before the Royal Institution, an abstract of which appears in NATURE for April 5 and 12.

In the search for a suitable means of applying directional wireless methods to aeroplanes, two points become of vital importance. The first is that any additional apparatus in the machine, such as a direction-finding installation, is objectionable from the point of view of the otherwise unnecessary weight which it entails. Secondly, the normal travelling speed of aircraft is so high that it is necessary that bearings should be obtainable as rapidly as possible. This factor seriously limits the utility of the rotating beacon method, since bearings on the system are only obtainable at half-minute intervals, during which the position of the machine may have changed by distances of the order of one mile. It is further desirable that the whole of the receiving and recording apparatus in the aeroplane should be as automatic as possible, in order to avoid the infliction of unnecessary duties upon the pilot or wireless operator.

To meet these objections of the ordinary methods of direction-finding, considerable attention has been devoted in the United States during the past six years to the development of a method of course-indicating by wireless, which was patented by O. Scheller in Germany in 1907. Scheller's patent covered essentially the use of a transmitting station which was provided with two equal directive aerial systems pointing in different directions. The transmitter was arranged to send alternately on each aerial two letters with complementary Morse characters, such as *A* (dot dash) on one aerial and *N* (dash dot) on the other. At a receiver situated anywhere on either of the bisectors of the angle between the aerials the two letters would be received at equal intensity and would form a continuous dash. If the receiver is moved to one side or the other of this direction, one letter would predominate and would indicate to the observer to which side the receiver was displaced. In this way the four directions of equal signal strength are well defined, and a ship or aeroplane keeping the two received signals of equal intensity would pursue a straight line course directed to or away from the transmitting station. During the War, attempts were made by E. Buchwald [1] to apply this method to assist the navigation of aeroplanes towards the transmitting station, which for the purpose was constructed with two inverted *L* aerials at an angle of 60° to each other. Some erratic results were obtained at first, due to the effect of the orientation and inclination to the horizon of the trailing wire antenna employed on the aeroplane. It was also found that the finite conductivity of the earth influenced the reliability of the results obtained.

In a later communication, F. Kiebitz [2] described further experiments made in the navigation of ships with this system of transmission. Difficulties were experienced due to a variation in the conductivity of the earth in the proximity of the transmitter, but it was ultimately found possible to obtain a sharply defined course along which the ship was navigated.

The system does not appear to have received further attention in Germany, but in 1924 a paper was published by F. H. Engel and F. W. Dunmore [3] which showed that attention was being devoted to this method of directional wireless by the U.S. Bureau of Standards. Since that date, and particularly during the past two years, considerable research and development of the application of this beacon system in the United States has taken place. The work has been largely carried out at or with the assistance of the Bureau of Standards for the Aeronautics Branch of the Department of Commerce. The technical results of the work have been described in a series of papers published in the *Proceedings* of the Institute of Radio Engineers and the Bureau of Standards *Journal of Research*, and the success of the system is evidenced by the recent proposal to establish a chain of some fifty directive beacons along the chief air routes of the United States.

The American type of radio beacon applies what is essentially Scheller's principle of directive transmission to two coil antennæ crossed at an angle of 135° to each other, the signals being transmitted alternately from each coil. The early type of beacon was supplied from a quenched spark transmitter, and distinctive Morse signals, such as *A* and *N*, were sent from each of the two coils

respectively. In the zone of equi-signals, these two Morse characters would merge or 'interlock' into a steady dash, which thus served as an aural signal to mark out the course defined by the beacon. The polar radiation diagram of each transmitting coil is of the familiar figure-of-eight form, and with two such coils crossed at right angles to each other it is evident that along the four lines bisecting the angles between the coil the equi-signal zones will be of equal strength. By changing the angle between the coils to 135° as stated above, two of the equi-signal zones provide stronger but less well defined signals than the other two. The quality of the equi-signal zone is usually specified by the width at a certain distance in which no inequality of the two sets of signals can be detected. The angular width of this zone for the experimental beacons already developed on the lines indicated below is of the order of 1° to 4°.

In a paper published in 1928 by Messrs. Dellinger and Pratt [4] the continued development of this type of beacon towards its present state is described in some detail. The first modification introduced was to employ two large fixed loops at right angles in place of the rotatable frame coils previously used, and to supply these coils with the necessary oscillatory current through a special type of goniometer. This goniometer comprised two primary coils fixed at right angles to each other and supplied with the necessary signal currents from the transmitter, and two secondary coils also fixed at right angles to each other, one coil being connected to each of the loop antennæ. Each of the two primary coils was supplied by one of the two sets of characteristic signals from the final 'push-pull' stage of the transmitter. The field created inside the goniometer by these primary coils was thus similar in form to the field radiated in space by the previous arrangement of frame coils. The secondary coils served to link up the fixed loop antennæ with this goniometer field and to reproduce it as a space radiation field. The advantage of this arrangement is that, by rotating the pair of primary coils relative to the pair of secondary coils inside the goniometer, the same effect is produced as that formerly obtained by rotating the frame coil antennæ. The whole installation thus enabled the equi-signal zones to be rotated in space by a setting of the goniometer.

The next important development in the course of the work concerned the elimination of the necessity for receiving an audible signal from the beacon. This has been accomplished by supplying each of the two phantom loop antennæ with current of the same carrier frequency but with a different modulation frequency. The modulation frequencies employed have been chosen at 65 and 87 cycles per second. This enables a mechanical vibrating reed to be used as a signal detector in place of the telephones, and by supplying two reeds adjusted to resonate at the two modulation frequencies mentioned above, a simple indicating instrument is provided by means of which the equality of the two signals radiated by the beacon is determined. Along any one of the four equi-signal zones radiated into space from the transmitter the intensity of the received modulation signal is the same on the two frequencies; both reeds of the indicator will therefore vibrate with the same amplitude. Immediately the receiver is displaced to one side or other of this course, the amplitude of one of the vibrating reeds becomes larger than the other. With the receiver and indicator mounted in an aeroplane, it is a simple matter to mark the indicating instrument in accordance with the direction to which the pilot must turn in order to get back on to the course marked out by the equi-signal zone.

By the employment of a third modulation frequency of about 108 cycles per second and a three section goniometer, it is possible to emit a space radiation field which has twelve directions of equal signals on one pair of modulation frequencies. If then the receiver is supplied with three pairs of vibrating reed indicators, it is possible to select each of these twelve courses in turn.

In the above discussion, it has been assumed that the electrical characteristics of each series of circuits in the goniometer and antenna loops are equal and that, therefore, the currents obtained at the various modulation frequencies are the same. If the currents in the antenna loops are made unequal, it becomes possible to alter the angle between adjacent zones of equal signal strength. A somewhat similar effect can be obtained by combining an open vertical antenna with the radiating loops in order to superpose a uniformly disturbed field upon the figure-of-eight polar fields generated by the loops. The possibilities of such combinations in providing means of varying the courses marked out by a beacon are described in a paper by Messrs. Dellinger and Diamond,[5] while a more detailed theoretical discussion of the methods of alining several courses from a beacon on this principle is given in later publications. This paper also contains an account of a method by which small amounts of shift in the course can be obtained by the adjustment of a suitable resistance in shunt to one of the vibrating reeds in the indicator installed in the aeroplane.

The practical application of the methods of alining four course beacons of the aural signalling type is described in a recent paper by F. G. Kear and W. G. Jackson.[6] These methods have been used in the alinement of three radio beacons to cover the air route from Cleveland, Ohio, to New York, a distance of about 400 miles. It appears from this paper, which was published in December 1929, that only the aural type of four-course radio beacon, or 'radio range' as it is termed in the paper, has so far been put into routine daily operation, although the visual type is nearing the end of its experimental development.

Concerning the operation of the type of radio beacon under discussion, reference may be made to an interesting paper published in 1928 by C. C. Shangraw [7] which describes the application of the visual type of two-course beacon by the United States Army Signal Corps, to a long distance flight of more than 2000 miles from San Francisco to Honolulu. A successful flight was made in August 1927 during which the operation of the special

beacons erected near the terminal points was found to be of great service. Over the central part of the course signals from both beacons could be heard, and it was estimated that at the distance of 1200 miles from Honolulu the width of the equi-signal zone was about eight miles, which indicates that the zone employed was unusually sharp (about 0·4°).

Some experiments carried out at an altitude of 2000 feet and described by H. Pratt indicate that at night the radio beacon system may be subject to erratic shift of the beacon course when the distance of transmission exceeds some fifty miles. In general, the changes in direction observed were less than 25°, but they were considered sufficiently serious to make the further study of this phase of the subject an urgent necessity. Apparently the errors are much reduced in magnitude by the use of a vertical antenna in the aeroplane, but this does not effect a complete cure and there will possibly be a limited range, of the order of about a hundred miles, over which this type of beacon may be considered to give results of the highest accuracy.

According to a recent publication,[8] the Airways Division of the U.S. Department of Commerce proposes to build fifty directive radio beacons of the aural signalling type in addition to the nine such stations already in operation. These beacons will all operate on a wave-length band 950-1050 metres (285-315 kilocycles per second) allotted by international agreement to beacon stations, and will be located along the main air routes at distances apart not exceeding 200 miles. In addition, these routes will be equipped with the low power non-directional 'marker' beacons which will give an aural signal to the pilot for a period of one or two minutes as he is flying overhead. These 'marker' beacons serve to inform the pilot as to his exact position along the course, and also to give him any local weather reports or other information of importance to the navigation of aircraft along the route in question.

Simultaneously with the development of these beacons special receiving equipment has been developed for use on the aeroplane. These receivers are designed to be sufficiently sensitive to work from the 6 ft. vertical aerial standardised for the aeroplane, and to give sufficient output for use with either the aural or visual methods of indication. Attention has been devoted to reducing the weight of the whole receiving equipment to the absolute minimum. It is likely that in the near future all mail and passenger carrying aeroplanes in the United States of America will be equipped with such receivers in order to make use of the extensive scheme of beacons now being erected for the specific purpose of assisting the navigation of aircraft.

The Second World Power Conference at Berlin.

THE Second Plenary World Power Conference which was held at Berlin on June 16–26 was probably one of the most ambitious and one of the most elaborately staged international meetings of recent years, and it is difficult on that account to follow with accuracy the main lines of development which were traced throughout the discussions. In the first place, the weight of documentary material was very large. Prior to the opening of the Conference, about 390 papers submitted by 37 or 38 countries had actually been printed and were available for examination; but during the Conference itself a number of additional papers appeared, mostly from Germany and Austria, with the result that the official collection will probably be rather more than 430. In addition to that, the principal scientific and technical associations in Germany and Austria, and, to some extent also, Russia, had prepared special monographs surveying the position in their respective territories. These monographs did not form an intrinsic part of the Conference, but they should be considered as an additional contribution to the information collected.

The delegates and members assembled at the various sessions totalled about 3900, while the papers were divided into 34 main sections corresponding roughly to the main aspects of national and international power development. During each full day six of these sections came up for examination at six meetings and the average number of speakers lay between 20 and 25, with, in certain cases, more than 30 taking part in the discussions. In all, therefore, during the period of the Conference, more than 1000 actual contributions were made to the work of assessing and judging the material submitted. These statistics are necessary to a comprehension of what might have been and what was actually achieved. In no case did discussion elicit any new information of value or record experiences which were not already described in the papers themselves, and, if one were able to bring the discussions into line with the actual documents, one would find considerable duplication and little real originality.

The importance of the Conference lay, therefore, not so much in any survey of the international power situation it attempted, as in the work of direct personal co-operation which took place unofficially before and after the Conference meetings. It also served to illustrate the reality of the industrial recovery which has taken place in Germany since 1924, since one important feature was the very extensive series of visits to German industrial works which was staged during and after the Conference. It is unnecessary to touch on this

side of its activities since the process of rationalisation and re-equipment of industry in Germany has been followed with great care by economists and by technical experts in Great Britain, and has already been fully recorded.

The Berlin Conference afforded an opportunity for discussion of the achievements of engineers from the principal industrial countries, and some decisions of value regarding British industry may well emerge from it.

The organisers of the Conference worked on a definite plan. They appreciated quite clearly the need for some degree of guidance throughout the complicated mass of material and arranged accordingly. Thus, the original papers were summarised in general reports extending to about 3000 words each. These reports numbered 34, were prepared each by a German engineer or industrialist, and they indicated what were the broad lines of progress and what were the most urgent questions still to be examined. In addition to this work of simplification, the main points of policy and of international progress were covered in a series of seven addresses arranged by the principal countries participating. Thus in the purely scientific sphere must be placed the addresses of Prof. Albert Einstein and Sir A. S. Eddington; in the purely administrative and economic those of Dr. Serruys on rationalisation and its latest forms, and Dr. Oskar Oliven on the Central European main transmission zone; in research considered generally the speech delivered by Mr. H. Foster Bain on the place of minerals in a power sustained world, and perhaps that of Dr. Vallauri on technical and general conditions governing the use of electricity. A seventh address which was due to be delivered by Mr. D. N. Dunlop, chairman of the International Executive Council, on the function performed by power in the evolution of the world, was not delivered owing to the sickness of its author; and in many ways it is a pity that this address could not be given, since, so far as one can understand from the summary given in advance, it did constitute a broad survey which might have served to have placed the details furnished by the original documents and by the discussions into an ordered design capable of immediate appreciation.

The weakness of this whole arrangement was undoubtedly to be found in the quantity of the original papers submitted, in the lack of uniformity shown by the reporters responsible for summarising those papers in the main sections, and for the lack of synthesis in the general addresses themselves. This observation does not apply to the contributions by Prof. Einstein and Sir A. S. Eddington, but it certainly applies to the remaining four speeches, and, through this circumstance, they had practically no value as a guide to deliberations during the Conference. The result was that the International Executive Committee passed no resolutions referring to the work of the Conference, even when arrangements are being made for a Third Plenary Conference to be held in America in 1936 and there may be a Sectional Conference at Stockholm in 1933—this latter still undecided. One was really unable to select from a mass of conflicting resolutions submitted by various countries any single resolution which would embody one contribution by the Second World Power Conference to the progress of power production and utilisation. That in itself is very significant and illustrates the inconclusive nature of the discussions which took place.

It was clear even at Berlin that technical progress in itself is now of less immediate importance than it was, and one felt a vague impression that something should really be done to bring discussions more closely into line with investigation of the real difficulties confronting electrical development and the growth of public utilities. One expert was courageous enough to state that in his opinion we had now reached a definite turning-point in this whole matter of power expansion. We had advanced so rapidly during the last few years that we had not yet taken the measure of that advance, and, through our inability to take that measure, we were in danger of embarking on unnecessary and costly experiment and of introducing a regime of economic as apart from technical inefficiency.

This observation can be confirmed, I think, by examination of the papers and to some extent also of the discussions: and the necessity for a real economic assessment of what has been achieved emerged more and more clearly as the Conference went on. One example of what I mean may be given. One German paper described the possibility of transmitting electrical energy at 380,000 volts pressure from Scandinavia to Germany. A general address given by Dr. Oliven outlined proposals for a European main-transmission system operating at 400,000 volts. At the present moment those proposals are quite fantastic; and they are fantastic not because they cannot be translated into practice technically, but because economic and political considerations are such as to rule them out. Even technically, we have no experience yet of operating conditions on a 380,000 volt circuit. It is in the regime of economics that the greatest obstacles are to be found. The transmission of electrical energy from Scandinavia to Germany would only justify itself if German resources proved themselves inadequate to the power consumption demand of the country, or if the exploitation of such resources were so expensive that it would pay to import electrical energy. It is obvious, however, that Germany would rather import energy from Switzerland, Austria, and even Italy through Switzerland, where it can tap existing power stations and fairly easily accessible existing power resources, than embark on a costly experiment across the Baltic.

The fundamental economic problems are to be found in the effective co-ordination of electrical power production and the control of the new main transmission systems evolved with the view of ensuring the maximum reliability of service and the maximum reduction in costs. Undoubtedly many technical experiments are being carried out. There was an impressive number of papers describing

power storage schemes built in Saxony and in the Ruhr, and in a number of European countries. Again, in the city of Berlin itself and in Hamburg, Diesel plants have been built of very large capacities to meet wide fluctuations in demand, in addition to existing steam power plant; while in Berlin again a steam accumulator battery at Charlottenburg has been attached to the peak-load station. In the Ruhr again, the gas pool created by the big iron and steel and coke oven plants has been in operation for some time. The technical problem appears, therefore, to be approaching solution; it is the administrative and economic which escapes definition.

There are indications also of a definite reaction against the theory of the big unit. There was less discussion in Berlin of giant power stations and giant power units than of the development of an economic load for such stations and such units. The development of such a load enters, at once, into the economic sphere and is inseparable from the consideration and assessment of the general economic activity ruling in the areas of supply. This brings the supply undertaking at once into touch with national economic problems and national economic prosperity.

The Berlin Conference was remarkably weak both in research and pure science contributions and in economic studies. It had a number of papers from the United States dealing with certain phases of power economics, especially in the elaboration of a sound price policy and in the definition of the various types of load, industrial or otherwise. But to give only one indication of what had become really urgent: the Conference failed to touch, even indirectly, on the following:

Whether it is more economic to close down fairly efficient medium-sized generating stations, aged ten years or more, none of which are being operated on a base load within an interconnected system, and build new stations with Diesel engines, or similar plant capable of interrupted operation without serious loss of efficiency?

The question here bears on depreciation factors, on the relation between the capitalised value of efficiency and the capital loss incurred by the closing down of such power stations and on the distribution of costs within the interconnected network itself. This is not a matter for mere calculation, it is really a matter for a genuine survey of the industrial and other potentialities of the area of supply. It is in the last degree the first movement towards a genuine economic assessment. The Conference made no effort to examine the problems in research advanced by C. F. Hirschfield in his paper "Research relating to Power Development" and avoided discussion of broad questions of industrial efficiency, rationalisation, and competitive efficiency based on power.

One outstanding requirement was really the co-ordination of essential information; while, at Berlin, statistical surveys of power resources were not given in any great number, owing to the general impression that preceding conferences had covered this side fairly adequately, yet there was almost a complete lack of statistics bearing on the utilisation of electricity, on the various types of power consumption, and on national productive capacity, measured with reference to power. One or two papers touched on this question tentatively; but this field is almost wholly virgin and requires to be cultivated before the next important forward movement can take place.

We are coming to the end of what might be regarded as a technical cycle and entering on the economic cycle. But, whereas in the case of the technical cycle, some background had actually been established merely through the process of evolution, no such background is available in the economic sphere. It may be objected that the general economic principles governing power production and consumption have not yet been formulated, and until they are formulated effective discussion of economic data is really impossible, but in the technical sphere the broad principles along which development is now taking place were not formulated in the first place. They were defined by purely empirical means and resulted from material experience. It was merely a case of trial and error.

The World Power Conference should find in the economic cycle its most valuable and most effective source of activity, and it should concentrate on this to the exclusion of almost everything else. It should examine all the possibilities of assessment on an economic basis; examine all the factors which govern the economic expansion of power production and consumption and link it up with general international industrial activity. It should aim at the standardisation of statistical forms and arrange for the exchange of essential data, drawn up in such a way that international comparisons can be carried out without difficulty.

HUGH QUIGLEY.

The Bristol Meeting of the British Association.

LOCAL ARRANGEMENTS.

AN interval of thirty-two years has passed since the British Association last met in Bristol. The 1930 meeting on Sept 3–10 under the presidency of Prof. F. O. Bower will be held in that city under conditions differing in many respects from those of the year 1898. In 1898 there was no University of Bristol and the Sections were housed in a scattered variety of buildings adapted for the purpose. Since that time, however, through the munificence of the Wills family, the University can provide within its walls accommodation for the reception room and general offices as well as for practically all the Sections. Moreover, the main buildings as architectural features form a landmark in the history of provincial universities.

A large attendance of members is anticipated, and amongst the foreign guests who have accepted invitations are the following in order of the Sections: *A*, Profs. Heisenberg, Siegbahn, F. Bloch, Van Vleck, Mulliken, Bureau; *B*, Prof. J. M. Hildebrand; *C*, Prof. Delepine; *D*, Prof. Van de Lange; *E*, Prof. A. E. Douglas; *F*, Prof. A. Plant; *G*, Prof. A. E. Kennelly, Herr Direktor W. E. Doerr; *K*, Profs. T. H. Goodspeed, F. A. F. Went, D. H. Campbell, W. J. V. Osterhout.

Two evening receptions will be given, one by the Lord Mayor in the Museum and Art Gallery on Sept. 4, and one by the Council of Clifton College on Sept. 8. In addition, garden parties will be offered by the University in the grounds of Wills Hall, by the Zoological Society of Bristol in the Clifton Zoo, and by the Hon. Mrs. Smyth at Ashton Court. Numerous visits to works, including the Avonmouth Docks, Messrs. Wills' tobacco factory, and Messrs. Fry's chocolate works, have been arranged.

The evening discourses are two in number. The first, on Sept. 6, is by Prof. E. V. Appleton on wireless echoes, and the second, by Dr. R. E. Slade, on the nitrogen industry and our food supply. In addition, public lectures have been arranged in Bristol and the surrounding district, including addresses by Sir Daniel Hall, Sir Josiah Stamp, and Sir Richard Gregory. A memorial lecture to a famous Bristol anthropologist, Dr. Beddoe, will also be given by Sir Arthur Keith.

The Bristol district is rich in features of historic, archæological, and scientific interest. In fact, owing to the wide choice of material considerable difficulty has been experienced in arranging excursions which do not omit points of special importance; but it is believed that all tastes have been catered for.

One interesting feature of the week will be a series of short tours during the day of historic Bristol and of the Avon Gorge and its vicinity. Also the list of sectional excursions is unusually large.

Like many large cities of to-day, Bristol is not blessed with a surplus of hotel accommodation, but the ancient city of Bath and also Weston-super-Mare are in easy distance of Bristol by car or train, and have special features which may appeal to many for the week of the meeting.

Obituary.

MR. VICTOR BRANFORD.

VICTOR BRANFORD, whose death on June 22 is widely regretted, was of an old East Anglian family; and his ancestry included descent from a sister of Sir Isaac Newton. In hard times his father had to part with his property, and he applied himself ably to a veterinary career, first as professor in Edinburgh, and then as consulting expert to the Army at the Cape. Victor and two of his brothers were so distinguished in mathematics at the University of Edinburgh as to be advised by Prof. Chrystal to take up that career; but he next took to chemistry and then to zoology and botany, and was for several years a successful coach. He also took active interest in the surveys of Edinburgh and Scotland then beginning at the Outlook Tower as a school and laboratory of social studies, and mainly prepared its comprehensive and comparative chart of general history.

Thus embarked on social study and exposition, Branford wrote for various magazines and reviews; and for a time he acted as editor of the *Dundee Advertiser*. He next camped for a season in the Highlands, spent some time on biology and social science at the University of Montpellier, and made observant visits to Switzerland and Italy, and later to South and North America, thence acquiring that combination of geographic observation with historic, economic, and social interpretation which characterised at once his practical life and his scientific career. Thus, turning to social finance, first as accountant and then as bankers' agent in the city, he early realised the important position and future of Paraguay, and became active towards its development, as a director and chairman of its railway, etc. From 1904 his ever-widening social knowledge and insight made him the active leader among the founders of the Sociological Society, and also its indefatigable secretary, first as editor of its 'Papers', and then of its *Sociological Review*, from its outset until the present number: and writing many of its most important contributions.

Branford's lectures in American universities were published as "Interpretations and Forecasts"; and his "Papers for the Present" led to "The Making of the Future" Series, with "The Coming Polity" and other volumes: which were next followed by "Living Religions" and by his comprehensive masterpiece of social synthesis and prevision, in glowing exposition—"Science and Sanctity". With Mrs. Branford (*née* Gurney), he established Leplay House as a home for the Sociological Society, and as part of the 'Sociological Trust', to which the residues of their socially expended fortunes have been essentially devoted, after provision for their two adopted sons. Here, then, is one of those still too rare careers—broadly akin to those of his old friends and the Society's successive presidents—Sir E. Brabrook, Frederic Harrison, Lords Bryce, Avebury, and Balfour, and Sir F. Younghusband—one and all conducting important affairs with many-sided scientific insight and socially philosophic advance, at once widely educative and inspiringly suggestive, since with ideas and purposes, thought and action harmonised in strenuous and generous lives.

Branford's still too rare preparation in mathematics, physical and biological science, through geography and history, and with active participation in current events, thus made his career of that high success which happily follows the sower and planter after his life-work is done; since anticipating that movement from the physical and natural sciences towards the social, which is again in progress.

P. G.

News and Views.

The seventh annual report of the Grand Council of the British Empire Cancer Campaign, which was presented at the annual meeting on July 14, indicates that the organisation continues to give useful support to cancer research in a variety of ways and at a number of centres. About £28,000 has been expended on topics which cover the whole range of the cancer problem, including the treatment of human cancer with radium at one end and fundamental work on tissue growth and plant viruses at the other. No striking new discovery of importance is announced in the summary of the different inquiries given in the report, but everywhere there is gratifying progress of the detailed kind that is useful and interesting to specialists. At the Fulham Cancer Hospital, Drs. Kennaway and Hieger have been tracking down the carcinogenic activity of tar through the fluorescent spectra of active preparations (see Nature, June 21, p. 932), and it looks quite likely that they may succeed in identifying the elusive substance or substances to which tar, shale oil, and the like owe their property of causing malignant tumours of the skin. At Leeds, Dr. Berenblum has continued his study of various skin irritants and has reached the rather remarkable conclusion that concurrent irritation with two different agents may be less effective than either of them by itself. From Sheffield, Prof. Mellanby reports that the greasiness of an animal's skin has a considerable influence on the facility with which repeated applications of tar cause cancer, which is perhaps one of the reasons why cancer of the skin is so much more frequent in the lower than in the higher social grades. On the whole, the theory that cancer is caused by a virus capable of transmission from one individual to another seems to be losing ground. Attention is being concentrated more on (1) the action of external irritating agents and the relation between cancer and occupation; and (2) the efficacy of radium and penetrating X-rays in the treatment of established human cases of the disease.

Prof. Elliot Smith has recently expressed the opinion (*Times*, June 26) that Peking man, furnishing a connecting link between *Pithecanthropus* and the Piltdown skull, "added stability to our conception of the qualities likely to be found in the earliest common ancestor of all three, the as yet undiscovered Pliocene Man". He went on to say that Peking man "afforded new and emphatic testimony of the closeness of the kinship of man and anthropoid apes". Prof. Elliot Smith's views afford an interesting commentary on those put forward by Prof. Fairfield Osborn in his presidential address to the American Association for the advancement of Science in December last (see Nature, Jan. 11, pp. 53-57). Prof. Osborn, accepting the Upper Pliocene date claimed by some for the Piltdown skull, regards it as confirming his prophecy of the discovery of a large-brained tertiary man, and also as supporting his conception of a 'Dawn Man' separating from the anthropoid stock in pre-Miocene times before the specialised adaptation of the Miocene anthropoids to arboreal conditions. In holding these views Prof. Osborn is in opposition to the theory of Darwin and his followers that man has arisen from an anthropoid ape not higher in the scale than a chimpanzee, which, however, he admits is held by "all the leading and most brilliant men of our time". The case against Prof. Osborn's view that the evolution accompanying the change from arboreal to terrestrial conditions on the generally accepted ape-man hypothesis involves an impossible reversion from the highly specialised characters of the miocene anthropoids to the more generalised characters of the human stock is ably stated by Prof. W. K. Gregory in *Human Biology* for May last. He there points out certain considerations against Prof. Osborn's inferences from the change in the relative length of the limbs in man and in the anthropoids, and suggests that he has ignored the essentially gorilla-like underlying character of the human hand and foot notwithstanding differences in form.

In taking *Eoanthropus* as his big "brained" tertiary man, Prof. Osborn cited as evidence of Piltdown man's ability to make use of that brain and of his skill with his hands the flints of tertiary age discovered in East Anglia by Mr. Reid Moir. In a letter we have received from Mr. Lewis Abbott, he suggests that the arguments of Prof. Osborn and other palæontologists might be much reinforced did they make greater use of the collateral evidence afforded by archæology and what is called by some 'lithoclassiology' a term which we cannot regard with complacence. Mr. Abbott rightly dwells upon the importance of the East Anglian evidence in any discussion relating to the antiquity of man, and especially of tertiary man, and enumerates some of the finds which might have gone to strengthen Prof. Osborn's case. He refers to the first "indisputable" find - the stiletto made from the base of a deer's antler found in the Corraline Crag at Allborough, Suffolk, some fifty years ago. A well-made flint implement was found in the Foxhall Crag pit, Ipswich, in 1888. This is the pit which was afterwards the site of Mr. Reid Moir's discoveries. At Thorpe Neswick several worked flints were found while digging out the rib of an elephant, and were accepted by the late H. B. Woodward--a very cautious observer--as of human workmanship. Mr. Abbott also refers to the finds made by Mr. Savin and others in the Cromer Forest Bed. These flints were first brought to light at Runton in 1888 on the same occasion as the finds at the Foxhall pit, during the East Anglian Excursion of the International Congress of Geologists, when the party had been joined by the principal East Anglian geologists. Mr. Savin resumed work on the Cromer Forest Bed in 1895, and an exhibition of his finds was held at Burlington House, arousing much interest. These finds, Mr. Abbott points out, show that evidence

for tertiary man had been obtained from the Forest Bed thirty-one years, and from the Corraline Crag thirty-nine years, before the date claimed by Prof. Osborn.

THE Ministry for Social Welfare in Austria has been carrying out observations with the aid of Prof. Conrad, Prof. Hausmann, and others, on the climatic conditions of sanatoria, in order that these should be placed in the best positions; for example, at mountain altitudes, where the maximal degree of sunshine and snowshine and cool dry air free from much wind are obtainable. Measurements of the ultra-violet radiation and of the cooling power of the air as indicated by the kata-thermometer, have been taken in addition to the usual meteorological measurements. In Britain the most sunshine and driest climate are obtained on the south-east, but sanatoria are scattered all over the country. No doubt the most ideal conditions are afforded by the Alpine climate, but excellent results can be obtained in the various parts of Britain by open air treatment. Shelters can be arranged to mitigate wind and artificial sunlight used to make up for deficiency of light. Even in Salford, rickety, weakly children have been made robust and healthy by being put to live in an open air shelter and playground, well clothed and fed, and given no artificial heat other than that used for drying clothes and warming food. For adults who cannot be disciplined as children, there is advantage in treatment at an isolated Alpine sanatorium. If cases of tuberculosis of the lungs went there in the early stages of the disease and stayed for a couple of years, so as to avoid catarrhal infections which result from coming home, cure would result in almost all. Mischief is caused at the sanatoria in popular Alpine resorts by the winter visitors carrying thither catarrhal infections. Isolation from such infection is a chief requirement while the warm sun and calm, cold, clean air of the mountains works its effect.

THE presidential address of Mr. Edwin Thompson, chairman of the Water Committee of the Liverpool Corporation, at the annual meeting on July 9 of the British Waterworks Association, was an interesting discursive survey of various matters connected with the supply of water to cities and towns generally, with some allusion in particular to certain notable features and incidents, historic and economic, in the genesis and development of the waterworks of the City of Liverpool. In the course of his address, Mr. Thompson touched upon the chemical analysis of water, river pollution, supplies from wells, methods of purification, hardness, water for power purposes, per capita consumption, domestic fittings: in fact, on quite a number of topics of importance to municipal authorities. Among points of interest may be noted his statement that the consumption of water in Liverpool is 36 gallons per head per day, and his confident anticipation "that the time is not far distant when the demand will be much greater than it is to-day and that it will become a very serious consideration". He went on to contrast the low quantitative standard of British supplies with that obtaining in America (200 gallons per head per day) and the defects in Great Britain in regard to fittings for domestic water supply. Liverpool, it appears, was probably one of the first authorities to require no additional payment for water for water-closets and baths, the extra charges for these purposes being done away with in 1860. The cost of providing and maintaining all communicating pipes supplying domestic services in the Liverpool area of distribution is more than £7500 per annum, and for this there is no direct charge. Finally, Mr. Thompson gave it as his opinion that, in spite of national shortcomings in other directions, "when it comes to the question of the purity of public water supplies Great Britain stands pre-eminent".

THE Water Power Resources Committee in its final report issued in 1921 recommended that investigation should be made into the problem of compensation water to riparian interests and appointed a sub-committee to inquire into the problem. The present method was adopted some seventy years ago and based on purely empirical lines. The procedure is to deduct from the average annual rainfall over the catchment area one-fifth or one-sixth in order to arrive at the rainfall that might be relied on during a period of three consecutive dry years. From the remainder 14 inches was deducted to cover losses due to evaporation and absorption. The amount thus reached, called the available yield, was divided between the needs of public water supply and riparian interests in certain proportions, generally two to the former, and one to the latter. The sub-committee (Assessment of Compensation Water, Ministry of Health, 1930) proposes to retain the method of estimating rainfall over three dry years by deducting 20 per cent from the long period average, but to alter the basis of allowance for evaporation and absorption. It is proposed that this loss should be measured for every river by the difference between the rainfall and the run off as ascertained by stream gaugings, which should measure all flows of the stream for a period of seven years. This period should be prior to or during the construction of impounding works. From this a method is suggested for arriving at the assessable flow on which the amount of compensation water should be determined in relation to the use of the stream by riparian interests.

FROM a communication in the *Times* by the curator of Sir John Soane's Museum, the welcome news is forthcoming of the recovery of thirty-two large drawings by Sir Christopher Wren, the details of which refer to Whitehall Palace (1698), Windsor Castle (1705), and Greenwich Hospital (1694–99). The drawings had found a home at All Souls, Oxford, though no record existed respecting their acquisition. The first dispersal of the collection of "Drawings of Architecture of the late Sir Christopher Wren", together with a series of antique marbles, gems, medallions, and other articles, took place in the Great Piazza, Covent Garden, in April 1749. A sale catalogue mentions the recovered drawings; also, a note therein gives the purchaser's name as Dr. Stack, F.R.S. This interested person would appear to be identifiable as Dr. Thomas Stack, who was elected into the Royal Society on

Jan. 26, 1737 [1738 N.S.], signing the charter book on formal admission a little later. At that time Sir Hans Sloane was president of the Society. If one may judge from a paper of his in the *Philosophical Transactions* for 1739, he seems to have been of a credulous turn of mind. Perhaps better opportunity was given in work connected with the writings of the celebrated Dr. Richard Mead (Newton's physician). He translated from the Latin, Mead's "Treatise concerning the influence of the Sun and Moon upon Human Bodies" (1748) and "Medical Precepts and Cautions" (1751). Posterity now connects him, however indirectly, with All Souls, Oxford.

DURING the World Power Conference held in Berlin last month a visit was arranged to the new high-tension testing room of the well-known porcelain factory of Messrs. Ph. Rosenthal and Co., Ltd., in Bavaria. The rapid increase in the high-tension voltages used in practice has made necessary the use of high-tension testing pressures of two million volts. In Germany 220 and 360 kilovolts are at present in use, and for the European grid Dr. Oliven has proposed 400. As the firm manufactures high-tension insulators it was necessary to test with very high pressures so as to increase the knowledge of sparking phenomena. It had the benefit of the experience gained in similar laboratories in other countries. The building is of reinforced concrete; it has no windows and has a flat roof. It was necessary to make the room lightproof, so that photographic studies could be made. Two independent sets are installed, one for alternating current and the other for direct current impulse testing. The firm has succeeded in building a single transformer which produces two million volts. The height of the transformer is 26 feet and the voltage produced is measured by the sparking gap between two hollow copper spheres, each eight feet in diameter and weighing 1600 lb. The direct current impulse plant is the largest in existence. When the condensers are connected in series a voltage of 2,200,000 is produced. The spherical electrodes, five feet in diameter, are arranged so that the spark gap is vertical, and thus floor space is saved. Photographs of the outside and inside of the testing laboratory are given in the *Electrician* for July 4. It is said to be a most impressive sight to see the flash-over on an insulation chain, composed of 14 large insulators, the spark attaining lengths up to 12 feet.

IT is announced by Science Service, of Washington, D.C., that a bill is shortly to be reported out from the House committee on the Library which will allow the President of the United States to decorate men and women who, while in the employ of the Federal Government, have "made outstanding contributions to the advancement of scientific knowledge or the application of its truths in a practical way for the welfare of the human race, and to citizens who, while in the employ of the Federal Government, have rendered conspicuous service to humanity at the voluntary risk of life or health over and above the ordinary risks of duty." There will be two medals. For the scientific worker who has made a specific contribution to the knowledge of the world, there will be the Thomas Jefferson Medal of Honour for Distinguished Work in Science. This medal is named after President Jefferson, who was an early patron of science. The other medal will be known as the Jesse W. Lazear Medal of Honour for Distinguished Self-Sacrifice for Humanity, and will be awarded to those who risk life and health that the cause of science may be advanced. This medal is named after Dr. Lazear, who, as a member of the famous Yellow Fever Commission, allowed an infected mosquito to bite him, giving him a fatal infection with the disease, which has been conquered through the information that this and similar heroic sacrifices have given to medical science. Only three medals in each class will be awarded each year by terms of this bill, and the National Academy of Sciences will pass on names recommended to it by heads of departments and independent offices of the Government. It is conceivable that one person might be awarded both medals, either in one year or in different years. Recipients of these medals would, in addition, receive 1000 dollars each. The bill will probably pass at the next session of the 71st Congress, beginning in December.

MESSRS. Adam Hilger, Ltd., have just published a new edition of their general catalogue, containing particulars of apparatus in sections D to X of their complete list and a statement of the contents of supplementary catalogues of more specialised manufactures. It includes a considerable number of items, marked as now appearing for the first time, of which a few may be specially noticed. In Section E (spectrographs) there is a description of a 1-metre vacuum grating spectrograph following the lines laid down by Sawyer (*J.O.S.A.*, 15, p. 303: 1927) and also embodying features not appearing in his design, such as an efficient means of raising or lowering the plate-holder and of withdrawing and replacing the shutter of the plate-holder *in vacuo* so that the instrument may be used in a well-lighted room. The slit system is arranged so that gas discharge spectra may be photographed without using a window. In the same section an X-ray crystallograph is described, designed for chemists, metallurgists, geologists, and others who desire the analysis of crystalline structure in comparatively short periods of time and with the smallest amount of unfamiliar technique. Section F (accessories for spectrometers and spectrographs) includes a new apparatus for sparking solutions in which the liquid drops steadily from an upper tube into the spark gap. It would have been of advantage if it had been stated whether the window supplied was of glass or quartz. Arrangements for carrying out de Gramont's method of sparking materials, including powders, are also provided, and a special powder has been prepared containing fifty elements in such proportions as to show only about seven spectrum lines, including the *raies ultimes*, of each element. This should greatly facilitate spectrum analysis. A star-plate measuring machine, accommodating plates up to seven inches square, is described and illustrated in

Section L (micrometers, etc.), and Section M (polarimeters and refractometers) contains particulars of an ultra-violet étalon refractometer requiring only a thin film of liquid. The catalogue as a whole shows a very adequate provision for all types of spectroscopic and allied investigations.

IN his seventeenth annual report to the board of trustees of Mellon Institute of Industrial Research of the University of Pittsburgh, Dr. E. R. Weidlein has summarised the activities of the institution during the fiscal year ended Feb. 28 last. The sum of £186,000 was contributed by industrial fellowship donors in support of research - an increase of £26,000 over the preceding year. The total amount of money appropriated to the Institute by companies and associations for the nineteen years ended Feb. 28, 1930, was 6,749,273 dollars. Throughout the year 71 industrial fellowships, requiring the services of 209 full-time research men, were in operation. Sixty-one industrial fellowships - 21 multiple fellowships and 40 individual fellowships - were active at the beginning of the new fiscal year. Eight are being sustained by industrial associations. The industrial research personnel consists of 21 senior industrial fellows, 88 industrial fellows, 34 full-time fellowship assistants, and a number of part-time assistants. Especially notable results have been forthcoming from the following investigations: air pollution, bricklaying, carbonated beverages, cooking utensils, food varieties, heat insulation, iodine, laundering, organic synthesis, petroleum production, and vitrified sewer pipe. Ten fellowships completed their research programmes: beds, cast iron (two fellowships), chrome plating of aluminium, gum, hats, industrial alcohol, licorice, stearic acid, and surgical supplies. Nine fellowships became active during the fiscal year: can, fatty acid uses, garment, hemp paper, nicotine, oxygen, rosin oil, steel treatment, and wood by-products. Five new fellowships have been accepted and their operation will be begun during the early part of the new fiscal year. The Institute's department of research in pure chemistry has continued its work on acidic carbohydrates occurring in plants and on other problems in the province of sugar chemistry. Of the 61 fellowships now active, 15 have completed more than ten years of work.

IN pursuance of its policy of founding meteorological and geophysical observatories in high latitudes, the Soviet Government last year sent an expedition in the icebreaker *Sedov* to found an observatory in Franz Josef Land. After some trouble with pack-ice Cape Flora was reached and eventually Hooker Island, where a site was chosen on the west coast in lat. 80° 19′ N., long. 52° 48′ E. Prof. R. Samoilowitch gives an account of the work of the *Sedov* in *Petermanns Mitteilungen*, Hefte 5-6, 1930, with a track chart and a map of Hooker Island. The *Sedov* pushed north to the Victoria Sea and visited Rudolf Island before returning to Archangel. This station is the most northerly observatory functioning.

FROM the Annual Report of the National Museum of Wales it is easy to discover the secret of the recent progress of that institution. Here is a national museum in more than name, for its governing body embraces the widest interests and the nation unites behind it with a will. During the year the Building Fund received from private donors £10,487, and £57,000 has been accumulated towards the erection of much-needed new galleries and a lecture room. The total aimed at is £150,000, and of this the Government has promised £50,000; pending the raising of this large sum, the Government has permitted a proportional expenditure of grants, and the building of gallery and reserve accommodation in an east wing is being proceeded with. In the Museum itself the gradual purchase of new exhibition cases is making itself noticed, both in permitting the addition of new objects of interest and in improving the general appearance of the exhibits by allowing the elimination of old ill-assorted cases.

THE city of Vancouver, British Columbia, has reason to thank its Art, Historical, and Scientific Association for the efforts made to increase public interest in the Museum and Art Gallery. The publication of the quarterly *Museum and Art Notes* should be good propaganda, for the journal contains a proper blend of articles of general interest and of more definite scientific value. The results are apparent enough in the response of the public. The Curator's report for 1929 (contained in the December *Notes*) shows an attendance of 86,228, an increase of almost 10,000 in two years, and the acting president's address states that although every section, art, natural history, mineralogy, Indian, etc., has attracted its following of students, residents, and tourists, the outstanding feature has been the greatly increased use of the Museum by school children, both individually and in classes conducted by the teacher and, where requested, by the curator. But there is a fly in the ointment: valuable collections have been lost to the museum because of lack of space and funds to exhibit them suitably, and material which has been given by generous donors is crowded out of the galleries. More accommodation is required, and the city authorities would do well to consider with sympathy this clamant need of one aspect of the educational progress of the citizens.

THE annual special issue of *The Chemist and Druggist* published on June 28 contains among other historical articles the fourth instalment of Dr. Charles Singer's "Sketches in the History of English Medicine", which deals with the beginnings of the scientific method in the seventeenth century, as exemplified by Harvey, Paré, Sydenham, and the Royal Society, the text being liberally interspersed with contemporary portraits and illustrations of books and instruments. In addition to giving an appreciation of the works of Fabricius of Acquapendente, Harvey, Paré, and Sydenham, as well as an account of the famous medical school at Padua, where Harvey pursued his studies, and of contemporary British pharmacy, of which Thomas Johnson was an eminent representative, Dr. Singer points out that it was in the seventeenth century that the study of tropical medicine in Great

Britain first originated, owing to the discovery of new lands bringing men into contact with new diseases. The earliest English work on this subject was published in 1598 by George Wateson, under the title of "The Cure of Diseases in Remote Regions", to which Hakluyt alludes in his "Voyages" published two years later. In conclusion, Dr. Singer refers to the change in the chemical outlook achieved by Robert Boyle, who not only liberated chemistry from alchemy, but also made chemistry independent of medicine, with which it had hitherto been too closely associated, to the detriment of both.

WE welcome the appearance of a new series of the *Quarterly Journal of Mathematics*, a formerly well-known journal, published by the enterprise of the Clarendon Press. The old *Quarterly Journal* published as a private venture at Cambridge appeared regularly until the War, but only at rare intervals from 1916 until its death on completion of the fiftieth volume in 1926. It is to be hoped that a subject index to the whole fifty volumes will be published in due course. Opportunity has been taken to increase the size of the page in beginning a new series. The style of printing is a great improvement on the former and only possible by the use of fine-quality paper. A strong editorial board is behind the new enterprise, and from the contents of the opening part we foresee that this journal will soon become a recognised medium for the publication of first-class mathematical research. The new journal also incorporates the old-established *Messenger of Mathematics*.

THE University of Brussels, on the proposition of the Faculty of Science, has conferred the degree of doctor *honoris causa* on Sir William J. Pope.

AN Imperial Horticultural Conference, called by the Imperial Bureau of Fruit Production, East Malling Research Station, Kent, under the ægis of the Imperial Agricultural Bureaux, will be held in the Conference Hall of the Royal Society of Arts on Aug. 5-7. The main purpose of the Conference will be to discuss the best methods of approach to horticultural problems and the technique involved. The opening address will be delivered by Sir Robert Greig, chairman of the Imperial Agricultural Bureaux, and papers have been promised, among others, by several workers from the Dominions. The work of the Imperial Bureau of Fruit Production will be described, and groups of papers are to be devoted to horticultural research in the Dominions, applications of pure science to horticultural problems, soil and climate surveys, and fruit storage. The discussions will be open to the public.

THE proposal to establish a college for postgraduate medical study in London has advanced a stage, for the Minister of Health, Mr. Arthur Greenwood, has appointed a provisional organisation committee to proceed with the action necessary to secure the institution of a British Postgraduate Hospital and Medical School. This committee is to consider and report on the action requisite to lead up to the planning and construction of the School, the form of government appropriate for it, and the relation of the School to the London County Council and University of London. The chairman of the committee is the Right Hon. Viscount Chelmsford, and the committee consists of representatives of the Ministry of Health, the London County Council, the University of London, and a number of distinguished medical members, with Mr. M. Heseltine, of the Ministry of Health, as secretary.

THE fifth Pacific Science Congress is to be held in Canada on May 23–June 4, 1932, under the auspices of the National Research Council. Meetings will be held in the cities of Victoria and Vancouver, B.C., and a short tour is planned to follow the congress meetings so that the delegates may see something of the Dominion. The Congress has a twofold purpose, namely, (1) to initiate and promote co-operation in the study of scientific problems relating to the Pacific region, more particularly those affecting the prosperity and well-being of Pacific peoples; (2) to strengthen the bonds of peace among Pacific peoples by promoting a feeling of brotherhood among the scientific workers of all the Pacific countries. The first Pacific Science Congress was held in Honolulu in 1920; the second in Sydney and Melbourne, Australia; the third at Tokio; and the fourth in Batavia and Bandoeng, Java, in 1929. Thus, when the next Congress is convened in Canada, it will be the first of these meetings to be held on the eastern side of the Pacific Ocean.

AN executive committee to organise the fifth Pacific Science Congress, headed by Dr. H. M. Tory, president of the National Research Council of Canada, has been appointed. There are two vice-presidents: President L. S. Klinck, of the University of British Columbia, and Dr. Frank D. Adams, emeritus dean of the Faculty of Graduate Studies, McGill University, Montreal. The treasurer is Mr. S. P. Eagleson, secretary-treasurer of the National Research Council, and Mr. S. J. Cook, also of the National Research Council staff, is general secretary. The office of the Congress is in the National Research Council Building at Ottawa, Canada. There are to be two main divisions of the Congress. The division of biological sciences will be headed by Dr. C. M'Lean Fraser, professor of zoology in the University of British Columbia; the division of physical sciences will be under the chairmanship of Dr. R. W. Brock, dean of the Faculty of Applied Science, University of British Columbia. The Congress will bring to the Dominion and to the study of Pacific problems, in which Canada has a great interest, an international body, including among its members many distinguished men of science from different parts of the world, as well as many others who will influence the development of improved scientific and commercial relations between the Dominion of Canada and the other countries bordering on the Pacific Ocean.

A VALUABLE index to the contents of the forty completed volumes of the *Mémoires de la Société de Physique et d'Histoire Naturelle de Genève*, from 1821 to 1930, has been compiled by John Briquet, and is

published as the final fascicule of Volume 40. It is not a subject index in the ordinary sense, for there is no alphabetical arrangement of the subjects of the papers, but a general alphabetical list of authors is followed by authors' lists grouped according to the various branches of science. In addition, a table shows the year of publication of each part, and a separate list indexes the biographical notices which have appeared, 234 in number.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A deputy chief engineer and an assistant engineering superintendent of works under the Metropolitan Water Board—The Chief Engineer, Metropolitan Water Board, 173 Rosebery Avenue, E.C.1 (July 21). A junior assistant in the pathological departments of the Royal Victoria Infirmary and the University of Durham College of Medicine—The House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne (July 23). An assistant lecturer in agriculture under the Cornwall County Council Education Committee—The Secretary for Education, County Hall, Truro (July 24). A chief assistant under the Scottish Society for Research in Plant-Breeding, for work on virus disease of potatoes—The Secretary, Scottish Society for Research in Plant-Breeding, 8 Eglinton Crescent, Edinburgh (July 29). A professor of education in Rhodes University College—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (July 31). A chief agricultural lecturer and adviser under the Dorset County Council, County Agricultural Committee—The Clerk of the County Council, County Offices, Dorchester (July 31). An assistant lecturer in physics in the University of Birmingham—The Secretary, The University, Birmingham (Aug. 1). A research assistant in the department of mathematics of the Imperial College of Science and Technology—The Registrar, Imperial College of Science and Technology, South Kensington, S.W.7 (Aug. 7). An assistant professor of anatomy in the University of Manitoba—The Dean of the Faculty of Medicine, Medical College, Winnipeg, Canada (Aug. 8). A principal of the Stranmillis Training College, Belfast—The Secretary, Committee for the Training of Teachers, Ministry of Education, Parliament Buildings, Belfast (Aug. 16). Research studentships at the London School of Hygiene and Tropical Medicine in, respectively, entomology and protozoology—The Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1 (Sept. 1). A Samuel Turner research fellow for work on cancer and the pathology of growth, in the University of Liverpool—The Registrar, The University, Liverpool (Sept. 30). A graduate mistress with good qualifications in botany, at Newport, I.W., Secondary School—The Director of Education, County Hall, Newport, I.W.

Our Astronomical Column.

The Planet Saturn. Mr. W. F. Denning writes: "Saturn is now favourably situated in some respects for observation, being visible nearly all night. The rings are now widely open and their northern side is presented to the earth. The apparent diameter of the planet is at present 16·4″. It was in opposition on July 1 at a distance of about 838,500 miles from the earth. Being placed amongst the southerly stars of Sagittarius, its altitude will be very low and only 16° when passing the meridian on July 20 at 10.40 P.M. Telescopic definition will not often favour the observer under the conditions, though in southern latitudes the object will attain a greater height and induce more successful results. The belted aspect of Jupiter's disc is repeated in the case of Saturn, and from their character and the changes affecting them, it seems probable that the atmospheric phenomena are very similar on these large planets. On Saturn, however, they appear less conspicuous and are not so frequently noticed, but this is due in a large measure to the fact of their being fainter and smaller than the features of Jupiter."

Nature of Hagen's Dusky Nebulosities.—Much controversy has raged about the reality of these difficult objects. Father Hagen has been able to collect a considerable body of visual evidence in support of their existence, going back to Sir W. Herschel, and including some well-known observers of the present time. A good many astronomers have felt the weight of the objection that the objects cannot be photographed either on ordinary plates or on red-sensitive ones.

Prof. J. Hartmann makes the suggestion in *Astr. Nach.*, No. 5716, that they may consist of diffused sodium clouds. He notes that, in addition to the well-known stationary lines of calcium, some stars show the *D*-line of sodium as stationary. The *D*-line comes in a region of the spectrum where neither ordinary plates nor red-sensitive ones have much sensitivity; on the other hand, it comes near the maximum of visual sensitivity. The colour of the Hagen clouds has been variously described as brown, yellow, and red. It is difficult to assign an exact colour to very faint objects, so this would not be inconsistent with the wave-length of the *D*-line.

Prof. Hartmann proposes himself to take photographs with a camera of focal ratio $\frac{1}{5}$, using plates as sensitive as possible to this region and a suitable light filter (OG1 on the list 4213 of Schott und Gen.; 2 mm. thick). The exposures will last several hours. He asks that similar photographs should be taken in Europe and North America. He notes that if the light is really monochromatic, it would not be much more difficult to photograph the spectrum of the clouds than the clouds themselves. This would serve to verify his conjecture as to the wave-length.

The Planet Pluto.—Harvard Announcement Card, No. 137, gives the following positions of Pluto deduced by Mr. Ross from plates exposed at Yerkes Observatory.

U.T.	R.A. 1930·0.	N.Decl. 1930·0.	Mag.
1921. Jan. 29·0896	6^h 31^m $21·9^s$	19° 43′ 14″	15
1927. Jan. 6·25	7 4 3·2	21 13 3	15

The positions are in good accord with the recently published orbits.

Prof. P. Stroobant has remeasured the image of Pluto photographed at Uccle 1927, Jan. 27, 21^h 27^m 41^s U.T. using six comparison stars. The new position for 1927·0 is 7^h 1^m $59·965^s$ N. 21° 17′ 44·0″. This should be substituted for the previously printed value 7^h 1^m $59·7^s$ N. 21° 17′ 59·7″, which was inexact. The new value accords well with the calculated orbit.

Research Items.

Tubuai.—An account of Tubuai, one of the Austral Islands, based upon material collected by the Bayard Dominick Expedition, is given by Mr. Robert T. Aitken in *Bull.* 70 of the Bernice P. Bishop Museum of Honolulu. This island lies about 400 miles south of Tahiti and is evidently of volcanic origin. The material culture of the inhabitants is characterised by the taro, coconut, manioc, and banana, and by fish rather than animal foods. The dwellings are Polynesian in design. The islanders fish with the spear and use the outrigger canoe propelled by paddle and sail, but not with the pole. They weave in coconut leaf and lauhala. Their material culture is thus closely related to that of modern Tahiti. The mythology is distinctly Polynesian, containing elements found in New Zealand, Tahiti, and Hawaii. In the social organisation of former days, there were definitely recognised districts, each occupied by a leading man or chief with family, relatives, and followers. There was constant warfare between districts. Powerful leaders from other islands, especially Raivavae, invaded the island and conquered the families of the various districts. The modern language is almost entirely a Tahitian dialect introduced by missions. A few words remembered from pre-mission days indicate that the former dialect approached more nearly to the old Polynesian language. Archæological remains point to a former religious ceremonial life differing from that of Tahiti and similar to that indicated by similar remains in Rurutu and Raivavae. Remains of ancient villages suggest a much larger population in olden times. It is clear from local records that the influence of Raivavae on Tubuai has been very great and that there was frequent interchange of culture and blood.

Peruvian Textiles.—Miss Lila M. O'Neale and Dr. A. L. Kroeber have made an intensive study of the textiles of ancient Peru based upon the collection of the University of California. Some 650 pieces have been examined, and though about 1000 more await investigation, it has been thought expedient to summarise the results to date. These are now published as No. 2, vol. 28 of the *Publications in American Archæology and Ethnology* of the University. These prehistoric textiles are derived from sites on the Peruvian coast from about 300 miles north of Lima to about 250 miles south of that city. In time they cover the whole of Peruvian prehistory from Early Nasca and the primitive fishing period down to Inca. No material from the Highlands was available. The chronological sequence is based primarily on pottery, secondly on building, head deformation, and other cultural traits. The following inferences are drawn: (1) Certain habits persisted, characterising certain regions; (2) changes in period manifest themselves in style rather than in technology and in the preferences given to certain techniques rather than in invention; (3) the fundamental technological control of the art was established at the beginning of the discovered record. In regard to the last it appears, for example, that cotton and wool are used in all periods. The percentage of pieces containing all wool fabrics is as a matter of fact highest in the early period while all cotton fabrics are highest in the latest period. The free use of wool in the early period means that the textile art was then already elaborate and that trade between coast and interior was regular, as the latter alone produced wool. A second point indicating the unity of the art was the loom, which throughout was of the type attached to the weaver's belt. Nearly all the fundamental weaves appear already in Early Nasca. This also holds for the dyes. As regards the decorative designs, these changed to correspond approximately with the designs of the pottery—from typically semi-realistic (pre-Tiahuanacu) to stiffly representative (Tiahuanacu-epigonal) to purely geometric and conventionalised (Late).

North Atlantic Scopelid Fishes. Dr. Å. V. Táning, in his "Synopsis of the Scopelids in the North Atlantic" (*Vidensk. Medd. fra Dansk Naturh. Foren.*, Bd. 86, 1928), surveys those forms which are met with in the Atlantic north of the Equator. The material, which consists of "many tens of thousands of specimens", was collected by the *Dana* and other Danish vessels under the guidance of Prof. Johs. Schmidt. The author has examined for comparison many others from various localities, including some from several European museums. Fifty-seven species or subspecies are noted in the present work, nineteen of which are new. The scopelids, which possess photophores in different positions on the body, are classified chiefly by these organs, and the present survey consists of keys to the species of each genus, giving a clear diagnosis and the distribution in each case.

Californian White Sea Bass. Mr. S. S. Whitehead, in his paper "Analysis of Boat Catches of White Sea Bass (*Cynoscion nobilis*) at San Pedro, California" (Division of Fish and Game of California. *Fish Bulletin* No. 21. Contribution No. 86 from the Californian State Fisheries Laboratory, 1930), summarises the information regarding depletion in the White Sea bass fishery. This fish is important commercially, with an increasing demand. It may reach a length of four to six feet and weigh 50-60 pounds. It was found that the best way of understanding existing conditions was by estimating the catches per month. The averages for both boat catches per month and boat catches per trip were decidedly downward during the period 1918–28. Thus the availability of the White Sea bass has decreased each year, which, unless the fish have changed their habitat, means depletion. The reduction may be due to natural fluctuations over a period of years, or to adverse spawning seasons, or an increase of natural enemies, or to over-fishing. Whatever be the cause, the conclusions are that the White Sea bass fishery needs protection in order to ensure it against extinction in the future.

Halticine Beetles.—Dr. D. Ogloblin of Poltava, Russia, has published in *Eos*, **6**, 1, April 10, 1930, Madrid, an interesting study of thirty-five of Motschulsky's species of Halticine beetles. At one time it was thought that these were lost, but now it is known that they, or at least some of them, exist in the Zoological Museum of the University of Moscow. Entomologists who have to deal with Motschulsky's species suffer from the lack of an exact knowledge of the condition of his types. Dr. Ogloblin's study will remedy this to a certain extent, because, besides many text-figures, his paper is accompanied by an excellent plate of twelve coloured illustrations which were all drawn by the author from the cleaned and remounted types. Dr. Ogloblin is to be congratulated on his work, and it is hoped that he will have more opportunities to publish further studies of Motschulsky's types. The present paper has been edited by Mr. S. Maulik.

Japanese Monograph on *Rhizopus*.—The genus *Rhizopus* was originally separated from *Mucor* in 1820

by Ehrenberg, but the species of this genus are so variable in culture that their systematic study has always presented great difficulties. Yoshihiko Yamamoto has grown as many species as possible in pure culture under different conditions, obtaining species from other workers in the group also; his results are presented in a systematic monograph published in the *Journal of the Faculty of Agriculture*, Hokkaido Imperial University, vol. 28, part 1, March 1930. As a result of this very complete re-examination of the group, fifteen species are accepted, described, and figured.

Cyanogenesis in Plants.—The production of prussic acid in plants is a phenomenon which has considerable economic importance in view of casualties from this cause amongst grazing stock, or even in the case of cyanogenesis in crushed feeding cakes from some sources. The function of cyanogenetic compounds in the normal plants is still completely obscure and a subject of considerable interest, so that the review of the literature of cyanogenesis in plants, by Muriel Elaine Robinson, in *Biological Reviews*, vol. 5, April 1930, will be useful to workers in very varied fields. Prussic acid has now been obtained from plants from about fifty different families, whilst some ten different cyanophoric glucosides have been isolated in crystalline forms; five of these have been prepared synthetically. Seven of these glucosides are derivatives of benzaldehyde cyanhydrin, two others contain ketone groupings. Three of these glucosides, amygdalin, prunasin, and prulaurasin, seem to be restricted to the Rosaceæ, sambunigrin to the Caprifoliaceæ and dhurrin to the Graminaceæ, but linamarin has been found in several families which are widely separated in natural systems of classification. The concentration and seasonal variation of prussic acid in the plant show considerable differences; in general, the concentration seems to be greatest in young growing organs, but there are curious anomalies and so far, the few studies of distribution and seasonal variation of cyanophoric glucosides have thrown no clear light upon their rôle in the plant.

Chloride Manuring for Tobacco. Although it is uncertain whether or not chlorine is an essential plant nutrient, W. W. Garner and others have shown (*Jour. Agric. Res.*, **40**, p. 627) that manuring with chloride has a far-reaching effect on tobacco and may alter the quality of the cured leaf considerably. Field tests were made using chloride and sulphate of potash. Although the plant absorbed potash equally well from both salts, the chlorine ions were taken up much more readily than the sulphate ions, and on light, sandy soils an average increased yield of ten per cent was obtained with applications of 20-30 lb. of chlorine per acre. The soils used were very deficient in magnesium, an element of particular importance for the tobacco crop, and since an application of potassium chloride was found to increase the magnesium content of the plants, it would seem that the stimulating action of the chlorine was probably due to an increase in the availability of the magnesium. Further, the addition of chloride resulted in an increased water content of the leaf, thus enabling the plant to resist desiccation, protecting it against the type of injury known as 'drought spot', a fact which adds materially to its commercial value. On the other hand, an excess of chlorine induces an abnormally high moisture content of the leaf and is therefore liable to injure its combustibility and keeping qualities. In addition, it interferes with normal carbohydrate metabolism, bringing about an accumulation of starch and a thickening of the leaf. These adverse effects may be caused by applications of 40-60 lb. of chlorine per acre and are most likely to occur on light soils, with limited buffering properties. From the economic point of view the chlorine nutrition of tobacco is of the greatest importance, for upon it, either directly or indirectly, the commercial value of the crop may depend.

Cosmic Dust and Meteorites.—It is usual, in considering the cosmic dust, to assume that the velocities of its particles vary in the same way as those of the molecules of a gas (Maxwell's law), but that the masses of the particles are all equal. Levi-Civita, in *Atti della Pontificia Accademia delle Scienze Nuovi Lincei* (March 1930) and *Rendiconti della R. Accademia Nazionale dei Lincei* (April 1930), considers it reasonable to suppose that the masses vary in the same way as the velocities. The results obtained are applied to estimate the effect of the impact of meteorites on a planet moving in its orbit.

Pleochroic Haloes in the Archæan of Uppsala.—The inaugural dissertation of Erik Wiman on "Studies of Some Archæan Rocks in the Neighbourhood of Upsala" (published in the *Bull. Geol. Inst., Upsala*, vol. 23, 1930) contains a series of measurements of pleochroic haloes around zircon and apatite in biotite and hornblende from the Uppsala and Arno granites. In the Uppsala granite haloes with the radius 0·038 mm., corresponding to ThC, are abundantly present. In one case a radius of 0·057 mm. was found. The Arnö granite, however, contains numerous larger haloes with radii 0·055—0·056—0·057—0·060 mm., the value 0·057 being most characteristic of this series. The author adopts this contrast as a means of distinguishing the two granites. Of greater significance is the question of the origin of the larger haloes, for such large radii have not previously been recorded. They are found both in biotite around zircon and in hornblende around apatite, and Wiman thinks that they may point the way to the discovery of a new radioactive substance. They can scarcely be ascribed to the longer α-rays from radium C (Philipp and Donat: *Zeit. f. Physik*, vol. 52, p. 759, 1928), as in that case they should have been previously observed elsewhere.

Fundamental Physical Constants.—During the past year, doubt has arisen as to the accuracy of the standard values of the electronic charge (e) and Planck's constant (h). A welcome contribution to this problem has now been made by Prof. R. A. Millikan himself, in a paper in the second issue of the *Physical Review* for May. Prof. Millikan considers that the only changes which need be made to the numbers which he gave in 1917 are the almost trivial ones which arise from new determinations of the velocity of light, and of the absolute value of the ohm; taking these into account gives, for e, $(4{\cdot}770 \pm 0{\cdot}005) \times 10^{-10}$, for h, $(6{\cdot}547 \pm 0{\cdot}010) \times 10^{-27}$, and for Avogadro's number, $(6{\cdot}064 \pm 0{\cdot}006) \times 10^{23}$. Prof. Millikan also discusses, from the experimental point of view, the most probable value of the spectroscopic fine-structure constant ($1/\alpha$ or $hc/2\pi e^2$), which quantum theory predicts to be 137, and finds that it is highly improbable that this can be a whole number—there is of course no question that its value is *approximately* 137. Using his new values for e and h, and Michelson's redetermination of the velocity of light ($2{\cdot}99796 \times 10^{10}$), Prof. Millikan finds for $1/\alpha$ the value 137·29, which is very close indeed to the quantity $8\pi(8\pi^5/15)^{1/3}$, or 137·348, predicted by Lewis and Adams in 1914 from their theory of ultimate rational units.

Magnetic Properties of Mesomorphic Substances.—Amongst the articles in the 1929 volume of Conférences of the Conservatoire National des Arts et Métiers

(Paris, Hermann et Cie, 1930; 35 francs) is one by Prof. G. Foëx, on the magnetic properties of mesomorphic materials (liquid crystals). These substances, which although fluid are optically anisotropic, are diamagnetic. Those which belong to the nematic class have, however they are formed, a susceptibility definitely less than that of either the related solid or true liquid phase; the smectic class, on the contrary, has a definite lower susceptibility only if formed by cooling the isotropic parent liquid in a magnetic field. The variation with temperature of the susceptibility of a nematic liquid is large, and somewhat similar to that of a ferromagnetic body near its Curie point; Prof. Foëx indeed defines the nematic phase as "a liquid with a molecular field". One curious property of the nematic liquids is that they solidify in a magnetic field to a crystalline mass in which the molecules have one axis orientated. Prof. Foëx's reference to the similarity between nematic liquids and ferromagnetic solids is perhaps of special significance in view of Heisenberg's theory of the latter, which correlates their magnetism with the exchange properties of electrons on quantum theory.

Theory of Magnetism in Iron. If a telephone receiver is connected with the output circuit of an amplifier and an electromagnet is in series with the amplifier, then if a magnet is brought gradually up to the electromagnet and the amplifier is very sensitive, a crackling noise is heard in the telephone. The German physicist Barkhausen, who first noticed the effect about ten years ago, attributed the noises to sudden changes in the magnetisation of the iron. If this is true, it seems to prove that sudden changes in the magnetisation of the iron occur not by single atoms but by much larger groups of atoms. A paper giving the results of research in this subject by R. M. Bozorth is published in the April number of the *Bell Laboratories Record*. He verifies Barkhausen's results and concludes that the ordinary theory of magnetisation must be modified. Instead of accounting for a steady change in magnetic state proceeding atom by atom, the theory must be based on very large groups of atoms making sudden changes simultaneously. For different kinds of magnetic material the sizes of these groups are not radically different, but they seem to vary in size at different points on the magnetisation curve. At saturation on either end of the hysteresis loop, the groups are small, but they increase in size with decreasing magnetisation. A maximum is reached near the steepest part of the curve, where the total magnetisation is about zero. An oscillogram is shown verifying an amplified Barkhausen effect with a 1000 cycle per second timing wave for comparison.

Ionisation of Electrolytes.—Although the hypothesis of the complete ionisation of strong electrolytes is widely accepted, the assumption in some cases is invalid. In the May number of the *Journal of the Chemical Society*, H. E. Blayden and C. W. Davies examine the experimental data for the solubilities and conductivities of thallous chloride. They find that (as in other known cases) the numerical value of the constant in the Debye and Hückel formula is not the theoretical value 0·505. In the present case it is 0·38. The irregularities in the solubility curves found on the assumption of complete ionisation disappear when allowance is made for incomplete ionisation, and the activity coefficient then becomes independent of the nature of the other ions present up to concentrations of decinormal.

Reaction between Hydrogen Sulphide and Silver.—The blackening of silver by exposure to air containing hydrogen sulphide is well known, but the exact nature of the reaction has not been completely elucidated. In the March number of the *Journal of the American Chemical Society*, S. Lilienfeld and C. E. White describe some experiments on the subject. It had previously been shown that the reaction does not occur with dry gas. It was found that phosphorus pentoxide is not suitable for drying hydrogen sulphide, as it oxidises the gas to sulphur dioxide. Silica gel and aluminium oxide prepared by heating the gel at 180° for a week were found to be satisfactory, the latter removing practically every trace of water. It was found that, in presence of air, no hydrogen was evolved in the reaction between silver and hydrogen sulphide, and that no reaction occurred between silver and pure hydrogen sulphide. The presence of oxygen is necessary for the reaction, and attention is directed to the fact that ordinary silver may contain dissolved oxygen. An oxidation of hydrogen sulphide in presence of oxygen, with liberation of sulphur, is suggested.

Hydrogen Chloride in different Solvents.—The original assumption of Arrhenius that the properties of an acid are due to the dissociation of hydrogen ions: $HCl = H^{\cdot} + Cl'$, was modified many years ago by Lapworth and others so as to take account of the undoubted influence of the basic character of the solvent, and Hantzsch had suggested that in aqueous solution the hydrogen ion is really $H_3O^{\cdot}$: $HCl + H_2O = H_3O^{\cdot} + Cl'$. The effect of a solvent in promoting ionisation was also supposed by J. J. Thomson and Nernst to increase with its dielectric constant. In the May number of the *Journal of the Chemical Society*, Wynne-Jones describes some experiments on hydrochloric acid in nitrobenzene, a solvent of high dielectric constant but no marked basic character. If the dissociation is primarily determined by the dielectric constant, nitrobenzene would be a good ionising solvent for hydrochloric acid. This was not found to be the case, the acid behaving as a normal undissociated substance. These results support the view (originally due to H. E. Armstrong and to Lapworth, but attributed in the paper to Brönsted) that the behaviour of an acid is largely determined by the basic character, not by the dielectric constant, of the solvent. In the case of salts, the dielectric constant is the important factor.

Cytochrome as a Biological Oxidation Mechanism.—An interesting paper upon this subject, by Keita Shibata and Hiroshi Tamiya, is published in the *Acta Phytochimica*, vol. 5, No. 1, April 1930. They find that the oxygen-carrying properties of the pigment can function without dependence upon special oxidase or reductase systems that may form part of the respiratory mechanism of the cell. The linkage of cytochrome with oxygen is a ferro-linkage taking up molecular oxygen; naturally, therefore, the presence of potassium cyanide strongly inhibits the oxygen-carrying properties of cytochrome. By various treatments, such as boiling, drying, addition of oxidising agents, etc., the oxygen-carrying properties of cytochrome can be destroyed by a 'denaturing' of the iron to hæmochromogen (Fe'') or hæmatin (Fe''') derivatives. Cytochrome, it is suggested, is very essential to plants living naturally in air, but not to plants which are normally submerged. Owing to the striking capacity cytochrome shows for taking up oxygen, the respiration of cytochrome-containing plasma is, within wide limits, independent of the oxygen tension in the atmosphere surrounding it, whilst, on the other hand, organisms poor in cytochrome show a striking sensitiveness to variations in the oxygen content of the medium. Cytochrome, hæmochromogen, and hæmatin are found to be present in many of the lower animals.

Laboratory Induction Furnaces.

THE Metropolitan-Vickers Electrical Co., Ltd., has developed small induction furnace equipments which are particularly suited for laboratory work. They were originally designed for the Company's own research laboratories, but they are now made commercially. The Imperial Chemical Industries, Ltd., has ordered one which will melt a charge of twenty pounds of metal and is rated at 20 kilowatts. The equipment supplied to the University of Manchester is designed for charges varying from a half to two pounds of metal and is rated at five kilowatts. Two equipments supplied to the University of Sheffield are of rather smaller size, and are used for melting charges of only a few hundred grams of metal *in vacuo*.

The high frequency current required to operate these furnaces is obtained by means of a water-cooled oscillator valve. As the frequency is 500,000, the furnaces can melt very small charges. Whilst a quarter of a ton of steel could be melted with current at a frequency of 500, for small charges much higher frequency is essential. To melt the full charge requires from twenty to thirty minutes, but small charges can be melted in two minutes. So great is the rate at which heat energy is generated that half a pound of steel will evaporate if left in the furnace field for five minutes.

In Fig. 1 a ten-pound ingot of steel is shown being poured from a furnace in the Research Department of the Metropolitan-Vickers Electrical Co., Ltd. The tilting gear shown in the figure is used with the larger furnaces. The three-phase valve rectifier unit is supplied at 10,000 volts by a suitable transformer. It is controlled either by a contactor or by push buttons on the furnace table.

At the back of the furnace table are the tuning condensers and a panel on which is mounted a neon lamp to indicate when the set is oscillating and an ammeter to read the current in the oscillatory circuit. The rectifying valves are protected by a filament voltage relay which prevents the high pressure being applied before the filament voltage has the correct value. A relay is also provided in the water circulation system which trips the contactors of both the main and filament circuits in the event of a failure of the water supply.

Even with charges so small as 20 gm., the weights of the alloys agree to within 0·3 per cent with the weight of the constituent metals. Valuable work on the alloys of zirconium was carried out, using one of these furnaces. It is described in a paper read recently to the Institute of Metals by T. E. Allibone and C. Sykes.

FIG. 1.

Astronomy and Physiology in the "Encyclopædia Britannica".

ASTRONOMY.

THE treatment of a particular department of knowledge in a comprehensive work is less illuminating than might at first be imagined. One's first idea is that one might learn from it the conspicuousness of that department in the whole field of thought. Actually, all that it can reveal on that matter is the editor's opinion. As a text-book, a popular handbook, or a source of inspiration, it is equally unsatisfactory. Disconnected, heterogeneous in diction, style, and direction of approach, abounding in repetitions, it has all the potential faults and few of the virtues of those mediums of expression. The value and significance of the treatment are to be found in the individual article rather than the *ensemble*.

Nevertheless, few additions to popular astronomical literature would be more welcome than a volume containing the collected articles on astronomy in the "Encyclopædia Britannica". It would be infinitely more valuable than current productions of writers with no first-hand knowledge of astronomy who claim a faculty of exposition which they imply has been denied to the working astronomer. Such a volume would be an excellent example of the most neglected branch of scientific literature, the anthology. But if it is to be issued, it should be issued quickly, and the authors should have an opportunity of revising their work.

The task of the departmental editor, though sufficiently exacting, gives little scope for originality. The subject-matter must be distributed under the titles most likely to be looked for, not those of a technical classification. Relative lengths must be assigned to the several articles, and suitable authors must be chosen. The subjects must be treated clearly, concisely, and from the point of view of the general scientific world rather than that of the individual writer. These requirements are in the main excellently fulfilled in "Astronomy", although the last might perhaps have been met a little more strictly. An unsophisticated reader of the articles "Cosmogony" and "Star", for example, would scarcely suspect that there were ideas afloat of the genesis of the solar system and the constitution of the stars other than those so admirably presented there. The initials at the end of an article, for the key to which the reader has to turn elsewhere, are intended as a guarantee of authority rather than a license to express personal predilections, and it would have been better if the universal survey had been maintained throughout.

One excellent innovation is a separate 'article' consisting of a list of the astronomical articles in the

"Encyclopædia". Let no one imagine, however, that astronomy is confined within the boundaries there represented. Besides permeating a few articles, such as "Astrophysics" and "Celestial Mechanics", which might fairly have appeared in the list, the breath of astronomy penetrates more or less deeply the domains of physics, geology, history, philosophy, biography, and indeed almost every realm of thought. He who would gauge the influence of astronomy in human affairs must take the whole encyclopædia for his province.

The specifically astronomical articles are naturally of unequal merit, but they are almost, if not quite, all worthy of the traditions of the "Encyclopædia Britannica"—more than worthy in one respect, for we cannot applaud too heartily their newly-acquired intelligibility to the layman. It has at last been realised that an encyclopædia is a work for the intelligent non-specialist, and with all due respect (and very great respect is due) to some of the classical articles of the past, it must be admitted that they were ugly ducklings in a company where all but the scientific stock were of familiar breed. At the same time, it is pleasing to note that two of the least recondite of former articles have been reproduced: namely, those of Miss Clerke and Sir David Gill on "History of Astronomy" and "Telescope", respectively. These well-known articles could scarcely have been improved upon as a whole, though it seems to us that in two respects they might have been made more suitable for their present purpose. If their date of origin had been given, it would have explained the intangible but very real archaism of the point of view of the writers, which it is impossible altogether to remove by definite alteration of the text; and secondly, amendments might have been made a little more freely without disrespect to the memories of the authors. For example, we feel that it is scarcely fair to repeat that Galileo failed to identify Saturn's rings through lack of "sagacity", and it is unfortunate also that in a historical article the dates of Hipparchus, Ptolemy, Tycho, Kepler, and Galileo should be omitted when those of a host of lesser men are given.

On the other articles, only the most general comments can be made. The definition of the field of astronomy as "the world beyond the earth" seems inconsistent with the inclusion of "Earth" in the list of astronomical articles. The clear description of astronomical photometers in the article, "Photometry" would have been much more easily followed if diagrams had been provided such as those of physical photometers and chronographs. In the matter of technique of exposition, we would direct particular attention to the paragraph "The Demand for Data" in the article, "Astronomy," which comes as near as is humanly possible to our conception of the ideal—a clear statement of a general principle, with vivid examples (*not* illustrations). If every expositor were compelled never to generalise without providing at least one example of the particular, he would not only clear his own mind of much cant, but also would enlighten readers whom otherwise he would only mystify.

Another well-conceived innovation is a list of astronomical societies, though it would have been more dignified generally, and in the case of foreign titles more useful, if abbreviations had not been introduced. The British Astronomical Association appears as the "British Astronomical Society"—a curious blunder which can scarcely have been the unaided work of an astronomer. Indeed, there are other defects which suggest the operation of influences not scientific. It is improbable that the author of the article "Chromosphere" would confuse another astronomer's initials with his own, and the inscriptions under some of the illustrations show a decided laxity of expression when compared with the corresponding articles. The unsigned article "Planet" suffers in a different sense, for its illustrations, which are referred to in various places throughout the "Encyclopædia", are non-existent. Author's proof-corrections appear to have been treated with scant courtesy; to mention one of the least serious examples, the name "Rutherfurd" appears in two articles as "Rutherford," although, in one of them at least, the error was twice corrected in proof.

Such blemishes go beyond the limit of excusable fallibility, but perhaps the most astonishing feat of the publishers—or whoever is responsible—is the 'cutting' of certain articles, without intimation to the authors before publication, because of "congestion in the later letters". It is apparently this procedure that has led, in at least one instance, to the alteration of a true statement into a false one. Cutting admittedly is a necessary process if it is done for an intelligible reason and by a competent agent, but what are we to make of the reason assigned here? If the language is such that the later letters require even a hundred times as much space as the earlier ones, why in the name of all that is rational should they not have it? "The Democracy of Letters" is certainly a familiar phrase, but surely it has never before received such a literal interpretation.

The "Encyclopædia Britannica" remains the leading work of its kind, but it does so in spite, not because, of the arrangements made for its production.

H. D.

PHYSIOLOGY.

IN the selection and presentation of the physiological subjects dealt with in the new edition of this monumental work, the perfection attained proves that the publishers could not have made a happier choice of associate-editor for the physiology section. The enormous development of the science of physiology since the appearance of the thirteenth edition has necessitated the inclusion of matter which is entirely new, and no pains have been spared in bringing the subject right up-to-date. Many of the new articles introduced deal with those branches of the science which have undergone advancement at the hands of Anglo-American workers who have themselves written the articles. As a consequence, two happy results accrue to the reader: he is assured of a much considered and authoritative statement on the subject and of reading of a refreshing nature imbued with the enthusiasm of the research worker.

The contributors, in nearly all cases highly specialised in their respective fields, are to be congratulated on rendering their subjects intelligible to the general reader by expressing themselves in the universal language of science. Remarkably few printers' errors have crept in and none which lead to confusion; the abbreviation error $1\mu\mu$ for $1m\mu$ which appears so commonly in medical writings has unfortunately been adopted for expressing wave-lengths of light in one of the articles.

Articles of a general character, formerly a characteristic feature of the 'Encyclopædia', have been advisedly curtailed, since in a scientific subject they may either suffer from being too vague for the general reader or lack the precision expected by the scientific inquirer. The article on physiology by Prof. J. Barcroft is, however, valuable for its orderly statement of some of the main principles governing the bodily functions, while Prof. J. C. Drummond presents in historical form the development of the comparatively new subject of biochemistry.

The special articles introduce a novel feature of

high educational value and will be greeted with pleasure by workers in the ancillary sciences, since they present a wealth of information presented in a language shorn, so far as accuracy of expression permits, of many of the technicalities inherent to high specialisation. Main headings are, as is usual, arranged in alphabetic order; no better start can be made than by looking up the master organ—the brain—the article on which begins a new volume and is written by the leading authority on the physiology of the nervous system. The account given by Sir Charles Sherrington is so fascinating that the reader is impelled to look up the subsequent articles on the spinal cord and the sympathetic system from the same pen; they may be read with equal delight by the general, the scientific, the psychological, and the physiological inquirer; the evolution of a superman is considered in retrospect under the sub-heading of "Had man had wings".

Prof. Barcroft, in his interesting and inimitable style, outlines the present position of the physiology of the blood, of respiration, and of excretion, and gives the most orderly exposition of the subject of anoxaemia yet published; this should not be missed by any aviator, mountaineer, or medical man. Subjects of interest more limited to physiology and medicine deal with the heart, vascular system, hormones, etc., and these articles give excellent summaries of knowledge to date. Articles of wider general interest, in particular to psychologists and physicists, will be found: hearing by Dr. Wilkinson, vision by Sir Herbert Parsons, light and radiation by Sir Leonard Hill, animal equilibrium by Dr. E. D. Adrian, sleep by Dr. G. Anrep. Not only physiologists and biochemists but also industrial psychologists, athletes, and gymnasts will profit from the article by Prof. A. V. Hill on muscle and muscular exercise. Amongst other articles possessing a wide appeal there may be mentioned hunger and thirst by Dr. W. B. Cannon, tissue culture by Dr. A. Carrel, and insulin by Prof. J. J. R. Macleod: all are distinguished by the stamp of authority and are presented in an interesting manner.

The publishers have not stunted the work in any particular. The text is supplemented by clearly annotated diagrams, and plates are beautifully reproduced on art paper, some in colour. Indeed, all concerned in the production of the physiology section of this gigantic work are deserving of high praise.

Recent Work on Vitamin D.

I.

SINCE the discovery three years ago that ergosterol is converted into vitamin D on exposure to a source of ultra-violet light, to which reference has already been made in these columns (see NATURE, vol. 120, p. 955; Dec. 31, 1927), a considerable amount of work has been carried out on the chemistry of the changes undergone by this compound under various conditions. Although the details of the process of its conversion to vitamin D have attracted most attention, it is only recently that the isolation of the vitamin in a pure state has been reported. Coincident with these investigations, opportunity has been taken to study the effects upon the animal economy of administering very large doses of the vitamin, since even 'impure' preparations of vitamin D are much more potent than its richest natural source, cod-liver oil, and can be given without the complicating effect of accompanying substances, although it may be necessary to distinguish between the actions of vitamin D, other products of the irradiation, and unchanged ergosterol together present in the preparation used.

BIOLOGICAL ASSAY.

In the absence of a simple chemical test for vitamin D or the isolation of the vitamin as a pure chemical compound, recourse must be had in all experiments to the animal test. The animal commonly used is the rat; the diet, one which will in the course of a few weeks produce rickets, and the criterion of cure or healing the change brought about in the calcification at the growing ends of the bones on administration of vitamin D: a modification of this test is to give the vitamin prophylactically instead of curatively. The degree of calcification is estimated chemically, by the ash or calcium content of the bone, histologically, by splitting the end longitudinally and staining with silver nitrate, when the newly deposited calcium salts appear as a line in the metaphyseal cartilage (hence the term 'line test'), or by means of X-ray photographs. It is possible, however, to use other tests: thus under certain conditions vitamin D can be shown to produce an increase in the growth rate, or to bring about a change in the pH of the fæces.

K. M. Soames and J. C. Leigh-Clare (*Biochem. J.*, vol. 22, p. 522; 1928) point out that the common diets used to produce rickets in rats are not only free from vitamin D, but are also deficient in salts, vitamin A, and sometimes protein and vitamin B: they consider that the diet should contain all known requirements except the constituent under test. On a complete synthetic diet free from vitamin D, rickets cannot be produced in the rat, but that calcification is defective is shown by the low ratio of ash to organic residue in the fat-extracted bone, for example 0·9 instead of 1·5 (on the diet plus vitamin D); on a diet low in phosphorus in addition to vitamin D this ratio is 0·5 or less. Vitamin D was given in the form of cod-liver oil and irradiated cotton-seed oil, and besides bringing about normal calcification it also increased the growth rate: under these conditions, therefore, growth can be used as a criterion for the presence of vitamin D. The diets used were of the common synthetic type, vitamin A being given as wheat embryo or hog millet, sources free from vitamin D.

H. N. Green and E. Mellanby (*ibid.*, p. 102) have found that, as in dogs, the degree of rickets developed by rats depends also upon the nature and amount of the cereal in the diet. For testing this point they gave the animals a diet containing 75 per cent of the cereal with caseinogen, sodium chloride, marmite, lemon-juice, and dried cabbage. Oatmeal and whole meal flour are more rachitogenic than barley meal or white flour, with maize meal intermediate. The effect can be antagonised by an adequate supply of vitamin D and also to a great extent by increasing the calcium, though not the phosphorus, intake. The nature of the interfering substance in cereals and the mechanism of its action are not definitely known, but L. Mirvisch (NATURE, vol. 124, p. 410; Sept. 14, 1929) has recently shown that a factor can be extracted from oatmeal with weak hydrochloric acid which lowers the blood calcium of rabbits to the extent of 35 per cent in twenty-four hours.

The usual method of comparing the activity of different samples is to find the amount which will produce a definite degree of healing of rickets or the amount which will just prevent its onset. The drawback of this method is that it presupposes that every animal or a certain number of a group will always respond in precisely the same way to the same dose; but it is notorious that animals vary considerably

among themselves, even when all conditions of diet, maintenance, etc., are kept as constant as possible and an inbred stock is employed. It is for this reason that standards for biological remedies have been set up, the potency of the unknown preparation being determined in terms of this standard; in this way, variations due to the animals are to a large extent eliminated, since the response of a group to the standard and to the unknown varies usually in the same direction; comparable results can therefore be obtained with the same preparations at different times and in different laboratories. K. H. Coward (*Quart. J. Pharmacy*, vol. 1, p. 27; 1928) has adopted as standard of reference a preparation of irradiated ergosterol, of which 0·0001 mgm. is defined as containing one antirachitic or vitamin D unit; the comparison is made by means of the 'line' test and the test doses are fed for 10 days after 3-4 weeks on a preparatory rachitogenic diet. In her animals, this dose of the standard preparation brings about complete healing, whilst $\frac{1}{20}$ of it may produce early definite signs of calcification in the metaphysis.

The sensitiveness of the test is also indicated by some results obtained by Fosbinder, Daniels, and Steenbock, which were confirmed by Coward (see *Biochem. J.*, vol. 22, p. 1221; 1928). The former authors found that $3{\cdot}2 \times 10^{13}$ molecules of vitamin D were formed when 'impure cholesterol' was exposed to radiation of 2650 A. for 22·5 sec., by calculation from the energy absorbed; this corresponds to 2×10^{-8} gm. vitamin D on the assumption that the molecular weight of the vitamin approximates to that of cholesterol. This amount fed over ten days produced a positive 'line' test. Coward found that 2×10^{-7} gm. of a sample of irradiated ergosterol fed over ten days also gave a positive test: if it may be assumed that only 10 per cent of the preparation consisted of vitamin D, Coward's result agrees with that of Steenbock.

E. Poulsson and H. Lövenskiold (*Biochem. J.*, vol. 22, p. 135; 1928) point out that methods using chemical or histological criteria do not take account of the degree of rickets present when the test doses are first administered, except in so far as certain animals of the litter may be killed and examined at the end of the preparatory period, but this procedure does not guarantee that the others are suffering from the same degree of rickets, since variation is found even amongst the animals of the same litter. By taking X-ray photographs of living rats, however, it is possible to follow the healing or not of rickets when a dose of the substance under test is fed, the base line, so to say, for each animal being its own condition at the end of the preparatory period. In practice, the latter lasts twenty-five days and the test doses are given for six days. The unit is defined as that amount which will bring about a marked degree of healing of rickets.

H. Jephcott and A. L. Bacharach (*ibid.*, vol. 20, p. 1351; 1926; vol. 22, p. 60; 1928) found that on Zucker's 'patent flour' diet the *p*H of the fæces of rats becomes alkaline and that with the administration of a source of vitamin D the reaction shifts back to the acid side of neutrality again: the estimations must be made by the electrometric method. After 10-21 days on the diet, the fæcal *p*H is 7·3 or higher: within a few days of giving an adequate amount of vitamin D the *p*H has fallen to 6·7. The amount necessary to bring about this change is taken to be 10 *p*H units.

A number of authors have examined the *p*H of the intestinal contents or fæces under various conditions and in different animals and have not always succeeded in demonstrating the alkaline change in rickets or the acid change with its healing. Thus T. Redman (*ibid.*, vol. 22, p. 15; 1928; vol. 23, p. 256; 1929) using the quinhydrone electrode, found no relationship between the *p*H of the fæces and the condition of rickets in children, although there was a tendency for the *p*H (and calcium output) to fall with treatment. Working with S. G. Willimott and F. Wokes (*ibid.*, vol. 21, p. 589; 1927), however, it was found that the changes could be demonstrated in rats maintained on rachitogenic diets. Bacharach and Jephcott, in a recent paper, reply to certain criticisms of their method, and point out that it is a means of measuring vitamin D, and that the changes in *p*H do not indicate either the development or cure of rickets (*J. Biol. Chem.*, vol. 82, p. 751; 1929). In performing the test, it is essential to give only vitamin D (in solution in an oil), and not a preparation which may alter the ratio of the constituents of the diet, more especially its salt content. The test is specific for the vitamin only under well-defined conditions: its advantage is that the preparatory and test periods are of shorter duration than is necessary when the degree of calcification is taken as the criterion.

Congress of Experimental Phonetics.

THE first Congress of the International Society of Experimental Phonetics was held at Bonn on June 10-14. It was specially characterised by the variety of the addresses and demonstrations from all parts of the science of speech.

Particularly striking was the demonstration of a Röntgen speech film by Dr. Gutzmann, Berlin, in which the movements of the larynx, hyoid bone, and tongue appeared with great clearness. W. Lenk, Vienna, demonstrated a speech film apparatus suitable for laboratory use. Dr. Moses, Cologne, presented the results of the application of the science of experimental phonetics to character. Prof. Scripture, Vienna, presented his theory of the nature of the vowels. The vowels were also discussed by Dr. Van der Elst, Utrecht, and Dr. J. Schmidt, Bonn. Miss Janvrin, London, presented the results of an experimental analysis of a record of verse spoken by John Galsworthy himself.

The pathology of speech was treated in three addresses, namely: Prof. M. Isserlin, Munich, problems of the pathological physiology of speech (aphasia); Dr. Berger, Münster, phonetic investigations of the genuine and simulated results of the Lombard test; Dr. L. Kaiser, Amsterdam, registration of pathologically altered voices.

Linguistic phonetics was represented by the following: Prof. E. Blancquaert, Ghent, comparative investigations of Nederland dialects; Dr. L. Hegedüs, Gödöllö, experimental phonetic investigations on the melody of Hungarian; Prof. J. Feltes, Luxemburg, concerning the characteristic phenomena of assimilation in Luxemburg speech; Dr. E. W. Peters, Tartu, experimental investigations of the Esthonian language.

In an address entitled "What is Experimental Phonetics?" Prof. Scripture showed that experimental phonetics is approaching the ideal established by the exact methods of chemistry, psychology, and biology.

The exhibition included various oscillographs, film apparatus, graphic registration apparatus, harmonic analysers, and numerous other devices.

The Congress was attended by more than a hundred

people. An account of the proceedings will be published as a separate volume at the price of 10 shillings.

At a meeting of the Council, the secretarial bureau was definitely located at 73 Welbeck Street, London, W.1, and arrangements were made to send the following publications free of charge to the members: *Zeitschrift für Experimentalphonetik*, *Bulletin of the International Society of Experimental Phonetics*, *Bulletin de la Société Internationale de Phonétique Expérimentale* and *Sprachneurologische Mitteilungen*. The membership fee was fixed at 10 shillings per annum.

Prof. Hugo Pipping, Helsingfors, has been made an honorary member of the Society.

University and Educational Intelligence.

A VACANCY having arisen for the Busk studentship in aeronautics for 1930–31, the trustees hope to make an appointment shortly. The studentship is of the value of about £150, tenable for one year from Oct. 1, and is open to any British subject of British descent who has not attained the age of twenty-five years on Oct. 1 next. The object of the studentship is to enable the holder to engage in research or preparation for research in aeronautics, and specially in those subjects, such as stability problems, meteorological questions bearing on flight, or the investigation of gusts, treated either experimentally or mathematically, in which Edward Busk was specially interested. Forms of application, to be returned not later than July 26, can be obtained from Prof. B. Melvill Jones, Engineering Laboratory, Cambridge.

THE Air Ministry announces that five hundred aircraft apprentices, between the ages of fifteen and seventeen years, are required by the Royal Air Force for entry into the Schools of Technical Training at Halton, Bucks, and at Cranwell, near Sleaford, Lincs. They will be enlisted as the result of an open competition and of a limited competition which will be held shortly by the Civil Service Commissioners and the Air Ministry respectively. Boys in possession of an approved first school certificate may be admitted without other educational examinations. The scheme offers a good opportunity to well-educated boys of obtaining a three-years' apprentice course of a high standard and of following an interesting technical career. Particulars can be obtained upon application to the Royal Air Force (Aircraft Apprentices' Dept.), Gwydyr House, Whitehall, London, S.W.1. The sons of officers, warrant officers, and senior N.C.O.'s of the three services will receive special consideration.

THE Teachers Registration Council, which came into existence in 1912 and now functions as the executive of the Royal Society of Teachers, views with concern the slowing down during the past five years in the flow of applications for membership. In 1914 there were 5150 applications. During the three succeeding periods of five years the applications numbered, respectively, 25,780, 44,470, and 4680. In a communication addressed to members in May last, Lord Gorell, president of the Society, observes that up to the present the Council's work has not received that measure of official recognition which is necessary to make a register of teachers effectual as a means of protecting the public from unqualified practitioners, and "the time has come when a serious effort should be made to induce the Board of Education and local authorities to attach due weight to registration in the appointment of teachers to posts of responsibility". It is the Council's aim to secure in the first instance that no one save registered teachers shall exercise professional supervision over the work of other teachers, but the Board of Education can scarcely be expected to adopt this policy while a large proportion of those qualified for registration remain outside the Society. The president therefore suggests that every member should secure at least one recruit during the next three months. The registration fee is to be increased to £3 on July 1, 1931. It appears that the revenue of the Council from all sources from 1912 to 1929 was £123,293 and the expenditure £98,566. Twenty-one cases of registered teachers accused of conduct likely to bring discredit upon the teaching profession have been investigated and nineteen names have been removed from the register.

ON June 7 the inauguration of the new president, Dr. Karl Taylor Compton, of the Massachusetts Institute of Technology, took place in the presence of a large gathering of delegates from educational institutions in the United States and abroad. Sir William Bragg represented the Royal Institution. Addresses were delivered by the retiring president, Dr. S. W. Stratton, who now becomes chairman of the corporation of the Institute, and by the new president, Dr. Compton. At a subsequent dinner, at which many of the *alumni* of the Institute were present, Mr. Gerard Swope, president of the General Electric Co., and a graduate of the Institute, announced the formation of a fund for the purpose of helping needy students of promise to obtain their education at the Institute. In his speech he said, *inter alia*, that they were embarking upon a new plan of organisation in dividing the administration between a chairman and president. For some time the question of increased pay for the teaching staff has been under consideration and also further facilities for research, and it has been decided to increase the tuition fees next September from 400 to 500 dollars, but as the cost of educating a student is between 700 and 800 dollars a year this would mean that, unless more money was forthcoming, the intention of raising stipends could not materialise. He announced that, though only a few had been approached, the fund has already exceeded the sum of 4,200,000 dollars, which will be paid over a ten-year period. The instalment payments will keep it going until the loans made to students have been repaid after graduation. The subscriptions are in the form of donations, and include 500,000 dollars from Mr. George Eastman, who has previously been a generous benefactor, a like sum from C. Hayden, A. P. Sloan, and E. S. Webster, and also large sums from others, among whom was Mr. Swope. Among the announcements made by the new president was the proposal to construct a new chemical and physical laboratory to provide for the increased numbers taking these subjects.

Historic Natural Events.

July 20, 1723. Storm.—The "Journal of Étienne Azambourg", a farmer of Enfournet, Dépt. du Cher, records a "flood of water from a storm and frightful thunder" which ravaged the whole district about 2 to 3 P.M. Vines were stripped and uprooted, and the wind and rain destroyed the grapes, causing enormous loss.

July 20, 1921. Whirlwind in Ceylon.—About 7.30 A.M. a tornado passed directly across the school at Veyangoda, Ceylon, which collapsed with 70 or 80 boys in it. One was killed and another seriously injured. Neighbouring houses were also damaged. The whole track was only about three miles long, and very narrow.

July 22, 1801. Hurricane at the Bahamas.—A terrible hurricane devastated the Bahamas. At Nassau, although the ships in the harbour had their masts struck and anchors down, they all broke loose and were driven on shore, and of the ships at sea, apart from those which were sunk, 120 were counted at one time lying as wrecks on the coast. The sea broke through the sand hills south of Fort Montague, flooding the land, and enormous damage was done.

July 22, 1907. Thunderstorms over the British Isles.—In North London a certain amount of damage was done by heavy rain, but in South Wales and the west of Ireland the storms appear to have been really exceptional. In Wales heavy rain and hail fell on the Black Mountains; the hailstones varied in size from a walnut to a hen's egg. On the Llanthony Road they were five feet deep, and near Tredrenow they completely blocked the river, turning it from its course across the road and the adjoining land, so that trout and other fish were left on the fields. In south-east Clare, Ireland, there were extensive floods, which washed away roads, carried off sheep and pigs, and destroyed whole fields of crops. Five large stone bridges were carried away, and in one place a dead ass was left in a tree, fifteen feet above the ground, by the flood.

July 22, 1925. Thunderstorm over England.—Violent thunderstorms occurred at many places, including London, on the night of July 22–23. Hail occurred in places, especially in eastern London, where the hailstones were reported to be as large as a man's fist. Very many windows were broken, and corrugated iron was cut through by the hail. The amounts of rain and hail were very heavy.

July 24, 1818. Hailstorm in Orkneys.—A great storm of hail traversed a path 20 miles long and 1½ miles broad, at the rate of 4 miles an hour. At each place it lasted 9 minutes, during which time 9 inches of hail fell. During the passage of the storm the barometer fell 1·15 in.

July 25, 1743. Great Heat in Pekin.—Between July 14 and 25 Pekin suffered from glowing heat. Temperature rose to 121° F. and 11,000 men suffered from sunstroke.

July 25, 1910. Eruption of Usu-san (Japan).—An interesting, though by no means violent, eruption began in the small volcano of Usu-san in Hokkaido, the northern island of Japan. It was preceded by frequent earthquakes, 638 being recorded between July 22 and 25, in consequence of which all the inhabitants were removed from the district and there was no loss of life. The eruption consisted of small outbursts of ashes, without any lava, from a number of craterlets along a curved band north of the volcano. On Aug. 6 it was found that the land on the northern flank of the volcano was rising, and a portion 3000 yards long and 625 yards wide was uplifted until it became a new mountain. By the beginning of November, the elevation amounted to 510 feet, but, about this time, a reverse movement set in, and in April 1911 the height was 120 feet less than in the previous November.

July 26, 1798. Atmospheric Refraction.—At about 5 P.M. the coast of France became clearly visible from the shore at Hastings, Winchelsea, and neighbouring parts of the south coast of England, and appeared to be only a few miles away, although the distance is actually 40 to 50 miles. The various features of the French coast were easily recognised, and with a telescope even the buildings on shore. This phenomenon continued fully developed until after 8 P.M., when it gradually faded away.

Societies and Academies.

LONDON.

Physical Society, June 26.—**M. C. Johnson**: The effect of photosensitised mercury vapour on the walls of silica vacuum tubes. An investigation is made into some phenomena occurring at the gas-solid interface in the well-known experiments in which mercury atoms absorb energy from the radiation λ 2537 and then transfer that energy to other gas molecules at collision. It is shown that a combination of both condensation and liberation of gas at the surface of the apparatus must be taken into account, if the effects of irradiation of a gas mixture are to be traced by any of the usual methods of observing pressure changes.—**H. R. Nettleton** and **F. H. Llewellyn**: A sensitive rotating-coil magnetometer. This paper describes a sensitive rotating-coil magnetometer in which the flux due to the earth's field or to a magnet is neutralised by that due to a current passing through a fixed concentric compensating coil which forms with the rotating coil a variable mutual inductance. It shows how the first-order correcting term due to the length of the magnet may be made to vanish if the angle of contact be suitably chosen, and that the second-order correction may be eliminated by a correct choice of the dimensions of the coil.—**L. Hartshorn**: The frequency errors of rectifier instruments of the copper oxide type for alternating current measurement. Alternating current milliammeters containing copper oxide rectifiers possess frequency errors of an unusual type. The errors are almost independent of the instrument reading, and thus the percentage errors are inversely proportional to the current to be measured, and may be very large for small currents. It is shown that the errors are due to the capacities of the rectifiers, which, in milliammeters, are of the order $0{\cdot}09\mu F$.—**D. S. Perfect**: A method of eliminating the effects of magnetic disturbance in highly sensitive galvanometers. The paper describes a method of making correction for the chaotic fluctuations, of magnetic origin, to which the zero of a highly sensitive moving-magnet galvanometer is susceptible. The method consists in the employment of a second galvanometer with properties adjusted as nearly as possible to identity with, and placed as close as possible to, the first. No current is passed through the second galvanometer, which acts in this respect as a dummy the sole function of which is to record the zero changes.—**M. C. Marsh**: The thermal insulating properties of fabrics. One of the chief properties of a fabric is its thermal insulation, which prevents excessive heat-loss from the body. The paper gives a critical review of methods used in the past for measuring the thermal insulating properties. These are discussed with the view of making a new apparatus for the study of the subject.—**Wm. Band**: Classical quantum theory and X-ray excitation by canal-rays and alpha-particles. This paper shows, by application of the classical quantum theory and simple equations of energy, that it is not possible for canal-rays of normal experimental energy to remove K-electrons from the atoms of a metal target either by capture or by simple removal into free space.—**A. T. Mackay**: Diffusion from an infinite plane sheet subject to a surface condition; with a method of application to experimental data. The solution of the partial-differential diffusion equation for the infinite plane sheet is found by operational methods subject to a surface condition analogous to Newton's law of cooling.—**S. Tolansky**: Intensity modifications in the spectrum of mercury. The modifications produced in the spectrum of mercury

by the use of high-frequency discharges have been studied from λ7000 to λ2400, and the lines λ4916 and λ5461 have been examined with high resolving power for fine structure.

DUBLIN.

Royal Dublin Society, May 27.—**W. R. G. Atkins** and **E. Wyllie Fenton**: The distribution of pasture plants in relation to soil acidity and other factors. *Cynosurus cristatus*, *Lolium perenne*, and *Dactylis glomerata* are unimportant in soils of greater acidity than *p*H 5·5. Wild white clover is the main leguminous constituent of acid pastures, not more acid than *p*H 5, above which acidity *Ulex spp.* only occur. In dry soil at *p*H 8 in Cornwall *Medicago sativa* persisted well for six years, also *M. lupulina*. When allowed to roam freely, sheep and cows were found to graze only slightly on pastures with soil acidity exceeding *p*H 5. Extraction with dilute potassium chloride leads to large errors in determining soil *p*H values. **W. R. G. Atkins** and Miss **F. A. Stanbury.** Photo-electric measurements of illumination in relation to plant distribution. Pt. 3. Certain spruce, larch, oak, and holm oak woods. Simultaneous measurements were made of the illumination in and outside the woods, the ratio of total vertical to diffuse vertical illumination being also determined. From these the daylight factors were calculated. Under *Ilex aquifolium* the daylight factor was only 0·6 per cent and nothing grew. In the spruce and holm oak woods values such as 1-3 per cent were common, with 3-16 per cent in the larch wood and 2-11 in the oak wood. **C. P. Martin**: The raised beaches of the east coast of Ireland. The pre-glacial raised beach described by Wright and Maufe on the south coast of Ireland extends round on to the east coast and as far north as Co. Down. The Neolithic raised beach extends as far south as Co. Wexford. The dating of the Neolithic raised beach by human implements found in association with it is unreliable.

June 26. Report of the Irish Radium Committee for the year 1929. 14,730 mc. of radon were issued for therapeutic purposes. Reports from medical users give particulars of treatment of some 370 cases. **M. Grimes**, Miss **V. C. E. Kennelly**, and **H. A. Cummins**: A study of fungi found in butter.—Miss **V. C. E. Kennelly** and **M. Grimes**: *Paecilomyces hibernicum*; new species.

PARIS.

Academy of Sciences, May 19.—**M. D'Ocagne**: Pascal's arithmetical machine. This old machine has been put into working order, by simple replacement of worn or corroded parts. It is noteworthy that in Dr. Roth's machine (1841), one of the improvements claimed as new was realised in Pascal's machine.—**V. Grignard** and **J. Dœuvre**: The transformation of *l*-isopulegol into *d*-citronnellal. The isopulegol was passed over 50 cm. of glass wool, at 500° C., under a pressure of 25 mm. The β form of citronnellal was obtained with a good yield.—**Jean Baptiste Senderens**: The catalytic dehydration, in the gas phase, of the fatty alcohols in the presence of alkaline bisulphates. Fused sodium bisulphate acts on *n*-propyl alcohol vapour at 125°-140° C., giving water and propylene. Isopropyl alcohol reacts in the same way at 105°-110° C. The results obtained with methyl, ethyl, and isobutyl alcohols are also described.—**Jean Effront**: The chemical nature of amylose. Amylose is not a homogeneous product. At the temperature of the formation of starch paste, the starch undergoes a profound depolymerisation. During the ageing of starch solution, a molecular polymerisation is produced, giving rise to different hexosanes.—**W. Vernadsky**: Natural waters rich in radium. An account of the various amounts of radium found in various natural waters. The highest proportion found hitherto is in the subterranean waters accompanying a petroleum deposit at Novyj Groznyj in the Caucasus, amounting to more than 1×10^{-8} Ra per cent.—**Marcel Vasseur**: The equations of Laplace.—**A. Lokchine**: The influence of an elliptical hole in a beam which undergoes bending.—**G. Maneff**: The electromagnetic energy in the field of gravitation.—**Henry Favre**: An optical method for determining the internal tensions in solids of three dimensions.—**A. Bogros**: The structure of the lithium line 6708.—Mlle. **C. Chamie** and **Marcel Guillot**: The centrifugation of hydrochloric acid solutions of polonium. Photographic impressions of groupings of polonium atoms can be obtained with sufficiently active solutions of normal hydrochloric acid strength; and these give no precipitate on centrifugation. It has still to be proved whether these groups pre-exist in the solution or whether they are formed in contact with the surface on which they are photographed.—**E. Herzog** and **G. Chaudron**: Study of the mechanism of the corrosion of the duralmins by sea water. Under oxygen pressures up to 90 atmospheres the losses of weight of the alloys in salt solution are proportional to the pressure. The corrosion is very rapid and the corrosion requiring five or six months at the ordinary pressure can be obtained in 24 hours under high pressures of oxygen.—**P. Cordier**: A new diaryl-alkyloxysuccinic anhydride.—**Fr. de Rudder** and **H. Biedermann**: The pyrogenation of methane. The effects of the variables temperature (900 C. to 1500 C.), pressure (20 mm. to 760 m.) and time of contact with hot tube (15 sec. to 0·01 sec.) have been studied independently. The temperature appears to be the most important factor. The presence of catalysts does not affect the reaction.—Mme. **Ramart-Lucas**, Mlle. **Biquard** and **Grunfeldt**: The configuration of molecules in space. The absorption in the ultra-violet of the groups CH_3 and CH_2. The saturated normal fatty acids, $C_nH_{2n+1}CO_2H$, possess for ultra-violet light an absorption coefficient which is practically independent of n. In the region 2500–2200 A. the groups CH_3 and CH_2 cannot be regarded as chromophores.—**A. Wahl** and **Jonica**: The influence of substitutions on the colour shades of the sulphonated derivatives of stilbene.—**A. Duparque**: The causes of the differentiation of coals.—**Jean Lombard**: The Cretaceous of the Gabon coast line.—**Marcel Mascré** and **Maurice Herbain**: New experiments on the precipitation of nitrogenous substances in serums in the presence of formaldehyde.—**Henri Jean Frossard**: Arterial pressure and its measurement by the pulse method.

VIENNA.

Academy of Sciences, Mar. 20.—**J. Pollak**, **M. Heimberg-Kraus**, **E. Katscher**, and **O. Lustig**: The action of chloro-sulphonic acids on cyclic hydrocarbons. Sulpho-chlorides and other products were obtained from benzol, toluol, xylol, di-phenyl, and naphthalene.—**M. Holly**: Synopsis of the fresh-water fishes of the Cameroon.—**M. Beier**: Zoological expedition to the Ionian Isles and the Peloponnesus, 9th part, Crustacea. Amphipoda by **S. Karaman** and Decapoda by **O. Pesta**.—**A. Tornquist**: Perimagmatic types of east alpine ore deposits.—**B. Knaster**: One-dimensional non-comparable continua.—**K. Menger**: On laminable tri-graphs and powers of non-laminable graphs.—**K. Menger** and **G. Nöbeling**: The *n*-leg theorem in locally connected continua.—**G. Nöbeling**: A refinement of the *n*-leg theorem.—**G. Nöbeling**: *N*-dimensional universal spaces (2).

Rationalisation of Research.

FOR the plain man and, even more, for the scientific worker and many Empire industries, it is extremely desirable that some authoritative pronouncement should be issued detailing the *raison d'être* and the lines of work of the several institutions and research centres in Great Britain which are endowed or supported by Government grants. Even the scientific worker of the present day may be pardoned if he finds it difficult, amongst an apparently bewildering number of institutes and research centres, to pick out the one at which he can obtain the most authoritative information upon the work in which he is interested; for the industrial inquirer the position is even more difficult; whilst the farmer is often hopelessly lost, when all he requires to know is the reason why a portion of his crop is failing. The farmer wants the answer at once: he has lost all interest (having lost that part of his crop) six months later, when an answer may arrive, after he has been sent from pillar to post.

The last few years have witnessed the advent of the Imperial Economic Committee, the Empire Marketing Board, the Government research laboratories connected with the Army, Navy, and Air Force, the several agricultural research and experimental stations now in existence in the country, increased by special lines of research undertaken at the Universities of Cambridge, Edinburgh, and so forth; the Forest Products Research Laboratory at Princes Risborough, the Imperial Forestry Institute at Oxford, etc. Among these centres are some which are not directly endowed with Government grants. The rest, under the supervision of the first or second body above mentioned, are, it is believed, influenced or stimulated to carry on work and to build up collections; the latter being either on a local or home standard, or on the far larger and more costly Empire one—these collections requiring buildings for housing and staff to look after them. In other words, the pendulum has swung with a vengeance and the pre-War apathy appears now to be leading the country into unnecessary (because unorganised) duplication of centres, buildings, exhibits, and so forth.

Before the War the scientific inquirer had a few well-known centres to which he resorted for information. To take two examples: Kew, with

its unrivalled collections of plants, timbers, and so forth—a collection of such excellence that it would take years to reproduce anything similar; and anything of less value would still necessitate the inquirer or student, having access to it, visiting Kew to complete his studies and investigations. Another centre designed for answering economic inquiries and for housing collections of economic products was the Imperial Institute—starved of funds for many years, it is true, but still inaugurated with a definite economic aim.

What is the position of the Imperial Institute to-day? From the annual report for 1929, written by the director, Lieut.-General Sir William Furse, and recently issued, it would not be easy for any but the highly technical expert to frame an answer: and the ordinary scientific worker and specialist inquirer would perhaps find it extremely difficult. For the report furnishes plentiful evidence that the Institute is engaged upon a wide series of economic inquiries and investigations involving elaborate research work. How is this co-ordinated with other research centres receiving Government grants?

It may be assumed that both the home government and all the dominion governments have a full belief in the importance and value of the work of the Institute. The high commissioners of all the latter are members of the board of governors; the trustees include several cabinet ministers; government departments are represented on its managing committee, as also are well-known men of science and others representing commercial interests. The Institute consists of several departments: for example, plant and animal products department, of which Sir David Prain is chairman of the advisory council; mineral resources department, of which Sir Richard Redmayne is chairman of the advisory council; Ceylon rubber research scheme; sericulture research. Investigations into vegetable fibres, timbers, crops for Kenya Colony, improvement of Burma rice, and many other important investigations are dealt with in the annual report.

The work carried out by the Institute with the approbation of the Government, and more important still, the Treasury, is of the greatest value, and its inception, although for so long cold-shouldered, may be regarded as an inspiration. The Institute is a centre to which all can resort, the serious investigator and the citizen who wishes to understand something of the great Empire of which he is privileged to be a member. The educational value of the Institute has been increased by the addition of a cinema, and the provisions made for the visits of parties of school children; and no finer educational centre for the youth of Great Britain could be found.

This being the present position, has not the time arrived when it becomes the duty of Government, in the interest both of the taxpayer and to prevent the wasteful and unnecessary duplication of work, buildings, and exhibits, to have a list drawn up of all institutions existing in Great Britain which are maintained either wholly or in part from Government funds or grants? This list should give details as to the exact nature of the work carried out by each; the reason or necessity for acceding to the demands for extra buildings to accommodate exhibits, perhaps already existing in other institutions in the country, extra staff, and so forth. With such a list available it might be found that Government was making grants to institutions for the purpose of carrying out work which was already being undertaken efficiently by existing institutions.

There would appear to be little doubt that such an inquiry is needed to avoid further waste of money both on the part of the home government and on those of dominions and colonial governments. The latter, as is well known, have received many calls of recent years to collect and forward specimens of a varying nature, many of these requirements being duplications of previous ones already furnished to other institutions. Further, in certain cases these governments are being invited to make grants of money to specialised educational or research centres in Great Britain. It would seem a duty imposed on the home government to be in a position to place before them a list of all centres engaged in the particular line of education or research.

It is known that duplication of the kind to which attention is here directed does exist. It is also known that the average scientific investigator and the commercial man, unless in close touch with the centre of affairs, is bewildered by the apparent multiplicity of institutes and research centres some of which are apparently undertaking work, or competing with each other (in some instances unknowingly), in the same field. A list of Government aided research institutions such as we have suggested above would largely prevent this duplication of effort and, what is perhaps indirectly even more important, would lead to wider use and fuller appreciation of the services which they can render to both science and industry.

The Compleat Anthropologist.

Notes and Queries on Anthropology. Fifth edition. Edited for the British Association for the Advancement of Science by a Committee of Section H. Pp. xvi+404. (London: Royal Anthropological Institute, 1929.) 6s.

THE first edition of this indispensable guide to field anthropology was published in 1874 "to promote accurate anthropological observation on the part of travellers, and to enable those who are not anthropologists themselves to supply the information which is wanted for the scientific study of anthropology at home". This was a counsel of perfection; but there were no schools of anthropology in Britain then, and very few elsewhere, and the risks of mistakes of observation were not fully appreciated, as a glance at the first edition shows. Successive editions, and especially the fourth, in 1912, substituted for many of the original lists of direct questions a short outline of the kind of information already acquired, with hints as to topics most worth elaborating. It was realised that the whole subject of physical anthropology was best left to medically trained observers, and psychology to psychologists; and the general advance in method was held to necessitate careful definition of many of the commoner phrases and terms, especially for those complex social systems which were now attracting the special attention of home-workers, and eliciting some valuable observations in the field.

In the present fifth edition, the 'notes' have still further been expanded at the expense of the 'queries', and the whole work has grown almost beyond pocket-book size: the fourth edition runs to 288 pages, the fifth to 404. The increase is mainly in the section for "sociology", which has been more than doubled in length; "marriage and sexual relations" alone being allowed seventeen pages instead of three, and the "regulation of public life" twenty instead of about six differently grouped. The economic sections also have been very much remodelled. All this reflects current tendencies in "anthropology at home", and the realisation that customs are much more difficult to collect than war-clubs. The numerous definitions which have been thought necessary are very carefully done; but some of them may have to be undone before this edition is exhausted. Too often one has seen the definition of an anthropological word in an earlier edition of "Notes and Queries" used as a starting-point for a systematic restatement of a whole problem. The new section on "Law and Justice" is admirably planned, and should be of the greatest use to administrators of native communities: it puts the old sections on "property", "land tenure", and "inheritance" into a coherent setting, and it is a question whether "slavery" should not be grouped with them. The old section on "morals" seems to have vanished; but "psychology" has come back, with sections on "primitive mentality" and on "dreams". It is always difficult to draw the line between pure and applied science, and usually the compilers of this edition have been discreet; but there is a lapse on p. 171 where, in a matter of child-psychology, "this point has been brought forward not so much for its anthropological as for its administrative value": followed by remarks about depopulation, its causes, and a "better position to deal with the problem", which are not anthropology at all.

When the fourth edition was published, the study of magic and of religion was in a chaotic and transitional phase, which gave popularity to the comfortable term 'magico-religious' to describe this whole group of facts. This usage apparently persists but it is qualified by quite wholesome attempts to define both 'religion' and 'magic' before going on to discuss what may turn out to be either; and the suggestions supplementary to the general requirement of "sympathy and gentlemanly behaviour" in an anthropologist are excellent. It is a much-needed caution (pp. 177-178) that while very few occurrences in the life of uncivilised peoples are without their religious aspect and ingredient, quite as few religious beliefs or observances are unrelated to some occurrence or need in daily life: "pure religion and undefiled", in the philosophical and personal sense, is one of the more ethereal distillates of advanced cultures; and the occasions for religious acts are rightly noted as being no less social than economic. The importance of native accounts of what happens, and of the native terminology for 'gods', 'devils', and other 'magico-religious' paraphernalia, is also very properly emphasised. The short section (p. 184) on "hero-cult" would have afforded almost no help at all to a field worker in ancient Greece, and would be little more useful anywhere else. Of how many known 'heroes' is it true that "when a hero is associated with war a cult begins to appear"? and when heroes are "associated with death", what does this mean?

Under "Arts and Sciences" the section on "decorative art" has been remodelled, and occasion should have been taken to bring its terminology up-to-date, and emphasise the import-

ance of descriptions to supplement sketches. An unusually detailed specification of 'musical' instruments reflects the current interest in jazz; there are apparently about fifty ways of making a noise by hitting something, and for sheer self-expression give me the "open tubes which are stamped on a man's thigh" (p. 298). The directions for recording native languages are entirely re-written; much doubtless good advice is given; the "wise observer will resist the temptation to invent an alphabet of his own": but the Royal Geographical Society's excellent rules for transliterating place-names (and they can be used for much besides) have been cut out. The alphabet of the International Phonetic Association is recommended instead, but not supplied.

The valuable sections at the end, on photography and the collection of specimens, have been brought up-to-date; and there is a fresh note on the kinematograph, in which the sole omission is advice on the difficult art of bringing scientific films into Great Britain.

For the very moderate price of six shillings, this is a very handsome outfit of instruction, and suggestion also: and the convenient arrangement is continued whereby the book, though prepared for the British Association, is published and distributed by the Royal Anthropological Institute from its library at 52 Upper Bedford Place, W.C.1.

J. L. M.

Early Literature of Acarology.

Tijdschrift voor Entomologie. Uitgegeven door de Nederlandsche Entomologische Vereeniging onder redactie van Dr. J. Th. Oudemans, Prof. Dr. J. C. H. De Meijere en Dr. A. C. Oudemans. Deel 69, Jaargang 1926. Supplement: *Kritisch historisch overzicht der Acarologie.* Eerste Gedeelte, *850 v.C. tot 1758.* Pp. viii + 500. Deel 72, Jaargang 1929. Supplement: *Kritisch historisch overzicht der Acarologie.* Tweede Gedeelte, *1759–1804.* Pp. xvii + 1097. ('s-Gravenhage: Martinus Nijhoff, 1926–1929.)

AMONG the Arthropoda, the Acarina, or mites and ticks, would not generally be considered the most attractive group. It is, therefore, somewhat surprising to find that they have received a large amount of attention from the earliest times. This is no doubt due to the fact that to their presence is attributable a long series of highly disagreeable consequences; and that man himself, his food materials and his domestic animals, have suffered conspicuously from their depredations.

The two parts now published of Dr. Oudemans' historical review contain an exhaustive account of everything that has been written on the subject down to the year 1804; a forthcoming part will carry the story on to the year 1850. The scope of the work being mainly historical, we do not find much space devoted to classification or to minute structural detail; the wealth of information, however, on such points as the external characters, habitat, life-history, and distribution of the various species is amazing, and gives evidence of extraordinary labour on the part of the author. As an encyclopædia of the knowledge of the subject up to the beginning of the last century, these volumes will have a permanent value.

Whether the opprobrious terms addressed in the Iliad by Ares to Athene, and applied by Hera to Aphrodite, can be held to refer to any member of the Acarina may be thought doubtful, but that Dr. Oudemans is right in identifying the tormentors of Argus, the faithful dog of Odysseus, with a well-known species of the Ixodidæ need not be questioned. Other references in the classics that may apply to mites or ticks are numerous, but in many cases there is an evident confusion between the Acarine pest and the true louse, which was naturally not recognised as belonging to another class of the Arthropoda. Aristotle, however, distinguishes clearly between the louse and the tick: the ass, he says, is not infested by either; oxen, on the other hand, suffer from both. Ticks, but not lice, are found on sheep and goats. The name that he gives to the external parasite of the dog is the same as Homer's in the Odyssey; and also in a fable which he attributes to Æsop the same word is used of vermin that were draining the blood of an unfortunate fox.

The uncertainty that besets all attempts at identification of the forms mentioned by ancient authors becomes gradually cleared away as we approach our own times. It is not, however, until the introduction of the binomial system of nomenclature by Linnæus in the tenth edition (1758) of his "Systema Naturæ", that the determination of species becomes to any large extent possible. Some descriptions of an earlier date are, however, sufficiently exact to enable us to be reasonably sure that we know the species referred to. The *Araneus indicus coccineus major*, for example, brought from the coast of Coromandel, and described by Petiver in 1701, is without doubt the mite now known as *Trombidium gigas*. There are, moreover, many records of observations made in the seventeenth and eighteenth centuries which anticipate in a remark-

able manner the results obtained by work conducted on the lines of modern systematics. Among those dealt with by Dr. Oudemans are the discovery by Leeuwenhoek (1694) of the six-legged larva of the mites; the description of the mouth parts of ticks in a letter by an anonymous contributor to the *Philosophical Transactions* of the Royal Society (1703); the observation by Linnæus that *Tetranychus telarius*, commonly known as the 'red-spider', spins threads with which it covers the stems and leaves of trees. A graphic account of the habits of the larval *Thrombidium pusillum* (the too-well-known 'harvest bug'), with some mention of structural details, was given by Baker in 1753. Some years before this the earliest description of the larva of a Hydrachnid, or water-mite, was published by Joblot, who adds to his account a figure, obviously exaggerated, of the dorsal sculpture of this creature, showing a grotesque resemblance to a human face.

In his second volume Dr. Oudemans treats of the further information gained on the whole assemblage since the year 1759; ending his survey with the year 1804. A brief summary is given of the earlier attempts made at a classification of the group, a problem which even at the present day is far from having received a satisfactory solution, Trouessart's scheme, adopted in the main by Warburton in the "Cambridge Natural History", being probably at present the most convenient in practice. By the naturalists of the seventeenth century the term *Acarus* was used in a very wide sense, including, according to Dr. Oudemans, larvæ of Coleoptera, Lepidoptera, and Diptera. Successive approximations to a reasonable restriction of the term were made by O. F. Muller (1769), Fabricius (1775), and Latreille (1795). Dr. Oudemans, being an advocate of strict adherence to the rule of priority in nomenclature, has thought it his duty to revive several of the older names in place of those now commonly used. Thus in the subgenus *Platyseius* he sinks his own specific name *subglabra* in favour of *tendens* Schrank, which dates from 1803. The well-known pigeon-tick, hitherto generally spoken of as *Argas reflexus* Fabr., reverts to its original designation of *Argas columbarum* Shaw. So, too, Latreille's *Caris vespertilionis* (1802) becomes *Acarus testudo* Risso (1790). The author is no lenient critic of mistakes in nomenclature; he does not spare what he considers to be the mistaken following of Neumann in the Cambridge "Monograph of the Ixodoidea".

The numerous illustrations, reproduced from the figures in the original works of authors up to the beginning of the nineteenth century, serve to justify Dr. Oudemans' contention that many Acari were well described and figured in quite early times. There is, nevertheless, much evidence that the producers of these descriptions and figures, careful observers as they were, did not always succeed in appreciating fully the significance of what they saw. Through the maze of conflicting records and determinations, Dr. Oudemans' important work is a safe and sufficient guide.

Apart from a few trifling printers' errors, the only serious misprint that we have noticed occurs in a passage cited from Aristotle on p. 51 of Part 1. Here, though all the words are good Greek, the opening sentence of the speech is unintelligible as it stands. Fortunately the necessary emendation is quite obvious. F. A. D.

Modern Volumetric Analysis.

Volumetric Analysis. By Prof. Dr. I. M. Kolthoff, with the collaboration of Dr. H. Menzel. An authorised translation based on the German Text by Prof. N. Howell Furman Revised and enlarged by the Author Vol. 2: *Practical Volumetric Analysis.* Pp. xiv + 552. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd, 1929.) 25*s*. net.

FOLLOWING on Vol. 1 dealing with the general theory of volumetric analysis, Dr. Kolthoff has produced a work on practical methods which in its way is different from the well-known standard works dealing with the subject. The author does not claim to deal particularly with special methods of applied chemistry, but, as a matter of fact, the general considerations and the exhaustive discussion of general methods suffice to give the reader the necessary indications for accurate procedure. As an example of this, we have in Chap. xiii. what appears at first sight to constitute a general discussion of certain methods. Actually the chapter is a very full description of iodometric processes for both inorganic and organic compounds. The limitations of the methods and the author's experience are given, the discussion of the errors and details being full enough for most purposes: for example, the discussion of the hydroquinone titration on p. 453. A short chapter is devoted to the useful iodate method developed by Andrews, and the use of bromate is likewise properly stressed.

The greatest interest of the book lies in its development of the fundamentals of volumetric analysis. The chapter on calibration of measuring vessels, for example, puts the subject as succinctly

as can be desired from a general point of view. There are some considerations, however, on this matter which might have been further emphasised. It should be pointed out even more strongly than is done in this work that for the highest accuracy in volumetric analysis, the weight burette is essential if drainage and wetting errors are to be avoided. For micro-work these errors are even more important. We are furnished with tables of ' tolerances ' for measuring vessels as laid down by various standardising institutions, but it is not clearly indicated that an error of nearly 0·5 per cent in a volumetric determination of a constituent is possible, even when the highest grade of volumetric apparatus (with the usual tolerances) is used. This is apart from errors due to purity of the standard reagents (see Stott, *J. Soc. Chem. Ind.*, **40**, 64 T ; 1921).

Chap. ii. deals with a most important—and perhaps the most important—requirement of accurate volumetric analysis, namely, the selection of a true standard substance and the specification of such a standard. Wagner, Kühling, Sörensen, and others have advocated rightly the selection of the least number of ' standard ' substances and have laid down certain principles for testing the standard. Various suggestions to this end receive consideration and the arguments advanced by different authorities are considered, with the result that rules are laid down (p. 47) for the requirements of a standard substance, particularly the all-important question of stability and keeping properties. There is one point in this connexion that we do not think receives adequate recognition. It is not difficult to apply certain tests for purity to a standard substance, but an important matter is to determine as accurately as possible the actual content of the standard substance, for example, sodium chloride, by an accepted gravimetric method of high accuracy. Such a test settles the adequacy of the standard, particularly of a stable standard.

In the section dealing with standardisation of acids, a number of primary standards is given, and it is satisfactory to note that the potassium iodate method receives proper consideration. The methods of ' argentometry ' are described in great detail in Chap. viii., which likewise contains a full account of Fajan's adsorption indicators. This section makes pleasant reading, inasmuch as it indicates very clearly indeed that the subject is really a branch of physical chemistry. The last two chapters deal shortly with some of the more recent oxidising agents such as ceric sulphate, and with the general applications of titanous solutions. The work is very fully indexed.

Two points of criticism need to be made, namely, the continued use of the atomic weights of 1925, which includes titanium as 48·1, and the use of c.c. instead of ml. It is difficult to understand the latter feature in a book of this character, so philosophical in other respects. Dr. Kolthoff's two books on " Volumetric Analysis " occupy a position by themselves, inasmuch as they deal with the subject from the point of view of modern theoretical chemistry. The reader cannot fail to perceive a new presentation of old subjects, for example, pp. 279-284 on permanganate oxidations. The whole work is to be commended, alike for the use of students and for general reference.

J. J. F.

A Directory of the Learned World.

Index Generalis : Annuaire Général des Universités, Grandes Écoles, Académies, Archives, Bibliothèques, Instituts scientifiques, Jardins botaniques et zoologiques, Musées, Observatoires, Stés Savantes. Publié sous la direction de Dr. R. de Montessus de Ballore. Pp vi + F170 + BE228 + US213 + E39 + 2322. (Paris : Éditions Spes, 1929-30.) n.p.

IN scope, as indicated by the sub-title, this annual is akin to the well-known " Minerva Jahrbuch der gelehrten Welt ". It is, however, very much less exhaustive, and the two publications differ in the methods of arrangement of their material. " Minerva " presents, gazetteer-fashion, a single series of sections arranged in the alphabetical order of the names of towns. The " Index Generalis " provides a catalogue *raisonné* under the following group headings : Universities and " grandes écoles " (1147 pages), astronomical observatories (95 pages), libraries and archives (270 pages), scientific institutes (118 pages), learned societies and academies (190 pages). Within each of the first four groups the arrangement is by countries ; the last group is subdivided according to subject and, within each subject, by towns, irrespective of country. There is, of course, an alphabetical index of names of persons—65,000 references—and, finally, there are geographical tables enabling one to find one's way to the whole of the information given regarding any particular place.

Many of the notices of the various institutions, etc., some 6500 in number, are in their native languages, where these are French, English, German, Spanish, or Italian. The date (year) up to which the information has been corrected is in most cases

given. Prefixed to the sections relating to the universities of France, the United States of America, Spain, and Italy, are short accounts of the organisation of higher education in those countries. An account is also given of the organisation of studies in the University of London, as being typical of British universities in general. In the index of persons' names references are not merely to pages but also to subdivisions of pages. The pages being small and the names being printed in bold type, this makes the tracing of references an easy matter. Provision is made for enabling authors who wish to exchange original memoirs with others to advertise the fact.

In the preface, contributed by M. Appell, the well-known Rector of the University of Paris, it is claimed as a merit of the method of arrangement adopted that it shows "avec une clarté toute française le rang de chaque pays au point de vue intellectuel": a thankless service, of dubious value, more likely to attenuate than to strengthen those relations on the intellectual plane between the peoples of the world which are to pave the way, according to M. Appell, for the advent of the veritable League of Nations. It would be easy but profitless to compare and comment on the allocations of space in the "Index" to the various countries, but there is one country the almost total exclusion of which compels remark, the more so in that its cultural relations with France were once very close—Russia. The only references under the heading U.S.S.R. are to two astronomical observatories, and the same remark applies to the Ukraine and Turkestan. It would seem that the editor holds the conditions of a socialist State to be such as to vitiate the pursuit of all branches of knowledge, except knowledge of the celestial bodies! Minerva (1930) devotes 59 pages to Moscow alone and gives information about universities at fourteen places in Russia which are not even mentioned in the "Index Generalis".

The preparation of the chapter relating to universities in the British Empire was, or could have been, made comparatively easy by using the "Universities Yearbook of the British Empire". Recourse to this could have prevented such mistakes as omitting the University College of Swansea and London Day Training College, and the teaching staff of the largest English university college for women (Bedford).

Although still marred by deficiencies in regard to balance and too many inaccuracies in detail, the "Index Generalis" has greatly improved since its first appearance in 1919.

Our Bookshelf.

Hyde Park: its History and Romance. By Mrs. Alec. Tweedie (*née* Harley). Abridged revised edition. Pp. vii + 239 + 29 plates. (London: Besant and Co., Ltd., 1930.) 3*s.* 6*d.* net.

THIS is an abridged and revised edition of a book published in 1908, which in many parts has been largely rewritten. For Mrs. Tweedie's point is that of to-day. She brings the story of Hyde Park down to its mobilisation in 1926 during the great strike, and refers to the danger of Socialist proposals to-day for its popularisation as a sports ground. She follows the Park through its many vicissitudes from the grants of land east of Tyburn from the King to St. Dunstan in 960 and of Geoffrey de Mandeville, who fought at Hastings, of the Manor of Hyde to the abbey at Westminster. Under the Tudors after the suppression of the monasteries it became a Royal hunting-ground; but it was not until the return of Charles II. that it really entered upon its function as a centre of social gathering, primarily for the Court and its hangers-on. For long the people were not admitted. Nevertheless, Hyde Park serves as focus for more than one side of our earlier social history. Its neighbourhood was infested with footpads and highwaymen, and Tyburn, with its sinister associations of the hangman and the 'Triple Tree', was within its purlieus.

Mrs. Tweedie's book is an entertaining and gossipy narrative, instructive in its glimpses of English life and history; but she is a mistress of irrelevance. This is not entirely a fault, as it usually permits her to introduce matter which adds colour to her background. Little asides of social incidents and changes to-day, perhaps not even remotely connected with the Park, will have a value for the historian of the future. Their place and meaning become clearer when it is understood that the pageant "Heart of Empire" to be held at the Albert Hall in October next while the Imperial Conference is sitting is based upon the book. No doubt Mrs. Tweedie had in mind the public before whom the book will be brought in this way. They will treasure it in the future when overseas, perhaps most of all for these same little touches from the London of to-day.

L' atomistica moderna e la chimica. Per Dott. M. Haissinsky. Pp. xiv + 315. (Milano: Ulrico Hoepli, 1930.) 35 lire.

THE enormous strides made during the past few years in the knowledge of the inner structure of the atom, developed principally by physicists making use of physical and physico-mathematical methods, have led to the publication of numerous works dealing with this branch of modern physics. The author considered, however, that a need existed for a book dealing with such subjects more from the chemical point of view. In the preparation of the present volume, the requirements of the chemist in particular have, therefore, been borne

in mind, and the treatment adopted should present little difficulty to any reader conversant with the ordinary fundamental conceptions of physical chemistry.

The first two chapters are devoted to elementary notions concerning molecules, atoms, electrons, thermodynamics, and the quantum theory. The third treats of the Bohr atom as the basis of modern atomistics, emphasis being laid on points of immediate importance in the study of chemical problems. The remainder of the book is concerned with atomic chemistry proper, and is dominated by the fundamental idea that chemical phenomena are due to the laws governing physical phenomena in general, namely, the laws of energetics and probability. The extent of the ground covered may be judged from a brief summary of the contents of the book, these including: Electronic theory of valency; Bohr's theory and its applications; electronic structure and ionic radii; deformation of electronic orbits; photochemistry; radiochemical hypothesis; catalysis and adsorption; wave mechanics, and Fermi's statistics.

Each chapter is followed by a useful bibliography, and an author index and a list of the tables included in the text are given at the end of the book. The print is good, the proofs have been carefully revised, and the whole is well up to the Hoepli standard of production. The price is commendably moderate.

Mechanism of Enzyme Action and Associated Cell Phenomena. By F. F. Nord. Pp. ix + 78. (London: Baillière, Tindall and Cox, 1929.) 9s. net.

WITH our present knowledge of enzyme processes any conception of their mechanism must be essentially highly speculative. In the work under notice the author makes no claim to deal comprehensively with the subject of enzyme chemistry, but confines himself to a limited aspect of this wide field. The book deals almost exclusively with the subject of yeast fermentations, while the probably related subject of muscle chemistry and the various other enzyme processes of animal physiology receive little or no attention.

The work of Harden and Young on alcoholic fermentation is summarised and discussed in conjunction with the findings and views of other workers in this field. Evidence for the presence and rôle of intermediate compounds in yeast fermentations is examined, and a short account is given of the information obtained as to the course of fermentation reactions by the use of alkaline sulphite as a means of influencing the part played by acetaldehyde as an intermediary. A whole chapter is devoted to the discussion of the problem of 'activation' of enzymes, and particular attention is directed to the part played by simultaneous reduction and oxidation in fermentation processes.

In its literary style the work is somewhat laboured and occasionally obscure, while the execution of the diagrams also leaves much to be desired in the way of clarity. The information presented has obviously been carefully collated; nevertheless, the reviewer has been unable to find authority for the statement, on p. 10, that the gamma fructose present in cane sugar is partially enolised.

A good bibliography greatly increases the value of the book as a concise presentation of the chemistry of yeast fermentations.

Histoire des sciences mathématiques dans l'antiquité hellénique. Par Prof. Gino Loria. (Science et civilisation: Collection d'exposés synthétiques du savoir humain.) Pp. vi + 215. (Paris: Gauthier-Villars et Cie, 1929.) n.p.

THIS is probably the best short history of Greek mathematics which has yet been published. It has all the clearness and charm of a French popular exposition of a difficult subject; it also gives, unfortunately (in the copy submitted for review), a striking proof of the carelessness of French book-production, fourteen pages being entirely blank!

Prof. Loria gives a brief general sketch of the earliest steps, with the presumed debt to Egypt and Babylonia, takes a conservative view as to Thales and Pythagoras, and reserves most of his space for the later mathematicians whose works are extant. He is particularly good on Euclid, Archimedes, and Apollonius, and enlivens the end of his little book by several examples of the amusing concrete problems in which the Greeks delighted and which were sometimes engraven on the tombs of their ancestors.

There is a very useful short chapter at the end, giving the applications of Greek mathematics to their astronomy and views of the universe. This supplies the link needed in many accounts of early Greek science. The bibliography is well chosen and up-to-date, giving both the latest editions of the texts and the best books discussing the results.

F. S. M.

List of the Vertebrated Animals exhibited in the Gardens of the Zoological Society of London, 1828–1927. Centenary edition in 3 volumes. Vol. 2: *Birds.* By Dr. G. Carmichael Low. Pp. viii + 832. (London: Zoological Society, 1929.) 25s.

A COMPANION volume to that on "Mammals", already noticed in NATURE, and like it a most useful work of reference. It includes the names of 2330 birds which have appeared in the London Zoo, and in addition gives the geographical races of many of the forms. All the essential catalogue information accompanies each scientific name—the most important synonyms, the geographical distribution, references to a good description and to a coloured figure where such exists. The English name or names of each species is given—an important item for the museum official who has to label birds, and, since each name is indexed, for the reader who wishes to know the exact significance of colloquial names used in books of travel and the like. So authoritative a list should help to stereotype the popular names of foreign birds, which are sometimes in danger of having as many popular as scientific synonyms.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

A New Theory of Magnetic Storms.

AN attempt to infer the course of events when a neutral ionised stream of particles from the sun is directed towards the earth has now led to results which we believe indicate how magnetic storms are produced. A full discussion of the phenomena involves the solution of numerous intricate mathematical problems, many of which have not yet been attacked in detail; but it seems possible to outline the main sequence of events.

The motion of a neutral ionised stream in the earth's magnetic field was investigated by one of us in 1923,[1] and it was concluded that the stream would be scarcely deflected by the field, though some slight convergence would occur within about one earth-diameter from the earth's centre O (Fig. 1).

No indication as to how such a stream could produce magnetic storms and auroræ was obtained. It would seem that this failure was due to the assumption there made that the stream had enveloped the earth for a time long enough to enable a steady state to be set up, whereas it now appears that magnetic storms are essentially connected with the *approach* of the stream towards the earth. The important changes in the stream occur within a few earth radii from O, and beyond this distance the former conclusion that the stream travels almost without deflection remains valid.

The stream is in effect a highly conducting body, and as it enters the earth's field electric currents flowing parallel to its surface are induced in the surface layers, so that the interior of the stream is nearly shielded from the earth's field. Outside the stream the magnetic effect of the currents is roughly equivalent to that of an 'image' magnetic doublet at a certain point inside the stream; in the equatorial plane the field between the earth and the stream is increased in intensity. It is as if the current layer, as it advances towards the earth, pushes forward and crowds together the earth's lines of force.

We identify this change with the observed increase in the earth's horizontal force during the first stage of a magnetic storm. Detailed examination shows that the magnitude of the effect, and its time scale, depend almost entirely on the kinetic energy of the stream per unit volume; if the velocity of the stream is of the order 1000 km./sec., the density requisite to explain the first phase of an average magnetic storm (taking account of the shielding effect of the Heaviside layer) is roughly of the order 10^{-22} gm./c.c.; this might be provided by about 1·5 calcium ions or 60 hydrogen ions per c.c.

The magnetic energy of the field is increased during this phase at the expense of the kinetic energy of the stream; the retardation of the particles occurs in the current layer, which is continually increased in mass-density by the oncoming of particles from behind. The retardation is greatest at that part of the front of the stream (A in Fig. 1) which is moving along the direct line from the sun to the earth's centre O; on either side of A the stream will advance relatively to A, and the earth will become partly enclosed by the stream; the surface $B'BACC'$ will continually close in, at a diminishing rate, upon the earth; whether it actually reaches the earth's atmosphere, in the equatorial plane, will depend on the density of the stream, and the length of time during which it is directed towards the earth (this is determined by the angular breadth of the stream viewed from the sun).

In the second (which is the main) phase of a magnetic storm the earth's horizontal force is decreased. We attribute this to the formation of a westerly current round the earth, due primarily to the flow of charges across the space 'behind' the earth (viewed from the sun). Along the sides BB', CC' of the enclosure there will be charged layers, BB' positive and CC' negative, due to the polarisation of the stream by the magnetic field. The charges in these layers will be subject to an outward electrostatic force, and the positive ions along BB' will cross over to CC', partly guided by the earth's field. The electrons along CC' cannot flow along the reverse path because of the greater deflecting influence of the field upon them, but negative charges from 'above' and 'below' the equatorial plane will travel along the earth's lines of force to neutralise the charge of the ions moving from BB' across the gap. The details

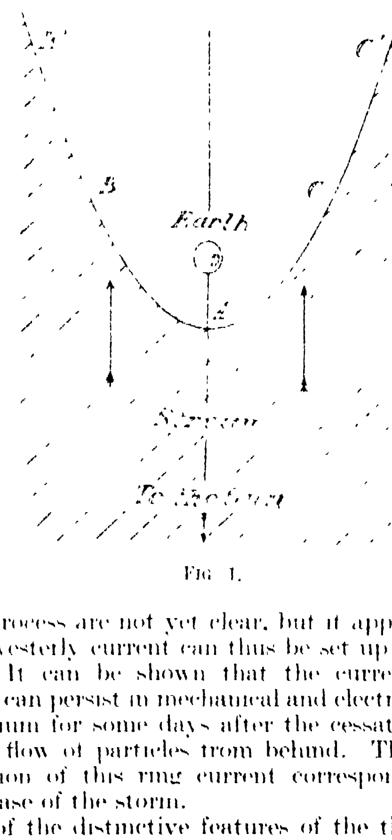

FIG. 1.

of the process are not yet clear, but it appears likely that a westerly current can thus be set up round the earth. It can be shown that the current-ring, if formed, can persist in mechanical and electromagnetic equilibrium for some days after the cessation of the onward flow of particles from behind. The gradual dissipation of this ring current corresponds to the final phase of the storm.

One of the distinctive features of the theory here outlined is the distance from the earth within which the main electric currents flow, namely, a few earth radii: they are outside the earth's atmosphere (though secondary currents are induced therein), but they are much nearer the earth than the currents (in the equatorial plane) discussed by Birkeland, or the equatorial current proposed by Prof. Stormer and associated by him with the decrease of latitude of auroræ during magnetic storms.

We have not examined closely the extent to which the stream will cause inflow of ions and electrons into the earth's atmosphere in the polar regions, or how this inflow will give rise to the observed currents along the auroral zones; but it seems likely that present theories of the auroræ will need to be modified, because the particles of a neutral stream can approach much closer to the earth, in the equatorial

plane, than the single charged particles hitherto considered. This must also have an important bearing on the theory of radio echoes, should it be proved that these are produced outside the earth's atmosphere.

Method of obtaining a Visible Spectrum of Waves of Radio Frequency.

IN the course of a research on the heating effects of radiation of wave-lengths 10 to 200 metres, it was found that for a given wave-length there is a maximum heating effect produced in a medium the specific conductivity and dielectric constant of which are connected with the frequency by a simple law. This law, proved theoretically as well as shown experimentally to hold for dilute solutions, is

$$\frac{2c}{nD}=1,$$

where c = specific conductivity in absolute units, D = dielectric constant, and n = frequency of wave. This law accounts for the curious selective heating effects observed in such high frequency fields, which give promise of great application in medical science.

The above relation suggested that it might be possible to produce a spectrum of a radio-field, where

FIG. 1.

a line would by its position in the spectrum indicate the wave-length emitted by a valve oscillator. A jelly of about four per cent agar-agar in distilled water was impregnated with finely powered tetriodomercurate of silver. This substance is orange-red when hot and canary-yellow when cold, the change being quite sharp at about 35° C. (It is used and described by Pariseau, *Can. Med. Assoc. Jour.*, 20, 146; 1929.) A glass tube was filled with the jelly, a small section at a time, a few drops of an electrolyte being added to the hot jelly before each addition, so that the conductivity increased as we passed along the tube. When the completed tube was placed in the field of radiation of an oscillator, it was found that if there was sufficient intensity, a red patch appeared in the jelly in a position where the conductivity was that determined by the relation given above. The accompanying photograph (Fig. 1) shows how the device acts as a crude spectrograph. The colour change is quite marked but is difficult to record photographically.

Neither the dispersion nor the resolving power are at present great, but an attempt is being made to prepare a film of the substance in which the conductivity will vary continuously. Interesting results might be found with ultra-short waves, as any changes in the dielectric constant would show themselves as anomalous dispersion, as do changes in the refractive index with light.

Isolation of the Film Responsible for the Passivity of an Iron Anode in Acid Solution.

A RECENT paper (*J. Chem. Soc.*, 1930, p. 478) showed that the *direct* solvent action of dilute sulphuric acid on ferric oxide films is very slow. The *rapid* removal of a ferric oxide film from iron by acid is due to the formation of the local cell iron/acid/ferric oxide, which produces cathodic reduction of the ferric oxide to the rapidly soluble ferrous oxide. If the whole surface receives anodic treatment, this cathodic reduction is prevented, and hence an iron anode may remain passive in acid solution.

Further work has now shown that it is possible to isolate the film responsible for this type of passivity. The electrodes used consist of cold-rolled electrolytic iron abraded with No. 1 emery and degreased in carbon tetrachloride. The anode, fixed at 70° to the horizontal at a distance of 4·5 cm. from a vertical cathode, is viewed continuously through a binocular microscope. The electrolyte is normal sulphuric acid, and time is allowed for the dissolution of any 'air-formed' films. An e.m.f. of 6 volts is then applied to the cell; the anode at first is active, suffering corrosion, but soon passivity sets in, and evolution of oxygen commences. If the circuit is now broken for a short time, and restored, the anode is found once more to be active, and iron passes into solution; in due course, passivity returns, and in this way the iron can be made active and passive alternately.

Microscopic observation shows that during the passive periods, the anode is quite bright; but when, after the 'off' period, the current is again turned on, a series of horizontal shadow-fringes pass upwards over the surface, due to the wrinkling of a surface film. This film must have been present in optical contact with the metal during the passive stage; but it only becomes visible when the metal immediately below it is dissolved away. By alternately making and breaking the circuit (with variation of the e.m.f. between 4 and 6 volts, if required), it is possible to separate the transparent film intact from the electrode over quite large areas. Success depends on making and breaking the circuit at the right moments, chosen by watching the appearance of the skin through the microscope. The current is employed to undermine the skin, and prevent its destruction, whilst the 'off' periods serve to produce the local failure of the skin required for the commencement of undermining, and at later stages may be used to destroy the film at any points where it adheres too obstinately to the metal (this destruction is caused by the formation of the local cell iron/acid/oxide).

The film is less easy to preserve than that obtained from iron rendered passive in potassium chromate solution (*J. Chem. Soc.*, 1927, p. 1020); the fragments readily twist themselves into masses recalling 'cobwebs', whilst in some cases the film, as it peels from the anode, rolls up 'like a carpet' into long tight rolls, which under low magnification may be mistaken for fibres. But although mechanically flimsy, the films are stable chemically and can survive an hour in normal sulphuric acid, provided they are free from

metallic iron. Some specimens of iron have yielded a skin containing opaque inclusions—no doubt a further example of the 'interlocking' of oxide and metal studied in earlier work (Evans and J. Stockdale, *J. Chem. Soc.*, 1929, p. 2651).

The results confirm the views of Hedges (*J. Chem. Soc.*, 1928, p. 976), that anodic passivity—like other types—is due to a protective film. Since Benedicks and Sederholm (*Z. Phys. Chem.*, **138**, 123; 1928) have photographed the film which causes passivity in nitric acid, it may now be claimed that, for each important type of passivity, the film responsible has been rendered visible.

The removal of oxide-films by the cell iron/liquid/ferric oxide, which takes place so rapidly in acid, occurs slowly in neutral solutions. Mr. S. C. Britton, working in this laboratory, has found that heat-tinted iron kept in oxygen-free $N/10$ potassium chloride for two weeks loses its colour; a similar treatment appears to be capable of removing much thicker films, such as mill-scale, and also films too thin to be visible: the removal proceeds at least in part by undermining. These facts may explain the important discovery of McAulay and Bastow (*J. Chem. Soc.*, 1929, p. 85), who found that mere immersion in oxygen-free potassium sulphate brought iron specimens to a 'standard state', in which subsequent movements of the electrode potential were reproducible and independent of the previous history.

Nutritional Status and Sex Determination.

RECENT correspondence in NATURE (R. R. Gates and D. V. Daran, Mar. 1, p. 309, and D. M. Cayley, April 5, p. 527) indicates that diversity of opinion still exists in regard to the question of 'multiple sexes' or 'nutritive heterothallism' in the fungi. The lower plants have yielded a great deal of information of a fundamental nature on sex, and the outcome of such correspondence must certainly be a further advance of knowledge with its applications not restricted to the fungi.

Nutritional status was long ago considered to play a part in sex determination in animals, but, largely through lack of well-controlled experiments, the idea lost favour. Nevertheless, evidence from a variety of sources is redirecting attention to the question. That nutritional state, without any relation to such phenomena as parasitism, may affect the ultimate sex expression in insects is the conclusion I have reached as a result of studies on the 'flour beetle' *Tribolium confusum* Duval. The evidence will be published in greater detail in the near future, but a summary at the present time may be of interest.

The sex ratio of newly hatched unfed larvæ, under controlled conditions of temperature, humidity, light, nutrition of the parents, and subsequent nutrition of the larvæ, has been altered by starvation. The alteration in sex ratio was not due to differential mortality of the sexes, since the change was considerably larger than the total mortality up to pupation, when it was possible to determine the sexes by genitalia characters. (The mortality ranged from 0 to 2 per cent, with an average of 1·2 per cent.) However, the change in sex ratio is not a simple relation between starvation and the production of a preponderance of one sex, or between time of starvation and resultant sex ratio, for with one day's starvation there is an increase in the preponderance of males, while with two and three days' starvation the number of males decreases and there is a preponderance of females. The net result is that while life lasts there is an oscillation of the sex ratio. Graphically, the curve representing this oscillation has an axis which slopes somewhat from a slight excess of males to a lower proportion of males with increase in starvation period.

The oscillating nature of the change in sex ratio indicates that either some forms change from one sex and back again, or that certain forms of both sexes change to the other sex after different periods of starvation. The conclusions reached are that either:

1. A proportion of the population is stable as regards its expression of sexuality, while a proportion is more easily converted to the opposite sex one way or the other; or

2. That forms of either sex may be changed to the opposite sex but that there are gradations of sexual stability only upset after varying periods of time.

The effect of nutrition on sex determination undoubtedly takes place *per medium* of its effect on the biochemical and biophysical state of the body fluids, and through them also on the germ cells. In insects one does not consider that more than two sexes occur, but the results briefly quoted above indicate that there are at least gradations in constitution which show a relation between nutritional status, dependent on time of starvation, and the ultimate sex expression.

A New Band System probably due to a Molecule CP.

WHEN investigating the band spectra of phosphorus I tried a discharge in a mixture of argon and phosphorus vapour. This discharge, with suitable arrangements of the concentrations of the two gases, shows an intense and extended band system in the wave-length region λ4000-λ2900 A, which does not occur in pure phosphorus vapour. So far as I am aware it has not hitherto been recorded. At the same time the Swan bands of the C_2 molecule are very intense in the visible region, obviously due to tap grease and sealing wax. As in a mixture of argon and a small trace of nitrogen, under the same conditions of discharge, the CN bands are specially strong (the C_2 bands of course also being present), it seems very probable that the new band system is due to a molecule CP which would be the analogue of CN. So far as I know, such a molecule, or a molecule $(CP)_2$ which would be analogous to $(CN)_2$, has not been found chemically. If the above conclusion that the new band system is due to CP is correct, it might be possible also to get chemical evidence of some simple CP compound. In order to obtain a further test of the above conclusion, an attempt is being made to get exposures strong enough to show the bands due to the isotope molecule $C^{13}P$ which would make possible a definite identification of the emitter of the bands in question.

The structure of the band system and the single bands is very simple and in agreement with the assumption that they are the analogue to the $^2\Sigma$-$^2\Sigma$-CN bands. The fine structure is clearly resolved except near the heads. Only one R- and one P-branch seem to be present. The distance between head and origin of the bands is very small, corresponding to a large alteration of nuclear distance. A preliminary vibrational analysis yields the following formula for the heads:

$$\nu = 29103{\cdot}6 + [832{\cdot}4(v' + \tfrac{1}{2}) - 5{\cdot}44(v' + \tfrac{1}{2})^2] - [1239{\cdot}0(v'' + \tfrac{1}{2}) - 6{\cdot}75(v'' + \tfrac{1}{2})^2].$$

The above formula does not represent all the bands which have been found, because there are certain striking perturbations in the vibrational levels of the upper state involved. The 3rd, 4th, and 5th vibrational levels of this state are shifted in the direction of higher energy by an approximately constant amount of about 4·5 cm.$^{-1}$ (the measurements being accurate to within 1 cm.$^{-1}$ or probably less). This is seen especially well in the ω-curve for the upper state, which is approximately linear, only the 2nd and 5th points lying far off it by about the same amount but in opposite directions. Similar perturbations have been found in an extended band system of P_2 (λ3500-2000 A.) which is also under investigation.[1] In this case these perturbations make the vibrational analysis very difficult because they occur both in the upper and in the lower state.

Differentiation in the Dartmoor Granite.

IN his presidential address to the Devonshire Association on June 24, Mr. R. Hansford Worth devotes a section to a brief survey of Dartmoor geology and states, *inter alia*, that he cannot accept the idea of differentiated types of varied age for this granite mass.

As Mr. Worth points out, the granite as a whole is remarkably uniform in type, despite textural contrasts. But variants from the standard type are numerous, and their time-relationship to this type is often demonstrable.

Classified according to the C.I.P.W. system (based on detailed chemical analyses), these variants range from "II. 4. (2)3 . 3(4) to I . 4 . 1 . 2", with extreme types represented on one hand by highly biotitic vein-occurrences and, on the other, by considerable masses of quartz-felspar eutectic and pegmatite. The great bulk of the granite varies little from the type I . 4 . 2 . 3 which may be conveniently adopted as the standard. But the symbols for a suite of thirty granites representative of East Dartmoor, for example, reveal a graded and significant variation, which is more clearly shown in the following table:

	SiO_2. Per cent.	K_2O. Per cent.	Na_2O. Per cent.	Total Alkalies. Per cent.	CaO Per cent.	MgO Per cent	Total Iron Oxides Per cent.
Coarse granitoid inclusion in tor-granite "II . 4 . (2)3 . 3(4). . .	57·4	3·98	1·89	5·87	3·68	3·63	9·23
Tor-granite (Saddle Tor) I . (3)4 . "2 . 3.	71·69	4·59	3·03	7·62	1·49	0·66	2·50
A quarry-granite intrusive into tor-granite (Haytor) I . 3(4) . 1 . 3.	73·66	5·02	2·89	7·91	0·67	0·45	1·72
A typical aplite (Jordan) I . (3)4 . 1 . 2".	76·32	7·51	2·00	9·51	0·40	0·02	0·11

(Analyses by H. F. Harwood.)

In West Dartmoor, variation is still more striking.

Notwithstanding this wide range of mass-composition, biotites separated and analysed prove to be varietally identical, and are associated with the same characteristic accessory minerals.

Essentially the same variation-trend is displayed by many granite complexes, both British and foreign, in which the mass-relation between differentiates and standard types also varies. As applied to such composite granite masses, 'stages of intrusion' imply nothing more than brief local pauses in the intrusion process.

The variation briefly indicated above is closely concerned with the tectonic history of the Dartmoor granite, its anatomy, and its space-form in relation to the country rocks and to the granites farther west. These problems are complex indeed, and admit of amicable and stimulating exchanges of opinion.

Influence of Nitrogen Dioxide upon the Ignition Temperature of Hydrogen-Oxygen Mixtures.

H. B. DIXON has observed that the ignition temperature of hydrogen-oxygen mixtures may be lowered so much as 200° C. by small quantities of nitrogen dioxide. Hinshelwood[1,2] and his co-workers, who investigated this reaction afresh, found that the nitrogen dioxide concentration must lie between two definite limits to give the observed effect, and when the nitrogen dioxide concentration is above or below these limits, only a slow combination of hydrogen and oxygen ensues. Up to the present, it has not been possible to give a satisfactory explanation of the phenomenon.

Now, according to Mecke,[3,4] one of the oxygen atoms in nitrogen dioxide is relatively weakly bound (77 Cal.). On the other hand, in the chain mechanism proposed by Bonhoeffer[5] and Haber[6] for the hydrogen-oxygen combination, reactions are involved which are considerably more exothermic than 77 Cal.

It is legitimate to assume that the nitrogen dioxide is especially fitted to take up the energy of the 'hot' molecules produced in these reactions and then dissociates thus: $NO_2 \rightarrow NO + O$. The oxygen atom formed in this manner can then cause further reaction to take place. When the nitrogen dioxide concentration is great enough to form sufficient oxygen atoms, explosion takes place at a lower temperature.[7] (This is the lower limit of nitrogen dioxide concentration.)

Again, it has been shown[8] that the reaction I.,

$$O + NO_2 \rightarrow NO + O_2$$

takes place more frequently than the reaction II.,

$$O + H_2 \rightarrow OH + H,$$

when it is assumed that the oxygen atom is not very strongly excited, which is, however, scarcely the case in these examples. The three body collision reaction, $O + H_2 \rightarrow H_2O$, which yields very 'hot' molecules, is likewise slower than reaction I.

Hence it follows that when the nitrogen dioxide concentration rises, the probability of the oxygen atom disappearing through reaction I. becomes greater and greater, until eventually the nitrogen dioxide concentration reaches a point where no explosion due to oxygen atoms develops. (This is the upper limit.) Taking suitable values for the velocity and the mechanism of an individual reaction, it is possible to derive the sharp limiting values of the nitrogen dioxide concentration observed by Hinshelwood (loc. cit.). The influence of nitrogen dioxide upon the ignition temperature of $CO + O_2$ mixtures found by

Sagulin and Semenoff[9] likewise finds a similar explanation.

Photography on Copper.

DURING a metallographic examination of some copper alloys it was observed that certain etching reagents produced a surface which was light sensitive to such a degree that the illuminated area of the specimen turned black during a few seconds' examination under the microscope. The phenomenon has been investigated, and found to depend upon the well-known light-sensitivity of cuprous chloride. The process affords a simple and rapid method of obtaining a sharp photographic image on the surface of plates of copper and copper alloys, including white alloys like German silver. It appears, however, to have escaped observation, and a brief description may therefore be of interest. It seems possible that the process may have some technical application, although I do not know of any, and I should be glad to give further information to anyone interested.

The copper or brass surface is polished and cleaned as for engraving, and dipped for ten seconds into a ten per cent solution of cupric chloride or copper ammonium chloride. A very thin white film, which X-ray examination shows to be cuprous chloride, forms on the surface of the plate. The plate is washed in running water, rinsed in methylated spirit, and dried in the air. The methylated spirit not only accelerates drying, but also makes the film much more adherent, and the wet plate can be wiped with a cloth without the film being destroyed. The plate is now light sensitive. On exposure for a few seconds to the direct light from an arc lamp the surface turns black, owing to the conversion of cuprous chloride into cuprous oxide. For contact prints from ordinary negatives an exposure of about one minute to the light of an arc lamp is required. The image (positive) so obtained is about equal in definition and contrast to that obtained in the ordinary three-colour and photogravure processes. The image can be 'fixed' by washing in dilute hypo or salt solution, but since this also reduces the intensity of the image the plate should be over-exposed during printing. For many purposes, such as engraving, fogging by diffuse daylight is so slow that fixing is unnecessary.

Absorption Band Spectrum of Chlorine.

As a mistake which I made in a paper under the above title appearing in the June issue of the *Proceedings of the Royal Society* has been repeated on p. 989 of NATURE of June 28, I should like to direct attention to it and to correct it. In the publication first referred to, I refer to "Aston's figure for the relative abundance of Cl_{35} and Cl_{37}". Dr. Aston informs me that he has never made a direct measurement of the isotope ratio of chlorine, or published a value for it calculated from his work.

The value 1·67 which I gave as the calculated ratio of $Cl^{35}Cl^{35}$ to $Cl^{35}Cl^{37}$ was derived by using the figure 3·35 : 1 for the ratio Cl^{35} to Cl^{37} calculated by F. W. Loomis (*Astrophysical Journal*, 52, 248; 1920), and quoted on p. 156 of "Isotopes" (F. W. Aston, second edition). Dr. Aston has kindly pointed out to me that the masses of the chlorine atoms (correcting for O^{17} and O^{18}) are 34·980 and 36·976 ± 0·006 for Cl^{35} and Cl^{37} respectively. Using the atomic weight 35·457 and these figures, the ratio Cl^{35} : Cl^{37} becomes 3·185 : 1, giving the calculated ratio $Cl^{35}Cl^{35}$: $Cl^{35}Cl^{37}$ = 1·59 : 1. This value agrees slightly better with that found from the band spectrum intensities, namely 1·35 : 1 (this is incorrectly given on the first line of p. 656 of the publication first referred to as 1·45 : 1; Table VII. of the same paper gives the correct value).

Effect of Magnetic Fields on Dielectrics.

PROF. BURNS in his letter in NATURE of July 12, p. 59, observes that he has found a decrease of power factor when a magnetic field is superimposed on a dielectric, normal to the alternating electric field, and refers to my paper on dipoles (*Phil. Mag.*, May 1930). The view that such effects may arise from the existence of a magnetic as well as a dipolar moment is tempting, although cursory consideration of magnitudes suggests that such an effect is likely to be small.

Smouroff, however, has investigated the effect of magnetic fields upon dielectrics from atomic and ionic considerations ("Int. Congress of Math." (Bologna), Sept. 1928, *Arch. El.* p. 31, 1929). On his theory a decrease of power factor appears possible in some cases, but it would seem more usual to expect an increase in power factor. Monkhouse (*Proc. Phys. Soc.*, vol. 31, p. 83) has made experiments upon the electrical breakdown of dielectrics in magnetic fields and also mentions that large increases of power factor have been observed in agreement with Smouroff's theories.

With solids a longitudinal field appeared to have much more effect than a transverse field. In absence of experimental details it cannot be concluded that these results are contradictory, but a further examination might give interesting information upon the limitations of Smouroff's theory and the applicability of an extension of the dipole theory.

A Study of the Phenomenon of Spin in Airplanes.*

By H. E. WIMPERIS, C.B.E.

THE spin is a mode of motion of which we know very little. The general public are inclined to look upon it as necessarily dangerous, but this we do know it is not. It is only in rare circumstances and under fortunately rare conditions that danger arises. Nevertheless there is ample warrant for its study and for that study to be treated as one of high importance. New conditions of airplane operation are continually arising; the very increase of speed itself would ensure an entry into regions never before penetrated. Hence it is ever necessary to seek for remedies even before serious difficulty has arisen. This anticipating action always seems to me to be absolutely essential, and I am comforted by support in this view from no less an authority than Francis Bacon, who, in his essay "On Innovations", wrote: "Time is the greatest innovator; and if time in course alters things to the worse, and wisdom and counsel shall not alter them to the better, what shall be the end"?

So we have ahead of us the difficult task of diagnosing not so much actual diseases as mere symptoms, and of devising in anticipation suitable remedies. Spins from which recovery is difficult may be rare, but since from time to time they are reported, a vigorous investigation becomes necessary. Though that investigation is far from having been completed —indeed in some ways it is little more than begun — the interest taken by everyone in flying makes some account of our present efforts worth attempting, whilst the very complexity of the phenomenon is in itself a challenge.

THE SPIN.

The first step will be to describe what constitutes a spin, why certain forms of spin present difficulty, why the obvious remedies fail, and the form which the studies now in hand have taken.

Almost all airplanes are built nowadays to be stable in flight; if any small disturbance to their normal attitude occurs the craft tends by its own virtue to return to its previous attitude. The naval architect has always aimed so to design ships that they have this great quality. Indeed, a ship the stability of which depended upon the clever balancing action of its steersman would be decidedly unpopular.

Now, how does an airplane achieve stability? If one suspends a model airplane from a point above its centre of gravity it hangs in stable equilibrium. If slightly displaced it returns. When gliding in flight the upward pull of the string has to be replaced by the resultant of all the upward air forces on the wings and tail plane. If stability is to be obtained, this vertical resultant must pass through the centre of gravity of the craft. The usual way of ensuring this is to give an upward tilt to each wing (the dihedral angle), so that the air forces on the two sides are inclined and meet at a point in the vertical plane of symmetry. The relative inclinations of wing and tail plane can be adjusted in just the same way, and thus the resultant of all the vertical air forces is made to pass through the centre of gravity so that the airplane behaves as though suspended at an imaginary point above the airplane.

This is the condition of ordinary straight flight: centrifugal force does not come into the picture. With circular motion, however, it does. The airplane banks as it turns, the air forces bank with it, and their resultant force balances gravity by its vertical component and the centrifugal force due to the turn by its horizontal one. Hence motion in circles can be just as steady and just as normal as in straight flight. Inconvenient and even dangerous as the actual spin may sometimes be, the spinning airplane is not, so to speak, conscious of doing anything wrong. Its behaviour is purely normal and quite virtuous. There is nothing in it to suggest the vicious circle. When the radius of the turn is made gradually less and less, the angle of bank grows greater and greater until the vertical component of the air forces can no longer balance gravity and the nose drops; the motion then becomes a kind of tight corkscrew. The motion is still steady and is quite safe. It is safe because the pilot can convert the motion into ordinary straight level flight whenever he wishes to do so. If, however, the corkscrew is made tighter and tighter the motion of the airplane may suddenly change to one in which the air forces on the machine will automatically tend to make it tighter still. This is the spin.

Before the essential features of the phenomenon of spin can be grasped, it is necessary to consider in slightly more detail the nature of the forces which act on the wings of an airplane.

AUTOROTATION.

Airplane wings are of various shapes—some have concave undersurfaces and some convex—but all alike when inclined at an angle to the wind (the angle of incidence) give rise to an upward lift force and a small rearward drag. It is important to notice the manner in which the lift force changes as the angle of incidence increases. To begin with, the lift force doubles for each doubling of this angle, but once the latter has reached a certain amount, the lift force increases less rapidly until at a particular angle (known as the angle of stall and usually about 20°) the lift force ceases to increase at all, and instead falls off rapidly as the angle is still further increased. When this happens there is produced a new phenomenon altogether. For if any sudden 'bump' in the atmosphere causes the right wing (let us say) to drop and therefore to meet the air at a steeper angle, the lift force on that wing will *ipso facto* become less and the wing will tend to drop still further. In fact, the whole wing will tend to go on turning. This is the phenomenon of autorotation. It can easily be exhibited in a wind

* Discourse delivered at the Royal Institution on Friday, May 2.

tunnel by so mounting an aerofoil about a suitable axis as to give it a large angle of incidence ; once the air stream is turned on the aerofoil will be found to be quite ready to rotate in either direction once some external cause has given it an initial push in that direction. (An experimental demonstration of autorotation was given at this point.)

The speed of autorotation depends upon the aerofoil section and the angle of incidence. In the case of a complete airplane it depends also on the disposition of the wings particularly in relation to each other and upon the arrangement of parts in the tail of the machine. It is the existence of the many factors which govern the occurrence and speed of autorotation which makes the study of the spin so complicated, that unless the problem is reducible to a few bare essentials a purely theoretical solution is scarcely to be anticipated.

When describing the tight corkscrew as a mode of motion I mentioned that this motion might suddenly change to the spin. This will happen if the angle of incidence should rise to the value at which for that particular wing section, and aerodynamic arrangement, autorotation sets in. Thereupon the forces acting on the airplane speed up the rotation and tend generally to take charge. Sometimes the machine is said to be 'locked into' the spin, but this language though understandable is really over strong, since the pilot by putting down the nose of the craft can bring the angle of incidence below that of autorotation ; at once the autorotation couple dies away and the spin ceases.

How is a true mental picture of this complicated motion to be made? There are the resultant air force, the centrifugal force, and the gravitational attraction all acting on the airplane. We know that the last-named always acts vertically downwards, whilst the centrifugal force acts at right angles to the axis of spin. For equilibrium these forces must be balanced by the air forces, hence the resultant of these latter must have a vertical component equal to the weight, a horizontal and radial component equal to the centrifugal force, and a horizontal and tangential component of zero. This last has to be zero, since in steady motion there can be no acceleration in that direction, and any force necessary to drag the tail round must be supplied by a suitable component of the air forces which act on the aerodynamic surfaces. The resulting motions are known, but no disentanglement of the various air forces due to lift, drag, and sideslip has yet been made.

It was Bairstow who first suggested that the phenomenon of spinning could be imitated in a wind channel by setting an aerofoil at such an angle that self-rotation must occur. This is made clear in an Aeronautical Research Committee report dated October 1918. In this report Relf and Lavender showed not only why autorotation took place, but also how to calculate the rate of spin. Model tests showed excellent agreement with their prediction. The rate of spin was found to increase with the angle of incidence, and in a chosen example the rotational speed rose from about $1\frac{1}{2}$ spins per second to 2 spins per second when the incidence was increased from 20° to 30°.

It is clear from what has already been said, that a lift curve which did not drop after the stalling point would be much less likely to lead to autorotation, or would in any case delay it to so large an angle of incidence that it would be very rare for an airplane to be in the attitude at which spinning could occur. The so-called 'flat-topped lift curve' has this virtue in varying measure, as also have airplanes with slotted wings, for then the stalling angle is very large and could usually only be reached, if at all, by a deliberate jerk to the whole machine. Getting into a spin would then be a piece of voluntary aerobatics and not a pitfall awaiting the unwary. 'Pitfall' may seem a strong word, especially as the phrase of 'locking into' a spin has been deprecated on the ground that, after all, the pilot holds the key of the motion in the right use of his control levers. It seems, however, that certain forms of airplane have so high an autorotation couple that, given time to attain the full corresponding rate of spin, the centrifugal forces due to the unsymmetrical distribution of mass in the airplane may oppose and overcome the control force exerted by the pilot's actions, and this may happen the more readily on account of the spin having become so flat (the airplane being less inclined to the horizontal plane than the vertical) that the control organs in the tail, in the fin, and rudder, are shielded from effective action by the tail plane. At the same time the physiological action of the rotational forces on the pilot may hinder his actions. If one casts a kind of airstream 'shadow' at 45° behind the tail plane, it will be seen that but little of the fin and rudder area can be effective in slowing up the undesired rotation or indeed in affecting it in any way.

The most elementary way of preventing this rapid spin from developing is to increase the size of the vertical tail surfaces, the fin and rudder, and to lengthen the fuselage so that a greater leverage is available. This leads to an increase of weight in the tail, and puts the centre of that weight still farther aft; both these actions lead to an increase in what are called the inertia couples due to the centrifugal force. The effect of these inertia couples is, as I will describe in a moment, to oppose the pilot's control of the machine, and so neutralise wholly or partly the good effect, from another point of view, of the larger tail surfaces and greater leverage. Nevertheless, there is sometimes an advantage on balance to be gained in this way, and for some time a ready criterion of spinning tendencies was used in America which depended principally upon whether or not the tail organs were inside a semicircle based on the wing span.

INERTIA COUPLES.

The effect of an inertia couple can be illustrated by taking the simple case of a rod having equal heavy masses at each end and pivoted at its centre of gravity. If one holds such a system at arm's length and turns round rapidly the rod takes up a horizontal position. This happens because the

centrifugal force on each mass is proportional to its radius of rotation, hence the mass which starts farthest out tends to go still farther out, and stability is only reached when the rod is at right angles to the axis of rotation. If a second similar rod were fastened at right angles, the forces upon it would balance those on the first rod. The combination would be neutral and would take up a neutral position. Hence an airplane with its masses symmetrically disposed would be free from such couples and free therefore from the peculiar difficulties of a flat spin. In practice, however, airplanes cannot be so made, and as a fair example of what occurs in practice the case of the well-known Bristol Fighter airplane may be cited. Here the moments of inertia about the longitudinal axis and the transverse axis are found to be about equal, whilst that about a vertical axis is half as much again.

A simple calculation shows that for any given rate of rotation this disturbing couple reaches a maximum when the fore and aft line of the airplane is inclined downwards at 45°. Once that angle is exceeded the couple grows less. When, therefore, an airplane is being brought out of a very flat spin the pilot has to exert a control not merely large enough to balance the inertia couple at the moment, but also large enough to overbalance this growing couple as the barrier angle is reached. The barrier angle will come at exactly 45° if the rate of spin remains constant, if it does not it may be somewhat above or below this angle. But a barrier there will in general always be, and recovery from any flat spin must depend on its being satisfactorily surmounted. (An experimental demonstration was given to show the effect of the inertia couple in raising the nose of the fuselage.)

A typical pilot's impression of the change from the ordinary spin to the flat spin appeared in one report as follows: "After the first two or three turns, which were relatively steep, the nose came up and the machine settled down to an exceptionally steady spin at moderately large incidence and a quick rate of rotation. There was no noticeable jerkiness during the turn."

(*To be continued.*)

The Bristol Meeting of the British Association.

PROGRAMMES OF SECTIONS.

MATHEMATICAL AND PHYSICAL SCIENCES.

THE presidential address of Section A (Mathematical and Physical Sciences) will be delivered on Monday, Sept. 8, by Dr. F. E. Smith, who has chosen as his subject "The Theories of Terrestrial Magnetism." On each of the other days a considerable portion of the available time will be taken up by a series of related papers. Thus on Thursday, Sept. 4, there will be a discussion on "The Meteorological Relations of Atmospherics," in which Dr. R. A. Watson Watt, Prof. E. V. Appleton, M. R. Bureau, Dr. F. Schindlehauer, and Mr. M. A. Giblett will participate. On the following day there will be a series of papers dealing with aspects of the solid state, the contributors being Prof. J. E. Lennard-Jones, Prof. W. L. Bragg, Dr. J. D. Bernal, and Dr. F. Bloch. These will be followed by a brief discussion, opened by Prof. Heisenberg. On Tuesday, Sept. 9, there will be a discussion on flow in gases, and the aerodynamical and meteorological aspects of this subject will be dealt with by Mr. E. Ower, Mr. F. C. Johannsen, Mr. G. Bilham, and Mr. M. A. Giblett. The programme contains also the usual papers on particular investigations.

Many distinguished foreign visitors are contributing to the proceedings. In addition to those mentioned above, Prof. M. Siegbahn will present a paper on "The Highly Ionised Spectra in the Extreme Ultra-Violet," and the section will probably listen to other eminent visitors.

There will be a strong Sub-Section of Mathematics, and twenty papers appear on its programme. Several of these will be of interest to physicists and others. Thus Prof. S. Brodetsky will read a paper on "The Einstein Field-Theory," and Prof. A. C. Dixon will discuss integral equations, a subject which is rapidly becoming important in physical investigations. There will also be a paper on modern Babbage calculating machines by Dr. L. J. Comrie.

CHEMISTRY.

For his presidential address to Section B (Chemistry) Prof. G. T. Morgan, director of chemical research in the Department of Scientific and Industrial Research, has chosen the title "A State Experiment in Chemical Research." He will discuss the development of the Chemical Research Laboratory at Teddington since its beginning five years ago. His account of the investigations now in progress at that institution will be illustrated by an exhibit of preparations, apparatus, and models of chemical plant.

On Friday, Sept. 5, a discussion will be held on the present position of the British dyestuff industry—a topic which is particularly opportune in view of the impending lapse of the Dyestuffs (Import Regulations) Act in January 1931. In opening the discussion, Prof. A. G. Green will review the development of the British industry since 1901, when he gave an account of the position at the Glasgow meeting of the Association. Subsequent speakers will be Prof. J. F. Thorpe, president of the Chemical Society and a member of the Dyestuffs Industry Development Committee, Sir William Pope, and the following members of the Dyestuffs Industry Development Committee: Messrs. C. J. T. Cronshaw, G. Holden, J. Morton, and Major L. B. Holliday. Mr. W. J. U. Woolcock will sum up the debate.

Another important discussion will be opened on Monday, Sept. 8, by Dr. F. L. Pyman, on "Chemo-

therapy". This is the first time that this important subject has been discussed, and those taking part include Prof. G. Barger, Prof. R. Robinson, Dr. A. J. Ewins, Dr. T. A. Henry, Dr. H. King, Prof. G. T. Morgan, and Prof. C. S. Gibson (Recorder).

Amongst other important individual communications are those by Prof. M. W. Travers, and Prof. N. Semenoff, of Leningrad. Prof. Travers will give an account of "New Experimental Methods for the Study of Gas Reactions". Although Prof. Semenoff is unable to attend the meeting, his paper on "The Initiation of Combustion" will be summarised by Prof. W. E. Garner, and it is hoped that this will lead to a discussion in which Prof. Garner and Mr. A. C. G. Egerton will take part.

GEOLOGY.

Prof. O. T. Jones's presidential address to Section C (Geology) will deal with "Some Episodes in the Geological History of the Bristol Channel Region", a subject that seems particularly appropriate to the place of meeting. Two of the items on the agenda arise out of the meeting in South Africa last year. Dr. G. Slater spent the greater part of his stay there in studying the earlier glacial deposits and will read a paper entitled "The Dwyka Tillite of Griqualand West". The question of the correlation of past pluvial and glacial periods is to be discussed jointly by Sections C, E, and H (geology, geography, and anthropology). It is perhaps doubtful if any geologist thinks this is possible at present, but a summation of the present position and a consideration of the difficulties in view may indicate lines for future work.

Perhaps of greater interest will be the sectional discussion on "The Validity of the Permian as a System". Since Murchison in 1841 divided the New Red Rocks into two systems, the Permian and the Trias, the status of the former division has been the subject of much controversy. Whilst abroad much greater thicknesses of rocks have been placed in that division, in England the system has been whittled down by the placing of the lower beds in the Carboniferous System. No doubt the exceptional British position will be thoroughly explored, and it is hoped that the wider aspects of the problem will receive due attention.

Both Upper and Lower Carboniferous Rocks come under review, for Prof. G. Delépine (of Lille) will describe "The Dinantian Zones of Goniatites in North France and Belgium", and Dr. D. A. Wray will discuss the sequence of non-marine lamellibranchs in the Upper Carboniferous of Yorkshire. Two papers on classification by Dr. A. E. Trueman and W. S. Bisat may prove somewhat controversial.

Of wide general interest should be Prof. J. W. Gregory's account of the recent cable fractures due to an earthquake in the Western Atlantic. The first description of a liverwort-like plant from the Lower Downtonian of the Llandovery District will be made by Dr. A. Heard and Mr. J. F. Jones.

GEOGRAPHY.

The president of Section E (Geography) will be Prof. P. M. Roxby, of the University of Liverpool, whose address will be devoted to a review of "The Scope and Aims of Human Geography". Since one of the most fruitful local applications of the work of modern human geographers has been in connexion with the development of regional survey and regional planning, it is opportune that this aspect should receive particular attention at this meeting. Thus the main principles of the South-West Lancashire regional plan are to be analysed by Mr. Peirson Frank, while Prof. P. Abercrombie will deal with the problems of satellite towns. A discussion on these papers will be opened by Dr. Vaughan Cornish.

Various aspects of the Bristol region will be dealt with by Mr. W. W. Jervis and others, while the contribution made by Bristol to English exploration will be reviewed by Col. E. W. Lennard.

Problems concerning past changes in climate will occupy an important place in the work of the Section at the Bristol meeting, since in addition to the joint discussion with Sections C and H on the relations between past pluvial and glacial periods, the Section of Geography is to have papers dealing with climatic changes in historic times in parts of both the Old World and the New. The former will be dealt with by Dr. C. E. P. Brooks and the latter by Prof. A. E. Douglass (of the University of Arizona), who will be the foreign guest of the Section.

One morning is being devoted to papers dealing with various parts of Africa, and another will be occupied by a series of detailed physical and economic studies of parts of Great Britain.

ENGINEERING.

The subjects to be dealt with by Section G (Engineering) are somewhat broad in their scope. The president, Sir Ernest Moir, Bt., an authority on tunnelling and other operations at great depth, will speak on that subject in his address. Section G will afterwards join with Section I (Physiology) to discuss the physiological effects of the high pressures to which those working in these operations are subjected. This discussion is important, since these effects set a limit to what may be undertaken.

Of more general interest, perhaps, are three papers on "The Trend of Airship Development" to be given respectively by Col. V. C. Richmond, the designer of *R101*; Mr. B. N. Wallis, of *R100*; and Herr Direktor Doerr, of the Zeppelin Company. These papers will be followed by films illustrating the construction and operation of the British and German airships.

The question of the economical production of power, so important to us as a nation, is to be considered from various points of view. Mr. George A. Orrok, of New York, on "High Pressure and Temperature Steam"; Sir Henry Fowler, on "Fuel Consumption in Locomotive Practice";

and Messrs. A. L. Stanton and T. Stevens, on the "Distribution of Electrical Power", will lead the discussion.

The importance of Bristol as a centre of the aircraft industry is reflected in the paper on "Recent Developments in Air-cooled Aero-engines" by Mr. C. F. Abell, of the Bristol Aeroplane Co. Messrs. T. F. Hurley and R. Cook, of H.M. Fuel Research Station, Greenwich, will describe some of their researches on petrol engines; while Dr. S. J. Davies and Mr. Edmund Giffen will review the present position of the high-speed heavy-oil engine.

Section G will conclude the meeting with a discussion on steel for structural purposes and its standardisation. The degree of standardisation of steel sections can naturally exert a great influence upon costs of production, and the subject is to be treated from the points of view of the consulting engineer, the manufacturer, and the technician by Mr. J. S. Wilson, Mr. J. S. Lewis, and Prof. C. Bath respectively. Reports of the special research committees will also be presented.

ANTHROPOLOGY.

Anthropology (Section H) at the Bristol meeting will be under the chairmanship of Dr. H. S. Harrison, whose work has made the Horniman Museum a centre of study of the evolution of the arts and crafts. His address will appropriately be followed by a discussion of the project of a National Folk Museum, in which Dr. R. E. Mortimer Wheeler and Prof. J. L. Myres will take part, while the officers of the interesting museum of the City of Norwich will give an account of their valuable work. On Tuesday, Sept. 9, geologists, meteorologists, archæologists, and geographers will gather to discuss the sequence of phases of the Pleistocene ice age. Agassiz gave an early account of views on this subject at the British Association in 1840, while, about the end of that century, James Geikie in Britain and Penck and Brückner in Central Europe were trying to correlate phases in different regions. This difficult task is entering on a new phase in which study of maritime and river terraces is being brought into the question and dynamic considerations concerning growth and decline of ice sheets are playing an increasing part. The field work of Misses Caton-Thompson and Gardner in the Faiyum, of Messrs. Sandford and Arkell in Egypt, Leakey and Solomon in Kenya, Cammiade in South India, and Armstrong at Bambata in Rhodesia, will be brought into the scheme, and the discussion is likely to make a definite advance.

The University and city of Bristol have played a great part in anthropological studies, and a memorial lecture by Sir Arthur Keith will offer a tribute to the pioneer, Dr. John Beddoe, the chair being taken by Sir Evan Jones, an old student of Bristol and of Dr. Beddoe. The memory of Dr. Czaplička, at one time lecturer at Bristol, is cherished in anthropological circles, and the Spelæological Society of the University has made itself a place in the history of the science. It is, therefore, specially interesting that an unusual number of papers on local archæology and anthropology are being presented to the section after an introductory study of the area by Mrs. D. P. Dobson. The interesting discussion of the ruins at Zimbabwe in Rhodesia, which was a main feature of last year's meeting, will be continued by Miss Caton-Thompson, with Dr. Randall MacIver in the chair, an appropriate choice, as his book on medieval Rhodesia twenty years ago first made a serious attempt to combat fanciful speculations on this subject.

PHYSIOLOGY.

In Section I (Physiology) the work of the meeting will open with the presidential address by Prof. H. S. Raper on "The Synthetic Activities of the Cell". It is expected that this address will be characterised by vigorous thought and that it will provide material for lively expressions of opinion in the discussion to which the president has consented. Among the remaining items, in all probability the foremost in the breadth of its appeal is the joint discussion with Section G (Engineering), somewhat heavily entitled "Air Pressure Variations encountered in Engineering Works, and their Physiological Effects". The speakers from Section I will be (1) Capt. G. C. C. Damant, R.N., qualified not only by reason of his work with J. S. Haldane and Boycott, and his share in the preparation of the Admiralty tables regulating the decompression of deep-sea divers, but also by a personal experience of such work lasting over twenty years and including the recovery of £5,000,000 of bullion sunk in the *Laurentic*, and (2) Sir Leonard Hill, whose experience of air pressure and movement effects on the physiological side is well known and whose katathermometers (and their modifications) have proved of enormous value in the accurate recording of conditions calculated to promote the comfort of workers in unusual surroundings.

The remainder of the programme includes papers covering a very wide range. On one side, the section has a contribution from Dr. F. W. Edridge-Green of the Board of Trade, on the detection of certain forms of colour-blindness especially important in the mercantile marine and a discussion with Section J (Psychology) on primary colours which, one fears, is likely to prove interesting rather than conclusive. On another part of the wide field over which this section extends, Prof. Ruggles Gates is speaking on "The Blood Groups and their Inheritance". Again, Prof. A. Stanley Kent, well known for his discovery of the auriculo-ventricular bundle, is returning to the laboratory which he designed to communicate some of his hitherto unpublished work.

PSYCHOLOGY.

Section J (Psychology) this year meets under the presidency of Prof. C. W. Valentine, who in his presidential address will review the present position of child psychology. The proceedings will open with an intra-sectional discussion on "The Psychology of Adolescence". A joint discussion

has also been arranged with Section I (Physiology) on the question, "In what Sense can we Speak of Primary Colours?" The various branches of psychology are well represented, experimental perhaps more strongly than usual. A visit has been arranged to Stoke Park Colony, where the director of medical services, Dr. R. J. A. Berry, will give a demonstration of scientific and clinical methods of diagnosis of mental deficiency and will discuss their applicability to child guidance and normal children.

BOTANY.

Dr. A. W. Hill, of the Royal Botanic Gardens, Kew, is president of Section K (Botany) of the Association for the Bristol meeting. The emphasis at present being laid upon original investigation in mycology and plant physiology is reflected in Section K by the preponderance of papers dealing with these aspects of botany, Monday morning being devoted to the former and Tuesday morning to the latter.

A joint discussion (with Section M) on "Mineral Nutrition in Plants" will occupy the major portion of Friday morning. The various aspects of the subject dealt with during the discussion will be summarised by Sir John Russell. An excursion to Long Ashton to study material illustrating some features of the problem will be made during the afternoon.

Among the distinguished foreign botanists proposing to attend are Prof. F. A. F. C. Went, of Utrecht, who is to read a paper on "Wegener's Theory and the Distribution of the Podostemaceae"; Dr. W. V. J. Osterhout, of the Rockefeller Institute, who is to contribute to the discussion on mineral nutrition; and Prof. W. Goodspeed, of Berkeley, Cal., who is outlining the results of his experiments with X-rays and radium on the species of the genus *Nicotiana*—a choice of subject which should have a particular appeal to the citizens of Bristol.

A number of attractive excursions have been arranged by local botanists, these including a visit to Mr. C. Hiatt Baker's garden at Almondesbury, and to the Somerset peat moors.

EDUCATIONAL SCIENCE.

The president of Section L (Educational Science) is the Right Hon. Lord Eustace Percy, whose presidential address will be entitled "A Policy of Higher Education". At the opening session of the section on Thursday, Sept. 4, papers will be given on "The Pre-School Child", by Miss Margaret Drummond (representing the Nursery School Association), Dr. J. A. Hadfield, and Dr. W. E. Blatz (Director of St. George's School of Child Study, Toronto).

Almost all one session will be devoted to "The Curricula of Central Modern and Senior Schools". Mr. W. A. Brockington will open with a general survey; Mr. J. A. White, Mr. H. T. Morgan, and Miss V. E. Carr Gordon will follow with papers dealing with the subject from the selective central school, the non-selective schools, and the modern girls' school points of view respectively. An interesting discussion will no doubt follow. The session will conclude with reports from sub-committees of the section dealing with training for overseas, the production and distribution of educational and documentary films, and the teaching of general science in schools, with special reference to the teaching of biology.

Another session will deal with formal training and disciplinary values in education. Dr. C. W. Kimmins will present the report of a sub-committee on formal training, and Sir Percy Nunn will read the first paper on "Disciplinary Value in Education", and will speak particularly with reference to "The Conception of Mental Discipline". Miss H. M. Wodehouse and Prof. F. A. Cavanagh will follow with papers on "Discernment of Disciplinary Values apart from Experiment" and "Some Further Practical Considerations". A final paper will be read by Dr. W. G. Sleight, and the discussion will be opened by Sir Richard Gregory.

For the final session the subject will be English and foreign ideas on method of education in relation to industry and commerce. Mr. Henderson Pringle and Sir Francis Goodenough are to deal with the subject mainly with reference to commerce; Dr. A. W. Richardson and Miss E. Webb Samuel will give papers dealing with the industrial aspect, and Mr. A. Abbott will conclude with a general paper on the whole question.

Afternoon visits to the local schools and the new Hospital School for Cripples at Winford are being arranged, and also a full day motor trip for the Saturday, during which Dauntsey School will be visited.

News and Views.

VERY hearty congratulations are extended to Sir Howard Grubb, who celebrates his eighty-sixth birthday on Monday next, having been born on July 28, 1844. Sir Howard was educated privately and at Trinity College, Dublin. In most parts of the world where observatories exist one may be sure that he has had a leading and expert part in the preparation of their equipment of mirrors, objectives, and all the varied apparatus and machinery of the modern astronomical observatory. Particularly is this the case as regards many of the great astronomical observatories of America; here his resourceful ingenuity has long been acclaimed. He has published many memoirs, chiefly through the medium of the Royal Dublin Society—among the earliest, "The Great Melbourne Telescope" (1870) and "On Clocks for Equatorial Telescopes" (1875). In 1896 he read a paper at the Royal Institution on "The Development of the Astronomical Telescope". In 1881 Sir Howard was the recipient of the Cunningham gold medal of the Royal Irish Academy, in recognition of work in the service of astronomers; in 1912 he received the Boyle medal of the Royal Dublin Society, awarded for scientific labours of outstanding merit carried out by Irishmen or in Ireland. Holding the honorary degree of master of engineering in the University of Dublin,

Sir Howard is also an honorary member of the Institution of Civil Engineers of Ireland. He was elected into the fellowship of the Royal Society of London so long ago as 1883.

DR. HERBERT LEVINSTEIN went fairly to the root of things in his presidential address to the Society of Chemical Industry delivered at Birmingham on July 15. "How we govern ourselves," he said, "how we arrange the exchange of our labour for goods or services, how we arrange our quarrels and our hates, social, racial, or international, all are merging into or depend on the greater problem of how we shall make the earth supply us with what we must have; how we can make the sun and the air do the maximum for us. This we may regard as one of the two great tasks of science. . . . The other problem of science is how to decrease human suffering by the conquest of disease." Hence the title of his address, "But an Apprentice in Nature's Workshop", and his remark that Aristotle's elements—earth, air, fire, and water are the real raw materials of our organic chemical industries; hence also his statement that a striking weakness of Great Britain to-day as a manufacturing country is its dependence on coal as a source of power. We reckon wealth in terms of our store of fossils, but the age of coal is passing, and Dr. Levinstein suspects that the age of coal will take up but little space when the history of the world is written a few generations hence. "It will have lasted, when it is over, for a shorter period than the Moorish occupation of Spain." Other countries are developing the use of water power; we have little, but the problem of finding sources of energy alternative to a diminishing store of fossilised energy is none the less, rather the more, urgent.

AN industrial nation must have cheap power; although the exhaustion of our coal supplies will concern our descendants more acutely than ourselves, we of the present generation are faced with the alarming fact that coal is now no longer the cheapest source of power, and consequently it is no longer suitable for the new and large, cheap power industries. One such industry, that which produces aluminium, possesses the only outstanding hydro-electric installation in Great Britain; this will eventually represent about 840,000 tons of coal annually. We must therefore look for some other source of power. Politics must of necessity enter into the examination of such questions as are discussed by Dr. Levinstein. They can scarcely be considered along traditional lines, for tradition is a poor weapon with which to slay new and unmistakably fiery dragons. Familiar points of view may indeed prove sufficiently well placed to envisage the new domain of industry, but probably they will not, and the whole political side of the matter will have to be examined anew and 'without prejudice'. It is therefore only just that we should refer briefly to some considerations which Dr. Levinstein lays before our legislators.

THE business of Great Britain, as seen by the 'Manchester school' of economists, is to import raw material and food and to export manufactures; the main principle is to buy in the cheapest and sell in the dearest market. This, said Dr. Levinstein, is the "principle of the cheapjack"; to buy in the most trustworthy and sell in the most permanent market is a better maxim. He would therefore buy food and timber from those who buy our manufactures. There is at present a world over-production of manufactured articles which is likely to be permanent, whilst the over-production of food and wood is certainly temporary; when it passes, the opportunity for making arrangements for mutual interest between Great Britain and those sparsely populated nations which own wide areas of food and forest lands may pass with it. Further, Dr. Levinstein stresses the fundamental importance of the proper utilisation of the land in a densely populated country where land is relatively scarce. Let us decide, he urges, what proportion we should have under grass and then ensure that every acre, whether grassland or arable land, is compelled to yield the maximum of nourishment for the people. By the application to pasture of intensive methods, seventy million pounds could be added to the annual value of our milk and meat production; this is more than double the value of imported American cotton, and its magnitude indicates both that the grass-manufacturing industry is of national proportions, and that our present lack of a consistent agricultural policy demands attention.

MANUFACTURERS of chemical products in Great Britain have shown that they are able not only to produce efficiently the numerous chemical materials demanded in every avenue of modern life, but also to display their goods attractively, to stimulate interest and inquiry into their fields of activity, and to organise effective means for the interchange of opinion and the promotion of common interests. Speaking at the fourteenth annual general meeting of the Association of British Chemical Manufacturers, the chairman, Dr. G. C. Clayton, said that as regards chemical exhibitions Great Britain is far ahead of any other country. In none of the big foreign fairs is there a chemical exhibit comparable in magnitude, variety, or interest with that at the British Industries Fair. It is evident, therefore, that the principle that progress must be built on knowledge—a principle lying at the very foundation of the chemical, as of every other, industry—has been applied in the selling branch as well as in the manufacturing branch; the policy is wise and necessary, and should go far in maintaining and advancing the position which British scientific and commercial men have together won for a young, but vital, industry. At the same meeting, Dr. Clayton referred to agreements with the corresponding French and German associations to collaborate in work having in view the greater safety of workpeople. The study of risks of fire and explosion has already been completed, and the results of this inquiry will shortly be submitted to members for their information and criticism. It is satisfactory to find that it has been agreed to regard safety in industry as a matter on which there shall be the fullest and freest exchange of information, subject only to the limitations imposed by the need for safeguarding confidential details of methods of manufacture. Dr. Clayton included in his

address an expression of sympathy with the proposal for the establishment of Chemistry House; the ultimate industrial advantage is, he said, likely to be so great that everyone should do what he can to further the success of the scheme.

AT a recent meeting of the trustees of the Beit Memorial Fellowships for Medical Research, Sir James K. Fowler, trustee and honorary secretary, presented the annual report, reviewing the work of the twenty years of the existence of the fund. The Beit Fellowships were founded in 1909 by means of a gift of £230,000 by Sir Otto Beit. The total number of those who have held fellowships to date is 138, a considerable number of whom now hold or have held important posts on the scientific staffs of universities, colleges, and institutes. It is not possible to review the researches which have been carried out by Beit Memorial fellows, but those of Sir Thomas Lewis on the heart and of Prof. Edward Mellanby on rickets have been of outstanding importance. In 1927 a senior fellowship, value £1000 per annum, for research in tropical medicine was created and Dr. Edward Hindle appointed. His work on yellow fever has yielded important results. A vaccine has been prepared from the organs of certain monkeys infected with yellow fever which gives protection to other animals of the same species against a dose of virus a million times as great as that which is fatal to the unprotected. It has also been shown that Europeans may suffer from a mild disease scarcely recognisable as yellow fever, and if this is also true of natives, this may be the means by which the continued existence of the disease is maintained in endemic areas in the intervals between epidemics.

THE following elections have been made to Beit Memorial Fellowships for Medical Research, the proposed subject of the research to be undertaken by Junior Fellows and the place where it is to be carried out being given in brackets: *Senior Fellowship* (value £700 p.a.), Mr. R. J. Lythgoe. *Fourth Year Fellowships* (value £500 p.a.), Mr. P. Eggleton and Dr. F. R. Winton. *Junior Fellowships* (value £400 p.a.), Dr. F. H. Smirk (to study the functional pathology and physiology of diuresis from a biochemical point of view, and to study the functional pathology of plethoras, anæmias, and œdemas—Medical Unit of University College Hospital, London); Dr. G. R. Cameron (to complete work on the histological identification of calcium salts in pathological deposits and to commence study of inflammation in invertebrates—Graham Laboratory, Department of Pathology, University College Hospital School); Mr. J. McMichael (to continue present studies on the interrelationships of liver and splenic disease, mainly by clinical and pathological methods and animal experiments—Department of Medicine, University of Aberdeen); Dr. R. P. Cook (to study bacterial metabolism and its relation to the specific action between host and bacterial parasite—Sir William Dunn Institute of Biochemistry, Cambridge); Mr. N. U. Meldrum (to study the so-called reversible denaturation of hæmaglobin—Sir William Dunn Institute of Biochemistry, University of Cambridge); Mr. D. R. P. Murray (to make a comparison of the two types of proteolytic enzymes characteristic of the tissues and organs and of the digestive tract—Sir William Dunn Institute of Biochemistry, Cambridge); Mr. G. N. Myers (to study the curative action of digitalis, its glucosides, and allies, in general toxæmia and in conditions of shock—Pharmacological Laboratory, Cambridge); Mr. C. A. Ashford (for studies on the (*a*) metabolism of nervous tissue; and (*b*) mode of action of vitamin D with special reference to hyper-vitaminosis D—Sir William Dunn Institute of Biochemistry, Cambridge).

THE valuable work which has already been accomplished in Great Britain by the various research associations is well known to workers in pure science and technology. The wide dissemination of the results of their researches and the task of securing adequate appreciation of those results amongst the ranks of industrial workers are, however, matters of considerable difficulty. The British Cotton Industry Research Association attempted in part to meet those points some two years ago by the publication of a report on research in the cotton industry, which gave an account, as free from scientific terms as possible, of the main topics of the published research work of that Association. The British Research Association for the Woollen and Worsted Industries, in its recent publication, "Scientific Aid for the Wool Industries", has supplied a similar summary which should prove valuable to workers in the many branches of the woollen and worsted industries. Reference is made in the report to fundamental researches which are in progress, particularly on the physical, chemical, and biological sides. The textile technologist will appreciate the attempt which has been made to improve existing methods of testing. In this connexion the development of methods for the reeling of yarn, for the testing of yarn levelness, and for the autographic recording of strength and elasticity, deserve special mention. The report offers abundant evidence of the progress of the Association. Its success in its relationship with industry may be judged by the fact that a scheme for the support of the Association by means of a voluntary levy upon imported wool has recently been conditionally adopted by the industry.

WE are glad to learn that, after delay since August 1928, the Cultural Society of Peking and the Government of Nanking have jointly given permission for the renewal of Central Asiatic expeditions of the American Museum of Natural History. Dr. Roy Andrews is now in the field north-east of Kalgan, with a very strong party, including Messrs. Granger, Thomson, and Young of the American Museum staff, Père Teilhard de Chardin as associate palæontologist, two Chinese zoologists and palæontologists trained by Dr. Abel of Vienna, Dr. C. C. Young, and Dr. H. Chang. Lieut. W. G. Wyman, U.S.A., accompanies the party as topographer The present survey is to the eastward of the Kalgan-Urga Trail where important Pliocene discoveries were made during the 1928 expedition, and the season's work will be chiefly in Pliocene horizons not represented in previous explorations west of the Kalgan-Urga Trail. Dr. Andrews' volume on the

narrative of the Expedition, Vol. I of the quarto series, is nearly ready for the press; Dr. Amadeus Grabau's volume entitled "The Permian of Mongolia" is now in press.

In a recent issue we published a summary of, and commented upon, Sir Arthur Keith's lectures on recent discoveries of early man and their bearing upon our knowledge of his origin, development, and distribution (see Nature, June 21, p. 935). How these discoveries have stimulated fresh interest in the discussion of man's place of origin may be gathered from an article by Prof. Elliot Smith which appears in the June issue of *Scientia*. As is well known, Charles Darwin in 1871 suggested that the survival in Africa of the two great apes most nearly allied to man pointed to that continent as the dwelling-place of our early progenitors. Many authorities have since taken the same view. On the other hand, the discovery of fossil apes in the Himalayas and of *Pithecanthropus* in Java has been held to point to Asia as the probable home of the human family. The evidence is reviewed, and carefully weighed, by Prof. Elliot Smith in his article. Notwithstanding the occurrence of a fossil ape in southern France, and setting aside the view of Schoetensack in favour of Australia and Ameghino's claim for South America owing to the absence in each of any possible ancestor of man, he concludes that the balance of probability is in favour of Africa. In arriving at this view he attaches considerable weight to the evidence afforded by the Taungs skull, now determined to be of Lower Pliocene age. He holds that while the Taungs skull cannot be mistaken for the gorilla or chimpanzee, and in the absence of prominent eyebrow ridges and in its upright forehead it resembles the orang, it affords definite though slight indications of the beginning of the process of refinement of the features that is an essential part of the transformation of the ape into a human being.

In October next a pageant entitled "Heart of Empire" will be held at the Royal Albert Hall. The date opportunely coincides with the meeting of the Imperial Conference which is to be held in London during that month. The pageant is to be taken from the book "Hyde Park: its History and Romance" by Mrs. Alec Tweedie, of which a new and abridged edition recently published is noticed in another column. It will last from Oct. 13 to 25 inclusive, and the proceeds will be given to charities. Each evening will have a special character· Oct. 14 the Lord Mayor, Oct. 15 Canada, Oct. 16 Australia, and so forth, the last evening being given to the United Services. It is gratifying to note that what may be called the imperial function of science is not to be overlooked, and one night, that of Oct. 22, is to be devoted to learned societies. Among the list of patrons, which includes the Maharajah of Kapurthala, the Dowager Maharanee of Cooch Behar, the Maharajah of Burdwan, the Duke of Sutherland, the Marquis of Londonderry, the Marquis of Aberdeen, Lord Jellicoe, Lord Meston, Lord Irwin, Viceroy of India, and a distinguished array of ministers, ex-ministers, and administrators, are also a number of prominent men of science. Among these are Sir John Rose Bradford, president of the Royal College of Physicians; Sir William Bragg, director of the Royal Institution; Sir Charles Close, president of the Royal Geographical Society; Sir Frank Dyson, Astronomer-Royal; Sir Arthur Keith; Sir Ronald Ross; Sir Ernest Rutherford, president of the Royal Society; and Prof. J. F. Thorpe, president of the Chemical Society. The organisers of the conference are to be congratulated on their far-seeing policy, which will bring home to a wide public the vital interest of science in, and its close connexion with, the problems of a world-wide empire such as ours.

Mr. J. L. Baird has recently made further progress in perfecting the applications of television for theatrical purposes. We see from the *Times* that a demonstration of this new art will form part of the programme of the London Coliseum in the week beginning July 28 and onwards. A disadvantage of the home television sets which are now on the market and receive broadcast television at certain hours of the day is the small size of the televised images. This makes it possible for only two or three people to see the screen properly. In the new apparatus for use in a theatre, the receiving screen is divided into 2100 elements. Each element consists of a cubicle which contains a tiny metal filament lamp, the front of the cubicle being covered with ground glass. The lamps are in circuit with bars on a large commutator. As the commutator revolves, each of the lamps is switched on in succession. The whole of the 2100 lamps are switched on and off in one-twelfth of a second. When operating, the incoming television signal is first of all amplified. The amplified current then flows through the revolving commutator. The current is strong at a bright part of the picture and weak at a dark part, and the picture is built up of a mosaic of bright and dark lamps. The lamps are not instantaneous in their action, and in this respect they differ from those used in other television devices. Great brilliancy, however, is attained by this means, and the flickering is much reduced. Experiments have been made at the Baird laboratories on the transmission of images showing considerable detail. It seems quite feasible to broadcast these pictures to distant cinemas by means of land lines.

A Civic Week lecture on "Science and the Fishing Industry", delivered at the University College, Hull, on Oct. 16, 1929, by Prof. A. C. Hardy, has been recently published as a pamphlet by Messrs. A. Brown and Sons, Ltd., Hull, price 6*d*. Prof. Hardy, who was chief zoologist to the *Discovery* expedition, discusses at some length the bearing of marine biological research upon the problems which confront the fishing industry. The men of science, he points out, by patiently investigating the many factors, some known, many yet unknown, which influence marine life, are gradually piecing together the story of what is going on below the surface of the sea. The work is laborious, disappointments are many, and progress is slow. Nevertheless, much has already been done, and last year,

for the first time in history, it became possible to forecast the prospects of certain fisheries. This is a great achievement, and Prof. Hardy is confident that, with more knowledge, this work can be extended and perfected so as to be of immense practical value. To bring immediate financial benefit to the trade, however, is not the only function of marine investigation. Much of its efforts must of necessity be directed towards the accumulation of knowledge which will result in no immediate gain to the industry, but is absolutely necessary as a basis for intelligent legislation in future, should occasion demand it. A strong plea is made for more co-operation between science and the industry—between the research worker and the fisherman. Each has much to learn from the other. Stress is also laid upon the paucity of financial support for scientific research. The trade, says Prof. Hardy, pays but a few hundred pounds a year to research institutions, and that more as a kind of charity than as an economic investment. To be of real benefit, research must be carried out on a scale bearing a reasonable relation to the magnitude of the industry. For this to be done, ample funds are essential.

AT the recent World Power Conference, Dr. Oskar Oliven gave a remarkable address on a "European Grid Power System". He pointed out the gradual growth of small power plants to huge power stations, the voltages of which were ever increasing. Interconnexions were being made between these stations, resulting in important economies being effected. Exchange of energy and compensation of load were now taking place over political frontiers, and the question had now become one which had to be considered by the whole of Europe. The problem could be solved if the visible and invisible boundaries which separated nations could be freely opened to the passage of electric energy for their mutual benefit. The idea of the peaceful co-operation of nations was gaining ground. The approximate length of the European super power system he suggested was 6000 miles. It included Calais, Rome, Constantinople, and Oslo. Britain and the northern part of Russia are left out for economical reasons. He assumes that capital can be obtained at 4½ per cent interest, and that the total cost would be about £100,000,000. He calculated that the average cost per unit would be reduced to about the fifth of a penny. He proposes to use a supply pressure of 400 kilovolts. There are now no technical difficulties in the way. He considers that the utilisation and application of electricity has become one of the strongest factors in international economy. A map of the proposed European grid is published in the *Electrician* for July 4.

AT the ninth annual general meeting of the Empire Cotton Growing Corporation, held in Manchester, with Lord Derby in the chair, on May 29, his son, Lord Stanley, made some very interesting comments upon the possibilities of agricultural development in India as affected by the coming completion of the Sukkar Barrage on the River Indus. With the completion of this barrage, which is anticipated for 1932, it is estimated that the irrigated area in India will increase from 2,035,000 acres to 5,394,000 acres, and much of the new land is thought to be of very good quality, capable of producing a better class of cotton than is at present grown in any cotton district. Lord Stanley made two very important and suggestive criticisms in connexion with this vast scheme. He pointed out that if full use is to be made of this new area under irrigation, the advisory research services which must guide in technical matters should be created *now*; Lord Stanley is emphatic that progress should be speeded up in this direction. He also pointed out that it is essential that some large estates be created in the new irrigation area, with the necessary capital and equipment in men and materials to enable new methods of cultivation, adapted to the changed conditions, to receive a thorough trial. The small cultivator is too conservative and too poorly equipped to make the necessary trials of new methods, and unless some large estates are organised in good time, much time may be lost after irrigation commences in learning how to make full use of the new potential sources of agricultural fertility.

THE first report of the Museum of Science and Industry, Chicago, founded by Mr. Julius Rosenwald in 1926, covers the period July 1928 to December 1929, and is a record of very active progress which, if maintained, will place the Museum in the forefront of such institutions in the United States. The provision of a building is always a serious matter, but it appears that from the first the founder had in view the utilisation of the much-admired Fine Arts Building erected for the World's Fair in Jackson Park in 1893. It is more than doubtful whether it would not have been wiser to have had a new building. Facts go to show that the cost of reconditioning this old building is going to be as great as the cost of a new one without any corresponding advantages. The Director, Mr. Waldemar Kaempffert, was appointed in 1928, and he has studied the older institutions of the same kind in Europe, particularly the Deutsches Museum at Munich. It is evident that he has been strongly influenced by what he has seen and no radical departure from them appears to be in view. He is alive to the necessity of drawing up beforehand schemes of what ought to be shown, and he is avoiding the pitfalls of accepting objects not strictly within the scheme; he is obtaining, too, the co-operation of individuals and firms. In fact, the idea of the industrial museum at last seems to have gripped the American imagination. We wish the institution much and early success.

IN the annual report of the Geophysical Laboratory of the Carnegie Institution of Washington for 1928–29 (*Year Book* No. 28 of the Institution), the director (Dr. A. L. Day) describes two important scientific expeditions in which the laboratory has participated. The first was for the study of volcanoes in the Dutch East Indies, where many active volcanoes are found within a small area; Dr. Zies, who undertook this work, went provided with spectrographic apparatus for the investigation of volcanic flames. This part

of the programme was unsuccessful, but valuable experience was obtained which it is hoped to utilise later; and gases, incrustations, and lavas were collected which have provided interesting material for laboratory studies. The other expedition was a gravity-measuring cruise in a United States submarine, using the methods and apparatus of Dr. Vening Meinesz, who accompanied the expedition; the U.S. Navy and the National Academy of Science co-operated with the Geophysical Laboratory in this work. A cruise of 45 days was undertaken in October and November 1928, in the Gulf of Mexico and the Caribbean Sea. Measurements of gravity were made at 46 sea stations, as well as others in various harbours. It was found that isostatic compensation in the Mississipi Delta is practically complete, despite the deposition of nearly 12 billion tons of matter there each year. But anomalies indicate that the Nares Deep is a recent uncompensated geological feature in which there must be large shearing stresses (see NATURE, Mar. 23, 1929, p. 473).

THE University of Melbourne has recently issued in bound form several volumes of "Collected Papers from the Science Laboratories". Vol. 5 consists of separata that have appeared during the years 1910 1928 and come from the following departments: Anatomy, 9 papers; zoology, 19 papers; and veterinary science, 14 papers. The papers cover a wide range of subjects, and in all departments deal with matters not only of local interest or rather concerning local material, but also of a more general nature. The former group contains anatomical investigations of Tasmanian aboriginals and Melbourne criminals; a number of descriptions of new Australian invertebrates, parasitic and otherwise, and studies on the parasites and diseases of Australian cattle. The second group include anatomical studies of man and other mammals; investigations into the development of the fowl, and parasites and diseases of cattle not limited to Australia. Altogether the papers show a commendable recognition of the importance of research as an essential function of University activity. From the personal point of view we are glad to see the name of Baldwin Spencer as part author of one of the papers in the zoological section, as it is probably the last paper by one whose recent death has deprived the University of an outstanding personality.

THE Report of the Secretary of the Smithsonian Institution for 1929 records a year "gratifyingly and unexpectedly rich in progress". One of the most important ventures has been the addition to the research laboratories of a new department, the Division of Radiation and Organism, the object of which will be to investigate the relationship between radiation and the growth and health of plants and animals. During the year twenty-nine expeditions, fitted for anthropological, geological, biological, or astrophysical investigation, sought knowledge and materials in distant parts, from Alaska to China, Cuba, and Haiti. As material has flowed in publications have flowed out, including, in addition to the usual monographs and articles, four volumes of the 12-volume set entitled "Smithsonian Scientific Series". The National Zoological Park has obtained a new building for birds, believed to be the best for its purpose in the world, and provision has been made by Congress for a new reptile house equally well designed; and certainly not least, an extensive collection of paintings and art treasures, valued at several million dollars, has been given by Mr. John Gellatly to the Smithsonian for eventual exhibition in the National Gallery.

WITH reference to our remark (June 14, p. 901) on the lack of a serious policy for the encouragement of children in the national museums, Dr. G. H. Carpenter sends us an account of the school work conducted in the Manchester Museum. Five trained teachers specially appointed by the City Education Authority take five classes a day, and each class, paying a weekly visit, gets a systematic course of lessons, with the advantage of illustrative specimens and objects freely placed at the teachers' disposal. Such an arrangement is excellent; it is the best possible plan under the passive system where the museum allows the fullest use to be made of its treasures. Our notion was that, if the system of the Peabody Museum were adopted, the national museums by means of their own staffs—specially appointed for the purpose, of course, but responsible to the museum authority—would become active agents in spreading knowledge of their treasures inside and outside the museum. We look forward to a time when it will be recognised that education is as much the duty of a museum as is the care of specimens.

ETON COLLEGE has followed excellent precedents in having formed a Natural History Society, the threefold purpose of which is to observe and collect local plants and animals, to make and listen to lectures, and to keep a log-book of all observations. The first annual report (1930) records a creditable number of these original faunistic observations, which concentrate upon the stock lists of birds and Lepidoptera; but there are many little problems of local distribution and numbers, of life-habits, and seasonal changes, which the members could tackle with advantage to their own powers of observation and reasoning, and to the advance of scientific knowledge. There is evidence in the report of abundance of enthusiasm, and we wish the new Society a long life and a busy one.

IN the General Report of the Survey of India 1928–1929 one of the most notable achievements recorded is the completion of the survey of Chitral on the 1-inch and ½-inch scales. This was one of the most difficult pieces of work in the survey of India. Another achievement was the survey of about 800 miles of previously unexplored country in Bhutan by permission of the Bhutanese Durbar. A summary of topographical surveys shows that about forty-eight thousand square miles was surveyed during the year, an area rather in excess of the average of recent years. So steady is the progress of the work that rather more than half the total area of the Indian Empire has now been surveyed, mainly on a 1-inch scale, but in places

on a $\frac{1}{2}$-inch or $\frac{1}{4}$-inch scale. The report contains a key sheet to all maps of the survey of India.

THE North-West Territories Branch of Canada's Department of the Interior has issued a finely illustrated handbook entitled "The North-West Territories, 1930". This gives besides a general account of an area which embraces over a third of Canada, many valuable notes on the forests, other vegetation, and wild life. Particular attention is paid to the Eskimo, who, according to a census made in 1927, number little more than 7100. The Department of the Interior has also published a revised map of the North-West Territories on a scale of 60 miles to an inch. It has no orographical detail but there are a wealth of names and indications of all the police and trading posts and the position of the game preserves. From the Natural Resources Intelligence Service of the same department comes a finely illustrated volume on the province of New Brunswick with several maps and much statistical information. Copies can be obtained free of charge from the National Development Bureau, Ottawa.

ALTHOUGH the present buildings of the Mellon Institute of Industrial Research were completed only in 1915, for practically ten years the Institute has had a waiting list of companies with problems for investigation. A new building is therefore to be erected and work on it will start this year. In addition to providing a greatly increased number of laboratories, the new building will give more commodious quarters for the general departments. The present library contains 11,000 volumes; the new library is planned to accommodate 250,000 volumes. The present Department of Research in Pure Chemistry will be expanded and facilities for pure research in other branches of science will be provided. Much more elaborate chemical engineering laboratories are to be available, and the fellowships in each specific field of industrial research are to be grouped in suites of rooms so that they can best make use of general apparatus adapted to their needs. Certain rooms will be equipped for specialised phases of experimental technique, such as electrochemistry, spectroscopy, low-temperature studies, radiations, high-pressure experimentation, etc. Other special features to be included are a large lecture hall, a dining hall, an industrial fellowship museum, and an underground garage. The new laboratory will be seven stories high, with monolithic columns along all four sides, and approximately 300 feet by 400 feet. The laboratories are to face on interior courts, and additional laboratory suites can be constructed in the interior courts without interfering with the original laboratory units.

THE Messel medal of the Society of Chemical Industry was presented to Lord Brotherton of Wakefield during the forty-ninth annual meeting of the Society, for his services to chemical industry.

THE Minister of Agriculture and Fisheries, with the approval of the Army Council, has appointed Brigadier H. St. J. L. Winterbotham to be Director-General of the Ordnance Survey, in succession to Brigadier E. M. Jack, who retires on July 31 next. Brigadier Jack was president of Section E (Geography) of the British Association for the South Africa meeting last year.

A PROGRAMME has now been issued of the Southampton meeting of the Institute of Metals, to be held on Sept. 9-12. The proceedings will be opened on Sept. 9, when the ninth autumn lecture will be given by Prof. D. Hanson, on "The Use of Non-Ferrous Metals in the Aeronautical Industry". The mornings of Sept. 10 and 11 will be devoted to the reading and discussion of metallurgical papers, several of which are being contributed by distinguished metallurgists from abroad. Some attractive visits and excursions, including a trip to Cherbourg during the following week-end, have been arranged in connexion with the meeting.

A CONFERENCE on Soil Science Problems, to be opened by the Right Hon. W. G. A. Ormsby-Gore, will be held at the Rothamsted Experimental Station on Sept. 16-18 under the auspices of the Imperial Bureau of Soil Science. The discussions will cover soil analysis, surveys, field experimentation, and similar topics. The Conference will be the occasion of the annual visit of Empire agricultural officers.

A FURTHER step to encourage co-operative marketing in Great Britain is seen in the modification of the terms under which loans to marketing enterprises are issued. The Ministry of Agriculture's Advisory Committee on Co-operation and Credit has recommended that the initial period of remission of interest on a loan may be extended from two up to five years. Full particulars are published in Marketing Leaflet No. 19, which may be obtained post free from the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1.

A CORRESPONDENT has directed our attention to the fact that recently two tubes of anhydrous aluminium chloride supplied to a school laboratory exploded on opening. It should be kept in mind that these tubes frequently contain a considerable pressure of hydrogen chloride gas and are liable to burst if any attempt is made to open them with a file. The tubes are perhaps best opened by wrapping in a thick duster and softening the drawn out end with a blowpipe flame. When the rush of gas ceases, the tube may be cut open. We think it would be advisable for the dealers to attach some such information as a label on the tube, but in any case those teachers who are not aware of the danger would do well to take note of it and should never allow pupils to open such tubes.

AN International Illumination Congress will be held in Great Britain in 1931 under the auspices of the International Commission on Illumination (which succeeded the International Photometric Commission) and is being organised by the National Illumination Committee of Great Britain and the Illuminating Engineering Society. The first week of the Congress, Sept. 3-12, will consist of a tour starting from London and visiting Glasgow, Edinburgh, Sheffield, and Birmingham; technical sessions will be held at each city. The second part of the Congress, Sept. 13-19,

will be at Cambridge. The subjects for discussion include factory lighting, street lighting, museum lighting, laboratory technique, and so on. The countries represented by National Committees on the International Commission on Illumination include most of the European powers, Japan and the United States; the president (1927–31) is Mr. C. C. Paterson, honorary secretary Dr. J. W. T. Walsh, and central bureau the National Physical Laboratory, Teddington. The honorary general secretary of the 1931 Congress is Col. C. H. S. Evans, c/o Illuminating Engineering Society, 32 Victoria Street, London, S.W.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: Assistant entomologists under the Division of Economic Entomology of the Australian Commonwealth Council for Scientific and Industrial Research, for research work on buffalo fly and blowfly problems—F. L. McDougall, Australia House, Strand, W.C.2 (July 30). A lecturer and demonstrator in plant pathology at the Swanley Horticultural College—The Principal, Horticultural College, Swanley, Kent (July 30). An evening teacher in electrical engineering at Goldsmiths' College—The Warden, Goldsmiths' College, New Cross, S.E.14 (Aug. 2). A lecturer in charge of the mining department of the Walker Technical College, Hartshill, Wellington, Shropshire—The Principal, Walker Technical College, Hartshill, Wellington, Shropshire (Aug. 9). A curator of the natural history department of the Kelvingrove Art Galleries and Museums, Glasgow—The Town Clerk, City Chambers, Glasgow (Aug. 15). A cotton classer, a cotton entomologist, and an assistant pathologist, each under the Department of Agriculture and Stock, Brisbane—The Official Secretary, Queensland Government Offices, 409 Strand, W.C.2 (Aug. 20). A lecturer in chemistry at the Leicester College of Technology—The Registrar, Colleges of Art and Technology, Leicester (Aug. 25). A demonstrator in chemistry in the University of Aberdeen—The Secretary, The University, Aberdeen (Aug. 30). An expert hydrobiologist for fisheries investigations in Turkey—The Expert-Adviser of Fisheries—Mr. E. C. Weberman—Beyoglu, Sira Servi 4, Istanbul, Turkey (Sept. 15). A George Herdman professor of geology in the University of Liverpool—The Registrar, The University, Liverpool (Sept. 30).

ERRATUM.—In NATURE for July 19, p. 109: Paragraph "The Planet Saturn", line 7, for 838,500 read 838,500,000.

Our Astronomical Column.

Recent Solar Activity.—During the last few months there has been a noticeable absence of large sunspots and a steady diminution each month since January in the average daily number of groups. Although the solar cycle is progressing towards minimum, the very active period (Nov. 1929–Jan. 1930) and the present one of decline (Mar.–June 1930) would seem to be merely one of the many 'ups and downs' shown by the sunspot curves of preceding cycles when plotted from means taken over periods of a month or of a solar synodic rotation. Unless the present cycle is abnormal, the minimum is to be anticipated about 1934. During the last fortnight there have been signs of a revival of activity. On July 13–14 two large prominences were seen at the sun's east limb, and they could be followed as dark absorption markings in hydrogen or calcium light as the sun's rotation brought them across the disc. The larger and more massive prominence, in latitude about 25° N., was seen with the spectroheliioscope at Greenwich on July 18 as a strongly defined marking nearly 6′ in length, although still somewhat foreshortened, and inclined about 30° to the sun's equator.

The Approaching Opposition of Eros.—Eros will be nearest to the earth at the end of January 1931, when its parallax will be 50·3″. Dr. H. Spencer Jones contributes a paper with useful hints to observers which is published in *Astr. Nach.* 5715.

The rapid motion of Eros makes short exposure times and rapid plates desirable. The relative advantages of guiding on Eros or on the stars are discussed. It is thought that a suitable plan may be to follow Eros in R.A., but allow it to trail in declination. It will be brighter than most of the comparison stars, and its light should be reduced by a rotating sector. No photographs should be used in which the conditions of seeing have not been constant, as this may involve an error in the effective mean time of mid-exposure.

The light of Eros is sometimes subject to rapid variations; this also may affect the mean time of mid-exposure. The times of beginning and end of exposure must be accurately noted, on account of the rapid motion.

One of the useful by-products of the campaign will be an improved mass of the moon. Photographs for this purpose should be taken at the times when the difference of the R.A. of Eros and the moon is near 0^h, 6^h, 12^h, 18^h. These photographs may be taken near the meridian, whereas those for parallax in R.A. are taken at large hour-angles.

It is recommended that stars of extreme colour (types *B* and *K*5 to *M*) should not be used as comparison stars. *Harvard Bulletin* No. 871 gives the spectral types of the primary reference stars that are not in the Henry Draper Catalogue.

Meteors connected with Comet 1930 *d* (Schwassmann-Wachmann).—It was noticed soon after the discovery of this comet that its orbit approached that of the earth fairly closely. A watch for possible meteors was kept at the Kwasan Observatory, Kyoto, Japan. *Bulletin* No. 172 of the Observatory reports that Mr. T. Miyasawa observed numerous meteors on May 21 and the following nights. Mr. S. Sibata has derived the following orbit for the meteors; the latest orbit for the comet, by Miss Hayford and Mr. Anderson, is given for comparison:

	Meteors.	Comet 1930 *d*.	
T	—	1930 June 14·21981 U.T.	
ω	212° 24′	192° 19′·4	1930·0
Ω	60 10	76 45·2	1930·0
i	18 50	17 17·9	1930·0
log q	9·965	0·004934	
Period	—	5·2668 years.	

Mr. H. E. Wood has pointed out that there is a general resemblance between the orbit of this comet and that of comet Pons-Winnecke, suggesting that the two comets may have had a common origin.

Research Items.

Melanesian Shell-Money.—In No. 1 of vol. 1 of the *Anthropological Series of the Publications of the Field Museum, Chicago*, Mr. Albert B. Lewis describes the Melanesian shell-money in the museum collections. Many different kinds of shell-money are in use in Melanesia, but each is confined to a small area, outside which it has little or no value. Usually it takes the form of small discs on varying lengths of string; but in some places, such as the central Solomons, large shell-rings were manufactured which had a high value. Tanga arm rings in New Zealand would each buy a wife or one or two pigs. In the Gazelle Peninsula, New Britain, the *dwarra* currency was strung on rattan which could be broken to any length to make change. The Duke of York Islands was an important centre for the manufacture of the broad-shell variety of money called *pele*. It was put up in short strings tied in bunches. Though it had a standard value it was not actually used as money, but was traded to New Ireland and New Britain. The chief centre of manufacture of shell-money was the small islands around New Ireland, and the great number of these islands must be held to account for the great number of varieties. The value depended on colour and workmanship, the most valuable being the small red discs. The most elaborate and valuable variety of New Ireland money was that known as 'pig money', which was used for the purchase of pigs for use in ceremonial. Its value was so great that only very wealthy people could acquire it. It has long disappeared from use. Shell disc money, though not so common as in New Ireland, was also in general use throughout the Solomons, Santa Cruz, Banks, Northern New Hebrides, and New Caledonia.

Urn-Burials in Alabama.—Among papers submitted to a Conference on Mid-Western Archæology held in St. Louis, U.S.A., in 1929, of which a report is issued as *Bull. No. 74* of the National Research Council, Washington, was an account of recent discoveries made along the Tallapoosa and Alabama Rivers by Mr. P. A. Brennan. Among them a large number of urn-burials were found. This custom is said to be an indication of Choctaw cultural influence. The Choctaw are said to have placed their dead on racks until the flesh had decayed before burying them. Articles associated with these burials indicate that they had a much higher cultural level than their descendants. Their pottery is of heavy earthenware, shell-tempered, glazed with charred grease, and sometimes the vessels are of a capacity of eight gallons. At Montgomery a cache of twelve urns, each covered with a bowl, all contained skeletons—adults, children, and babes. Several contained remains of more than one individual. The largest was 26 inches in diameter and the smallest 8 inches. Yet the latter contained the complete skeleton of a baby. The urns were close to the surface and the arrangement may have been intended to represent a constellation. A similar find made a few years ago consisted of nine urns arranged around a central urn. A vault-like placing had been attempted in a hole 25 feet in diameter which had been cut in red clay. Into this was poured quartzy gravel, periwinkle and mussel shells from the kitchen middens, and then ashes. After the vessels had been placed in position, they were surrounded with layers of gravel, shells and ashes, and then covered with clay. This was then hardened by fire. Interments in the earth and apparently contemporary accompanied them. Shell objects, though not numerous, are indications of a high civilisation, while the shell pictures, especially that of a figure with its protruding tongue transfixed by a sword, suggest contact with Mexico.

Economic Standing of Members of the Crow Family.—Having already discussed the food of the rook and jackdaw, Dr. Walter E. Collinge (*Jour. Ministry Agr.*, May 1930, p. 151) turns to four other members of the family, the carrion crow, the hooded crow, the magpie, and the jay, all of which have been condemned from one point of view or another. His conclusions do not support the almost universal views of game-preservers, and they are of great interest to a more important group of economic workers, the farmers. It was found that 36 per cent of the food of these birds was of direct benefit to the farmer and fruit-grower, since it consisted of injurious insects, mice and voles, slugs and snails. On the other hand, 18 per cent was injurious, but of this, half represented the destruction of the eggs and young of wood-pigeon, blackbird, gulls and ducks. Evidently any destruction of these 'crows' is prejudicial to the interests of the farming community. Even so far as game-preserving is concerned, Dr. Collinge finds that the injuries are not excessive, and thinks that they have been generally over-estimated.

Birds of Buru.—In 1921-22 L. J. Toxopeus made a collection of the birds of Buru, in the Moluccas, which has added considerably to the list of species and to our knowledge of the differentiation of races in that area. Stresemann in 1914 recorded 135 species from Buru; now H. C. Siebers brings the number to 167 (*Treubia*, vol. 7, suppl., May 1930). His work is of more than ordinary faunistic interest on account of its careful descriptions of racial characters, of the habits of some of the native birds, and of the detail with which the breeding areas have been worked out.

Coleoptera of Italy.—In *Memorie della Pont. Accademia delle Scienze Nuovi Lincei*, ser. 11, vol. 13, 1929, there is to be found an important contribution entitled "I coleotteri d' Italia", by Paolo Luigioni, S.O., which will interest coleopterists and students of insect distribution. This extensive compilation amounts to 1135 pages and consists of a catalogue of the beetles of Italy together with the literature dealing with them. The area embraced in this work includes continental Italy, and also Corsica, Sardinia, Sicily, and the Maltese Islands. Altogether 1169 genera and 9979 species of Coleoptera are enumerated as occurring in the area under consideration. In an appendix a number of additional species are listed provisionally owing to their identity being doubtful. As might be expected, the families most numerous in species are the Curculionidæ, Staphylinidæ, and Carabidæ, with 1610, 1595, and 1059 species respectively. As compared with the paucity of the British fauna, it is interesting to note that the Buprestidæ comprise 188 species, the Cerambycidæ 267 species, and the Meloidæ 57 species. The enterprise which prompted the compilation and actual publication of this bulky work deserves special commendation, and it is likely to remain the standard reference catalogue on its subject for many years to come.

Egg-killing Insecticide Washes.—During the winter, when vegetation upon the fruit tree is dormant, it is possible to use insecticide washes of considerable strength with the view of controlling insect pests then present on the bark in the form of eggs. During recent years there have been indications that the researches into the preparation of a successful egg-

killing wash, carried on at the experiment station at Long Ashton under the auspices of the Ministry of Agriculture, had met with considerable success. In a paper in the *Journal of Pomology*, vol. 8, pp. 129-152, May 1930, Messrs. Staniland, F. Tutin, and C. L. Wilson give an account of the progress of these investigations and show very clearly that the ovicidal powers of the successful tar distillate washes are due to the asphyxiating action of a uniform, oily film deposited over the eggs by the spraying operations. Direct toxic action of the active chemical constituents is relatively unimportant; experimentally, the eggs can be killed equally well by heavy medicinal paraffin. Paraffin wax and neutral tar products boiling above 360° C. were less successful ovicides, because, on drying, they did not yield a uniform film, but an irregular granular deposit. The control of capsid bug and the winter moth by the new 'high neutral' tar distillate washes, when a suitable emulsifier is used, seems to be exceedingly efficient on apple trees. On black currants capsid bugs are less easily controlled. The authors point out this may be because the egg protruded further into the air, out of the bark, and is therefore less readily covered by the drying film of oil. The destruction of *Aphis* and *Psylla* eggs by these washes, on the other hand, is not brought about by their asphyxiation, but by the directly toxic action on the eggs of certain chemical constituents in the washes. This paper, of great practical importance, is also of very considerable scientific interest, the practical results of field spraying trials being controlled by numerous laboratory experiments with the various constituents of the insecticide washes upon different types of insect eggs.

Grasses of Central America.—In his monograph of the grasses of Central America, Prof. A. S. Hitchcock (*Cont. U.S. Nat. Herb.*, Smithsonian Institution, vol. 24, part 9, 1930) brings together for the first time much scattered information relating to the grasses of the whole area between Colombia and Mexico. Native and introduced species are both included, and the paper gives descriptions of 115 genera and 460 species, including one new species, *Ichnanthus standleyi* Hitchc. from Honduras. The best represented genera are *Paspalum* and *Panicum*, each with more than 60 species. The grass flora falls into three types. In the tropical rain forests bordering the Atlantic coast the flora is similar to that of the other tropical American coastal lowlands bordering the Atlantic. The coastal region on the Pacific side is much drier and possesses a well-marked dry season, as a result of which there are extensive savannas extending from Panama to Mexico. The flora of elevated interior is high temperate rather than alpine, and the grass flora represents a southern extension of that of the Mexican plateau.

Hybrid Poplars for Pulp Production.—Throughout the world research work is now being undertaken, having for its object the increase in the production of paper, chiefly pulp, for the news sheets and cheaper forms of publications. During the past few years Dr. Ralph H. McKee and others have been carrying on research with the object of attempting to find means by which the steadily diminishing supplies of wood in the United States of America might be supplemented. Amongst other experiments entertained, attempts were made with hybrid poplars, the object aimed at being to obtain an increased rapidity of growth. Several hundred acres of waste land in the eastern parts of the United States have been planted with hybrid poplar trees (the species are not mentioned), which it is said will yield a crop of pulp wood for the paper industry comparable in value to the financial return from flaxstraw and cotton. Dr. McKee recently described this work before the Franklin Institute, a notice of which is given in *Daily Science News Bulletin*, No. 469 C (Washington, 1930). The new hybrids will produce, it is said, from 10 to 14 times as much wood per year as wild poplars growing under similar conditions. It was pointed out that in 60 years natural reforestation yields about six cords of useful wood per acre, or 125 pounds of cellulose a year from each acre. The yield per acre-year for cotton is 150 pounds of cellulose, for flaxstraw 100 pounds, and cornstalks nearly 500 pounds. "Well managed reforestation plantations of pulp wood using wild species produce about 2000 pounds of cellulose per acre-year," said Dr. McKee. "From the new hybrid poplar plantations we have every reason to expect 80 cords of pulp wood per acre in 12 years; that is, an average of about 16,000 pounds of merchantable wood per acre-year, equivalent to 8000 pounds of cellulose." The development of this interesting experiment will merit the most careful watching.

Carboniferous Fossils from Nova Scotia.—A collection of Carboniferous fossils from the Mississippian beds at Windsor, Nova Scotia, formed by the late Miss Eleanor Long in 1914, has been worked over by W. A. Bell (*Proc. Acad. Nat. Sci. Philad.*, vol. 81). The author, who has already prepared a paper on the district for the Geological Survey of Canada (*Memoir 155*), gives a summary of the general geology of the Windsor area, accompanied by a map, and enumerates the forty-six species of fossils in Miss Long's collection with special notes and figures of three. The Windsor fauna as a whole exhibits close affinity to the Viséen of western Europe, more especially the *Seminula* zone of England, and differs from the faunas of like age in the Mississippian basin of America, as early noted by Dawson and others.

Earth Pressure Experiments.—In connexion with the construction of a big retaining wall, 900 ft. long and 160 ft. high at mid-length, for a power scheme in New England, a series of large-scale experiments on earth pressure have been carried out in a laboratory especially erected for the tests, and an account of the investigation is given in *Engineering* for May 30 and June 13. The laboratory was erected on a site provided by the Massachusetts Institute of Technology, and the tests were made by Dr. C. Terzaghi, now professor in the Technical High School, Vienna. The testing machine employed consisted of a ferro-concrete bin 14 feet square, one side of which had a movable stiffened slab, the thrust against which could be measured by weighing machines. Boulder clay and till—the latter a geological term applied to a deposit of clay, sand, and gravel—were used in the experiments, the results of which are given in the articles. Experiments were also made on the internal frictions of sands and clays under different pressures, when it was found that, with identical materials and low pressures, the coefficient of friction was far greater with densely packed than with loose materials, but as the pressures increased the margin between the two values tended to disappear.

Structure of the Electron.—In a series of papers published since 1929 in the *Proceedings of the Physico-Mathematical Society of Japan*, Mr. U. Kakinuma endeavours to develop a new theory of the structure of the electron which shall combine the theory of relativity with wave mechanics. He starts by replacing the ordinary relativity electromagnetic energy-tensor by another energy-tensor which involves velocity components as well as electromagnetic terms, and is analogous to the usual energy-tensor of a perfect fluid.

From this assumption are derived the fundamental field-equations, which admit of a remarkable solution, with one factor such as appears in Einstein's cosmological theory, and a second factor which is periodic. Thus with every electron there is associated a wave of a definite frequency. Moreover, the solution leads directly to the fundamental equation of wave mechanics, connecting the mass of the electron with the frequency of the associated wave. It might be thought that Mr. Kakinuma's work is a development of Einstein's unitary field theory, but this is not so. It is more on the lines of the theory of gauges due to Weyl, of which little has been heard for several years, but it uses Riemannian geometry, which both Weyl and Einstein have now discarded.

X-Ray Crystal Analysis.—In the *Engineer* for July 4, Mr. V. E. Pullin, director of radiological research at Woolwich, in a well-illustrated article on X-ray crystal analysis in engineering gives a broad outline of the object, the methods, and the results of the application of the X-ray spectrometer to various metals and alloys used in engineering. Starting with a brief note on the discoveries of Von Laue and other investigators, he says that the important facts which render X-ray crystal analysis of use to engineers are first, that metals are crystalline, and second, that the working of metals either by tools or by heat always tends to alter or modify the crystal structure. This being so, it is the function of X-rays to show the manner in which individual atoms are normally arranged, and how they are modified by mechanical or heat treatment or by alloying with other metals. After a short explanation of the types of crystals of importance to engineers, (1) face-centred cubic crystals, (2) body-centred cubic crystals, and (3) hexagonal crystals, Mr. Pullin goes on to describe the apparatus and the technique, and then gives a series of examples of the information that can be obtained. He gives some forty or more characteristic diagrams which are published in a special supplement.

Compressibilities of Gases. The April number of the *Journal of the American Chemical Society* contains three papers dealing with the compressibility of hydrogen and nitrogen and of a 3 : 1 mixture of these gases at temperatures of 70°, −50°, −25°, and +20°, and at pressures up to 1000 atm.; of carbon monoxide at temperatures from −70° to +200°, and at pressures to 1000 atm.; and on a characteristic equation with relation to nitrogen. In the case of nitrogen, a curious phenomenon appeared at about 380 atm., when the deviation from the ideal gas was nearly constant through the temperature range −70° to +100°. Carbon monoxide was found to undergo decomposition under pressure at atmospheric temperature when stored in iron vessels. Carbon and carbon dioxide are formed, and at 100 atm. the gas contained more than 1 per cent of carbon dioxide after three weeks. Formation of iron carbonyl also occurred. The compressibility curves of carbon monoxide are similar to those of nitrogen: carbon monoxide is slightly more compressible than nitrogen in the low-pressure range and slightly less compressible in the high-pressure range, the difference becoming smaller with increasing temperature. The results are to be expected from the fact that carbon monoxide has a slightly higher critical temperature (−139·0°) than nitrogen (−147·1°). Carbon monoxide exhibits the same peculiar behaviour as nitrogen, but over an even wider range of temperature, namely, from −70° to +200° at 375 atm.

Chemistry of Coal.— A paper on the benzenoid constitution of coal (Part 6 of a series on the chemistry of this substance) has been contributed to the June number of the *Proceedings of the Royal Society* by Prof. Bone, Dr. L. Horton, and Mr. S. G. Ward. The elaborate series of experiments performed, mainly on the oxidation by permanganate of the residues from the 'benzene-pressure-extraction' of various coals, have lead to results of much importance. All the coal residues examined gave much the same weight-yields of crystalline organic acids, chiefly benzene carboxylic acids, the proportion of which did not vary materially from one coal to another, and smaller amounts of oxalic and acetic acids, indicating that "a considerable part of the organic débris originally deposited in the incipient coalfields either had or soon acquired a cyclic, and probably benzenoid, structure which has been preserved during the subsequent maturing process". Evidence has also been obtained that in the oxidation of the coal substance by alkaline permanganate, complex colloidal 'humic acids' are formed intermediately, the crystalline benzenoid acids, and probably also oxalic and acetic acids, arising simultaneously from their further oxidation. These results, and others obtained in earlier work, "revealing as they do that in great part the coal substance—no matter what its geological age or chemical maturity, or whether or not it is extractable by boiling benzene under pressure—has an essentially 'benzenoid' structure, suggest the possibility of its having arisen through condensations of phenolic- and amino- with aldehydic-bodies, much as 'bakelite' is synthesised nowadays from phenols and formaldehyde". The experimental exploration of the many questions opened up by this investigation—which have been necessarily referred to only in certain salient points in the present note—is being continued, but it is evident that the researches already performed have led to a considerable advance in knowledge of the properties of coal.

Radio Communication with Aeroplanes.—Mr. Hoover, the radio engineer of the Western Air Express, read a paper on radio communication with aeroplanes to the Society of Automotive Engineers in the United States on Feb. 20. The difficulties to be overcome are mainly due to the radio waves emitted by the engine every time a spark occurs in any of the sparking plugs—the ignition wires, magneto, and low tension wires forming an antenna system. The highly sensitive receivers on the aeroplanes have to pick up feeble signals from stations more than a hundred miles away. It will be seen, therefore, how difficult it is to shield from the receiver the waves coming from strong spark transmitters only ten feet away. The only possible solution is to put a continuous metallic shield round all the radiating apparatus. The Airways Division of the U.S. Department of Commerce has initiated the building of earth stations for aeronautical use. About forty stations have already been installed. They are spaced along the airways at distances apart of about 200 miles. They cover the whole country from New York to San Francisco and from Seattle to Key West. The stations use the voice and have a carrier output of two kilowatts. On a conservative estimate this would give a day range of about 150 miles and a night range of double as much. The 1927 international convention set aside a band of wave-lengths between 800 metres and 1200 metres exclusively for aeronautical purposes, and the Government stations work between these limits. A new branch of the U.S. Weather Bureau has been inaugurated to make hourly collections and forecasts of the weather. The reports are collected and broadcast over the airways every hour and it is hoped shortly to broadcast them every half-hour.

The Third Imperial Entomological Conference.

THE Third Imperial Entomological Conference was held in London, under the auspices of the Imperial Institute of Entomology, on June 15-27. Through the courtesy of the officers and council of the Entomological Society of London the meetings of the Conference were held at the headquarters of the Society at 41 Queen's Gate. About forty delegates, representing twenty-four different States of the British Empire, attended in an official capacity. Lord Buxton, the chairman of the managing committee of the Imperial Institute of Entomology, was unfortunately unable to be present owing to illness, and was represented at the opening meeting by Sir Sidney Harmer. The morning of the first day of the Conference was devoted to the reception of delegates and the appointment of sub-committees to deal with business matters. At this meeting it was announced that the Managing Committee had decided to alter the name of the Imperial Bureau of Entomology to the Imperial Institute of Entomology, in view of the growth and expansion of its work since it was first founded. In the afternoon the delegates were shown a very remarkable film brought from Canada by Mr. A. Gibson, Dominion Entomologist, representing the mass production of the parasites of the European corn borer, as carried on in the laboratory of the Dominion Entomological Department at Chatham, Ontario. In this film the various phases of the mass production work and the behaviour of the principal parasites of the pest studied were shown with extraordinary clearness and accuracy. The film was exhibited at the Imperial Institute through the courtesy of the Director, Lieut.-Gen. Sir W. T. Furse, and was again shown by request on Friday, June 20. The exhibition of the film was followed by a reception of the delegates at the Natural History Museum.

The meetings of June 18, under the chairmanship of Mr. F. A. Stockdale, were devoted to discussions on the organisation of entomological departments, opened by Mr. H. H. King, of the Sudan, and on entomological work among backward races, opened by Mr. A. H. Ritchie, of Tanganyika. In the evening there was a meeting of the Entomological Society of London, which was largely attended by the delegates.

On Thursday, June 19, the delegates visited the Parasite Laboratory at Farnham Royal, where they were entertained by the Imperial Institute of Entomology to luncheon and tea, and shown in detail the various methods in use in the work of the laboratory.

The morning meeting of June 20, held under the chairmanship of Dr. T. Drummond Shiels, M.P., was devoted to the extremely important subject of tsetse control. The discussion on this subject was opened by Mr. C. F. M. Swynnerton, whose excellent work in areas infested by the tsetse in Tanganyika Territory is, of course, well known. Mr. Swynnerton gave a detailed and most interesting account of the work which is now being carried on in Tanganyika, where the practice of grass burning, carried out under skilled direction and combined with the breaking up of the infested zones into areas of a size convenient for burning, has given excellent results. A very important phase of this work has consisted in the production of live fences or hedges designed to prevent the passage of game, and produced by the planting of cuttings or live poles of certain species of indigenous trees which are used by the natives to fence their villages. Another important development in this work is the use of moving baits smeared with tanglefoot for the capture of individual flies, and the introduction of the aeroplane for scouting work. The importance of aeroplane surveys in entomological work is now widely recognised, and it is to be hoped that every facility for their use will be granted by the authorities, in order that this work may be carried on in the infested areas in a thorough and satisfactory manner. Mr. Swynnerton's paper was followed by a very interesting discussion on various phases of the tsetse problem, including the important matter of game preservation. The afternoon meeting, under the chairmanship of Mr. A. Gibson, Dominion Entomologist for Canada, was devoted to the control of insects by cultural methods, and was opened by Mr. F. A. Stockdale. It gave rise to a number of very important comments in regard to the value of cultural methods, particularly against sucking insects, in various parts of the world.

Saturday, June 21, was devoted to a visit to the University of Cambridge, where the delegates were entertained by Prof. J. Stanley Gardiner, and shown the work conducted by the Department of Entomology and the important investigations in progress on virus diseases of plants. The delegates were entertained to tea at Messrs. Chivers' fruit farm.

The morning of Monday, June 23, was devoted to the meetings of committees and the afternoon meeting to the important subject of locusts, under the chairmanship of Major E. E. Austen. The discussion was opened by Mr. B. P. Uvarov, of the Imperial Institute of Entomology, one of the foremost living authorities on this subject. Unanimous agreement was expressed by all the speakers as to the necessity for further investigations on the permanent breeding-grounds of the migratory locusts and the underlying causes of the phenomenon of migration.

On the following day the meetings, which were held under the chairmanship of Sir Sidney Harmer owing to the unavoidable absence of Dr. R. Stewart MacDougall, were devoted to the subject of biological control, which is now of especial interest owing to the fact that since the previous Conference the Imperial Institute of Entomology has founded, with the aid of a grant from the Empire Marketing Board, its laboratory at Farnham Royal as an Imperial centre for work on biological control of insect and plant pests. In the morning meeting the biological control of insects was considered. It was opened by Mr. A. Gibson, who gave an interesting and detailed account of the work in progress on these lines in the Dominion of Canada. In the discussion that followed, many points of interest were brought up concerning the practice of biological control of insect pests in various parts of the world, and general satisfaction was expressed by all the delegates in regard to the initiative which Sir Guy Marshall, director of the Imperial Institute of Entomology, had taken in the creation of a special institution for work of this type within the Empire. The afternoon meeting was devoted to the control of weeds by insects. Dr. Miller, of the Cawthron Institute of New Zealand, who opened the discussion, gave an account of the work which is being carried on in New Zealand in collaboration with the Imperial Institute of Entomology at Farnham Royal on the biological control of some of the most important weeds of New Zealand, including particularly blackberry, gorse, ragwort, and bracken. He was followed by Dr. A. Nicholson, deputy chief of the Entomological Division of the Commonwealth Council for Scientific and Industrial Research of Australia, who described to the delegates the extraordinarily successful and interesting experiments carried on by the Commonwealth Prickly Pear Board against the various species

of prickly pear in Australia. He showed that the initial successes obtained in this work have now been very greatly extended, and that large areas formerly rendered uninhabitable and useless for agricultural purposes by the invasion of the prickly pear have now been freed completely from this pest and are being brought under cultivation.

The morning of June 25 was devoted to meetings of committees, and the afternoon to a discussion, opened by Dr. W. J. Hall, of orchard pests in various parts of the world. In the evening an official dinner was given to the delegates by His Majesty's Government at Lancaster House, St. James's, under the chairmanship of Lord Passfield, Secretary of State for the Colonies.

The final meeting of the Conference was held on June 26, and was followed on Friday, June 27, by a visit to the Rothamsted Experimental Station and Pathological Laboratory of the Ministry of Agriculture at Harpenden. W. R. THOMPSON.

Cellulose and Sodium Hydroxide.

THE British Cotton Industry Research Association has recently issued two memoirs (reprinted in the *Journal of the Textile Institute*, vol. 20, T. 373, 1929; and vol. 21, T. 225, 1930) in which S. M. Neale describes some work on the physical chemistry of cellulose. Regarding cellulose as a linked series of glucose residues with –OH and -O- groups as reacting points, it is shown that the behaviour in alkaline solutions can be explained by treating the –OH groups as sources of potential acidity, with their capacity for liberating hydrion governed by the law of mass action, so that an average dissociation constant can be assumed for the primary acid ionisation of cellulose in any state of complexity. In developing this idea it is necessary to employ the Donnan equation of membrane equilibrium to allow for the fact that the assumed cellulose ion is coherent and unable to diffuse. By assuming an approximate value of 2×10^{-14} for the dissociation constant it is possible to calculate approximately the osmotic swelling pressure of cellulose in solutions of caustic soda of any concentration. The calculated osmotic pressure curve is strikingly similar to the curve obtained by plotting the imbibition of water by regenerated cellulose (cellophane sheet) against the concentration of alkali in which it is placed, while the amounts of alkali taken up are shown to be consistent with the stoichiometric conversion of cellulose into the mono-sodium salt at high alkali concentrations, when allowance is made for the alkali imbibed in accordance with the Donnan equation.

The peculiar effect of temperature on the swelling curve of cellulose in sodium hydroxide solution is a consequence of the theory and arises essentially from the increasing hydrolysis of the cellulose salt at high temperatures. The amount of heat developed in the reaction between cellulose and sodium hydroxide has been determined and is found to rise continuously with the concentration of the alkali. The heat effects at all concentrations are in fair agreement with values calculated on the assumption that the heat of ionisation of cellulose is comparable with that of the monosaccharides. Allowance is made in these calculations for the very large additional heat effects arising from the higher energy content of alkali in concentrated as compared with dilute solution, and from the dilution of the bulk alkali by the water molecules set free and those formed as a result of the postulated chemical reaction.

When cellulose in equilibrium with any given solution is immersed in a solution of widely different concentration, striking transient volume changes are observed. These are explained in terms of the osmotic theory which is put forward, and arise from the fact that the water diffuses more rapidly than the alkali. The data presented in the second paper describe the behaviour of regenerated cellulose in solutions of sodium hydroxide more dilute than half-normal, and it is shown that in this region the absorption of alkali and the swelling of the gel are quantitatively explained by assigning to the ionisation constant of cellulose the value $1{\cdot}84 \times 10^{-14}$ at 25° C.

The considerations of these papers are largely applicable to the behaviour of cotton hairs in caustic alkali, and go far towards making clear the chemical and physical mechanism of the process of mercerisation.

Geology of Ceylon.

IN the little pamphlet referred to below [1] Dr. Adams brings together the work of former investigators in Ceylon, savouring his account with important conclusions derived from observations of his own. The geological structure of the island is outlined for the first time, analyses of rocks are given and, above all, there is an admirable geological map, the first of the whole island to be produced. A list comprising seventy references is provided.

The historical side is touched on briefly in an "Introduction", wherein it is stated that man had not reached the Palæolithic stage, when probably "by means of a then existing land bridge" he arrived on the island. The successive invasions from Neolithic time to the occupation by the British in 1796 are summarised in a few paragraphs. After a review of earlier publications, Dr. Adams deals with the topography and brings out clearly the three peneplanations to which the land has been subjected, illustrating his explanation with four admirable plates, two being reproductions of sheets of official maps.

Investigators in Ceylon are fortunate in having such a sound basis for their work as this topographical survey produces. To these three peneplains, clearly visible, must be added a fourth, the submarine plateau. The subaerial surfaces of erosion, representing stationary conditions in a periodically renewed upward movement, are respectively 100 feet (the coastal plain), 1600 feet and 6000 feet above sea-level and are of more than local interest. Whether they are or are not due to marine erosion is left an open question—the author inclines to subaerial denudation—one notes in passing that Wayland assigns the first and second to the former cause. Dr. Adams suggests that the Deccan Plateau is perhaps a continuation of the second, possibly the uplands of the Nilgiris represents the third planation, making the comment that so well defined a series of erosion surfaces may yet be recognised in other fragments of 'disrupted' Gondwana Land. He suggests Madagascar in this connexion. The present writer would add the Northern Frontier Province of Kenya; the type of country, a wide stretching plain with suddenly rising 'buttes' or residual hills, is essentially the same as that shown by Dr. Adams in Plate II.

As it must be, the topography is influenced by the strike of the foliation of the crystalline rocks, but in Ceylon ("an admirable relief map of the island" exists in Colombo) the strike ridges swing in successive loops resembling, as Dr. Adams has it, "a series of garlands pendent from the northerly extremity of the Island";

they follow approximately the outline of the coast. The island, in fact, is a portion of a much eroded syncline, the axis in general trending north and south a short distance east of Kandy and Nuwara Eliya. Altogether, this is a stimulating portion of the book.

For the Pleistocene, the Miocene at the extreme north of the island and the very small area of non-marine Jurassic beds at Tabbowa, the author relies principally on data collected by Wayland; for the Archaean, which constitutes so very large a proportion of the whole, Coomáraswámy is a noteworthy contributor. Acknowledgment for information received, especially concerning the gem deposits, is made to Mr. J. S. Coates, the Principal Mineral Surveyor. The crystalline rocks present many interesting features, and the resemblances they bear to those of other lands attract Dr. Adams's attention. He points out the essential identity of the dominant quartzose biotite-gneisses with "hundreds of occurrences in the Laurentian of Canada" and the "striking resemblance" of the limestones to those of the Grenville Series of the Canadian Shield. Doubtless the island is the southward extension of the Bengal gneiss with which, in Ceylon as in India, khondalites are associated. Of these analyses are given. Nine analyses of charnockites and four of allied rocks, together with a table of norms, increase our knowledge of that interesting series. Much petrographical detail is provided, but a few photomicrographs would have added to the value of the work.

The geological map, with an east and west section through the island, shows the limestones, quartzites, and khondalites differentiated from the huge expanse of biotite-gneiss, the distribution of the charnockites in the southern part of the island and in addition the Galle Series of Coomáraswámy, a group distinguished by the occurrence of scapolite and wollastonite. The strike of the foliation is made clear by broken lines. Doubtless, as Dr. Adams comments, there is yet room for additional study in Ceylon, but in this work we have the most valuable contribution to the geology and physiography of the island produced for many years.

JOHN PARKINSON.

University and Educational Intelligence.

BIRMINGHAM.—At the recent degree congregation the degree of D.Sc. was conferred on Mr. Edward Tyler for published work on liquid jets, vortices behind aerofoil sections and rotating cylinders, eddy flow from annular nozzles, and other aerodynamic investigations.

Dr. H. B. Keene is resigning his post as lecturer in physics on being appointed head of the Physics Department of the Birmingham Municipal Technical College.

The fiftieth anniversary of the opening of Mason College and the thirtieth anniversary of the granting of the charter to the University of Birmingham are to be celebrated in October, the programme including a special degree congregation at which honorary degrees will be conferred on, among others: Sir William Hardy, Prof. R. Robinson, Dr. F. E. Smith, and Sir Thomas Lewis.

EDINBURGH.—At a meeting on July 14, the University Court accepted the resignation of Mr. J. G. Semple, lecturer in mathematics, on his appointment to the chair of mathematics at Queen's University, Belfast. Mr. Alexander Oppenheim was appointed lecturer in mathematics in place of Mr. Semple. The resignation of Mr. L. A. Harvey, lecturer in zoology, was intimated on his appointment as head of the department of zoology in the University College of the South-West at Exeter.

LONDON.—The following appointments have been made: Dr. Samson Wright, lecturer in physiology at King's College, to be University professor of physiology (Middlesex Hospital Medical School); Dr. Alexander Robertson, University reader in chemistry at East London College, to be University reader in biochemistry (London School of Hygiene and Tropical Medicine).

Mr. J. G. Thomson (medical protozoology) has been given the title of professor in respect of the post held by him at the London School of Hygiene and Tropical Medicine.

Dr. G. S. Wilson (bacteriology as applied to hygiene) has been given the title of professor in respect of the post held by him at the London School of Hygiene and Tropical Medicine.

The title of emeritus professor of physics in the University has been conferred on Prof. C. H. Lees on his retirement from East London College.

OXFORD.—Applications are invited from members of Magdalen College for the Edward Chapman research prize, value £20, for a published piece of original research in one of the following departments of natural science: physics or chemistry, including the sciences of astronomy, meteorology, and mineralogy or geology, or the biological sciences of zoology and botany, whether treated from the morphological, palæontological, physiological, or pathological point of view. Competing essays should be sent by, at latest, Oct. 11 next, to Prof. H. L. Bowman, Magdalen College.

THE Ramsay Memorial Fellowships Trustees have made the following awards of new fellowships for the session 1930–31: Mr. W. R. Angus, a fellowship of £300, tenable for two years, at University College, London; Dr. K. Krishnamurti, a fellowship of £300, tenable for one year, at University College, London; Dr. James Bell, a Glasgow fellowship of £300, tenable for two years, at University College, London; Dr. A. Girardet, a Swiss fellowship of £300, tenable for one year, at the University of Edinburgh. The Trustees have renewed the following fellowships: Dr. H. Erdtman (Swedish Fellow), University College, London; Dr. A. Klinkenberg (Netherland Fellow), University of Cambridge; Prof. Y. Nagai (Japanese Fellow), University College, London; Dr. Lloyd M. Pidgeon (Canadian Fellow), University of Oxford.

NOTICE is given by the President and Council of the Royal Society of forthcoming awards of Moseley, Mackinnon, and Lawrence research studentships. The first-named will be for "the furtherance of experimental research in pathology, physics, and chemistry, or other branches of science, but not in pure mathematics, astronomy, or any branch of science which aims merely at describing, cataloguing, or systematising", and the value £350 per year; the second will be for the purpose "of furthering (i) natural and physical science, including geology and astronomy, and (ii) original research and investigation in pathology", and the value £350 per year; the third will be of the value of not more than £200 for one year, for research in some subject related to the cause and cure of disease in man and animals. Forms of application, returnable not later than Oct. 11, may be obtained from the Assistant Secretary of the Royal Society, Burlington House, London, W.1.

Historic Natural Events.

July 28, 1883. Destructive Ischian Earthquake.—Casamicciola, the chief town in the island of Ischia (Italy), was destroyed by an earthquake and about 1800 out of 3963 inhabitants were killed. The area of complete destruction, however, contained only 3 square miles, and the whole disturbed area between 300 and 400 square miles, that is, less than the area of a slight British earthquake. This implies a very shallow focus, the depth of which was estimated from the directions of fissures to be one-third of a mile. The epicentral area lay on the northern slope of Epomeo, a volcano that was last in action in 1302, and its longer axis was directed towards the centre of the old crater. Thus, the earthquake may have been the result of an unsuccessful attempt to force a new eruption.

July 29, 1875. Shower of Hay near Dublin.—About 9.30 A.M. a quantity of hay fell from the sky at Monkstown near Dublin, over an area of more than a mile in diameter, the shower lasting five minutes. There was a dark cloud overhead and the hay was wet, but no rain was falling, and the air was very calm.

July 29, 1911. Thunderstorms over the British Isles.—A line-squall traversed the British Isles from south to north between 2 P.M. on July 29 and 9 A.M. on July 30, and in the southern half of the country it was associated with violent thunderstorms and strong squalls. At South Kensington 1¼ inches of rain fell in a short time. The storm caused remarkable tidal oscillations in the English Channel, the water rising suddenly 3 feet with the onset of the squall.

Aug. 1, 1785. Swarm of Aphides at Selbourne.—Gilbert White records that about 3 P.M. a shower of Aphides or smother-flies fell in Selborne, blackening all the plants and covering persons walking in the streets. They were observed at the same time in great clouds about Farnham, and all along the vale from Farnham to Alton, and were probably migrating from the hop-fields of Kent.

Aug. 1, 1798. Mirage at Ramsgate.—A remarkable mirage was observed by the Rev. S. Vince from Ramsgate from about 4.30 P.M. until between 7 and 8 P.M. The day had been extremely hot and the evening was very sultry. The masts and upper sails of a ship were seen through a telescope; above it was a perfect inverted image of the same ship and a part of the surface of the sea, and above that again, and joined on to it, a third image showing the ship erect, these two images having their hulls joined. Similar effects were seen with various other ships. Most of the observations were made from a height of 25 feet, others from 80 feet, the phenomena not being altered by the change of height.

Aug. 1, 1846. Hailstorm in London.—During a violent hailstorm the glass in the picture gallery at Buckingham Palace was totally destroyed and the gallery flooded. 7000 panes of glass were broken in the Houses of Parliament and 10,000 at Burford's Panorama in Leicester Square. The glass arcade then covering the side walks in Regent Street was destroyed and the Surrey Theatre was flooded.

Aug. 1-6, 1901. "De Witte" Typhoon.—One of the most violent typhoons which have been systematically studied approached China, travelling in a west-north-west direction, on Aug. 1, 1901, and struck the coast in lat. 27° N. on the afternoon of Aug. 2. Thereafter it travelled on a great curve through Fuhkien, east of Kiangsi and across the province of Chekiang, and continued across Asia towards the north-north-west, a very abnormal path. Off the coast the barometer in the central calm fell to 915 mb. (27·03 in.). The storm is known for the destruction of the Russian vessel *Finanzminster De Witte*, a powerfully engined and well-found steamer of 2000 tons, less than two years old, which was knocked to pieces by the heavy seas.

Aug. 1, 1907. Ball Lightning at Alpena, Michigan.—On Aug. 1, 1907, during a heavy shower with thunder and lightning, a ball of lightning about six to eight inches in diameter entered a house. It dropped lightly on to the floor, moved round the room in circles, then entering the wall, moved up inside it and came out a few feet above the window. A four-inch brace was splintered and much plaster was forced into the room. The ball then travelled across the room again and out of the other wall, making a ragged hole. It struck into the earth about 30 feet from the house, leaving a hole about 6 inches wide and a few inches deep.

Aug. 2, 1837. The Hurricane of Los Angeles.—This was probably the most severe hurricane ever experienced in Porto Rico; it lasted only five hours, but its violence was so excessive that all the ships in the harbour of San Juan were wrecked and great damage was done to property throughout the island.

Aug. 2, 1906. Guildford Storm.—After a very hot day violent thunderstorms broke over south-east England during the evening, the most violent occurring between Hindhead and Ripley, and especially at Guildford. At Grayshott 1·17 in. of rain fell in 15 minutes between 8·23 and 8·38 P.M., accompanied by a violent squall. At Guildford the low-lying parts of the town were flooded to a depth of several feet and a great deal of damage was done by the wind and hail. Many large trees were blown down and several buildings wrecked, while there was some loss of life.

Aug. 2-3, 1922. Swatow Typhoon.—This storm, one of the worst in history in the China Seas, was first observed as a slight disturbance near the Caroline Islands on July 27. It moved towards the west-north-west, gradually increasing in intensity. On July 31 it was over northern Luzon, where it turned more towards the north and crossed the Chinese coast on the night of Aug. 2–3, the centre passing directly over Swatow. The barometer fell to 938 mb. (27·70 in.), the wind was very violent and the rain torrential. Both foreign and native shipping suffered heavily, but the worst damage was done by an enormous sea wave, which crossed the mud-flats in front of the city early on the morning of Aug. 3, and washed away all the houses which had not been blown down. Out of a population of 65,000 persons, it is estimated that 50,000 lost their lives, and it was several days before the water drained off the countryside.

Societies and Academies.

DUBLIN.

Royal Irish Academy, June 23.—**J. I. Armstrong, J. Calvert**, and **C. T. Ingold**: The ecology of the mountains of Mourne, with special reference to Slieve Donard. The vegetation of the area is mostly *Callunetum* of various types, growing on peat covering granite rock. The peat is mostly retrogressive, especially at high altitudes; rarely a progressive peat formation was seen. Examination of the peat (one station, 518 metres) shows in a two-metre section an extraordinary increase of pollen-grain at 66 cm. from the surface. All the pollen is considered to be wind blown.—**J. M. White**: Re-colonisation after peat-cutting. Studies were made mainly in Co. Armagh, where peat-cutting is still carried on on a considerable scale. The depth to which peat-cutting is carried was found to be the most important factor in the re-colonisation of the cut areas, when combined with the time factor.—**Miss M. Duff**: The ecology of the Moss-

Lane region, Lough Neagh. Gives a detailed account of the vegetation around Portmore Lough, which is the home of many rarities of the Antrim flora, and of much interest ecologically.—**K. C. Bailey**: The kinetics of the formation of malonamide from ethyl malonate and ammonia in homogeneous solution. A reaction of the third order. The reaction between ethyl malonate and ammonia in aqueous alcoholic solution takes place in accordance with the equation $v = k\ a\ b^2$, where v is the velocity of reaction, and a and b are the concentrations of ethyl malonate and ammonia. The velocity is increased by increasing the proportion of water in the solvent.—**Elizabeth Mary Ryan and Hugh Ryan**: Studies in the diflavone group (5). Metamethoxybenzaldehyde and diacetoresorcinol. In the presence of alcoholic alkali m-methoxybenzaldehyde condenses with diacetoresorcinol-dimethylether to form di-m-methoxybenzylidene-diacetoresorcinol. Nearly colourless prisms. M.P. 157°-158° C. Its dibromo derivative consists of prisms M.P. 213° C. (decomp.) and its tetrabromide also melts with decomposition about 176° C. With diacetoresorcinol m-methoxybenzaldehyde forms two chromisomeric *unsaturated ketones*. Both melt at 157° C. but one is orange yellow and the other is light yellow in colour. They form the same diacetate. Cream-coloured prisms. M.P. 122° C. The tetrabromide of the last body did not crystallise but was converted by alcoholic potash into nearly colourless crystals melting at 277°-279° C. which consisted mainly if not entirely of 3′·3″-dimethoxydicourmaranone. The dipiperonylidene derivative of 3′·3″-dimethoxy-diflavanone was obtained as yellow prisms melting at 245° C. by the action of piperonal on di-m-methoxy-benzylidene-diacetoresorcinol in the presence of alcoholic hydrochloric acid. Under the same conditions benzaldehyde formed the dibenzylidene derivative of the diflavanone and this consisted of yellowish-white prisms melting at 249° C. —**L. B. Smyth**: The carboniferous rocks of Hook Head, Co. Wexford. The Lower Carboniferous of Hook Head is conformable with O.R.S. The finding of *Avonia* (*Productus*) *bassa* Vaughan at the very base of the calcareous series shows that no appreciable amount of the underlying sandstones and conglomerates can be of Carboniferous age. The *K.Z* and *C* zones of Vaughan are identified. The latter two form a continuous zaphrentid phase, as in south Pembrokeshire. C_2 is recognised but it is uncertain whether S_1 is present. It is now proved that there is only one dolomite band, repeated by faulting (not two as previously believed) and that it is of *laminosa* dolomite age. The total thickness of Carboniferous beds exposed is 1300 feet. At the top they disappear under the sea. Several new species are described, and '*Michelinea*' *antiqua* (M'Coy) is shown to be a degenerate tabulate coral with porous tissues.—**Brian Coffey and Hugh Ryan**: The constitution of certain compounds formed by the action of alcoholic hydrochloric acid on unsaturated ketones. In a previous paper Coffey and Ryan (Royal Irish Academy, 39, B. 3) showed that where alcoholic hydrochloric acid acts on alcoholic solutions of unsaturated ketones such as a-benzylidene methylethyl-ketone, dimerisation takes place and compounds of the type represented by the formula I are formed.

$$\begin{array}{ccc} C_6H_5\cdot CH & \text{——} & CH\cdot CO\cdot CH_2\cdot CH_3 \\ | & \mathrm{I} & | \\ C_6H_5\cdot CH & \text{——} & CH\cdot CO\cdot CH_2\cdot CH_3 \end{array}$$

In the present communication an account is given of the monoxime of the compound I and of a compound formed by the action of phosphorus pentoxide on solutions in benzene of the monoxime. It appears that only monoxime is formed of the compound I and that by the action of phosphorus pentoxide internal rearrangement takes place with formation of the amide.

$$\begin{array}{ccc} C_6H_5\cdot CH & \text{——} & CH\cdot CO\cdot CH_2\cdot CH_3 \\ | & \mathrm{II} & | \\ C_6H_5\cdot CH & \text{——} & CH\cdot CO\cdot NH\cdot CH_2\cdot CH_3 \end{array}$$

R. W. Ditchburn: The uncertainty principle in quantum mechanics. The theory of errors and uncertainties in physical measurements is discussed so as to distinguish clearly between possible error and probable error. The discussion is applied to the formulation of the uncertainty principle. It is shown that the term 'product of the possible errors' is meaningless and that discussions which relate solely to the probable errors are likely to be misleading. It is suggested that the real meaning of the principle is contained in Bohr's probability theorem (Birtwhistle, "Quantum Mechanics", p. 280), no more precise formulation being possible.

PARIS.

Academy of Sciences, May 26.—**Ch. Achard and A. Arcand**: The lipidic phosphorus accompanying the globulins in the blood serum and in serosities. After extraction with acetone and ether the remaining proteins still contain a lipidic residue, and this can be extracted by Kumagawa's method. It consists mainly of sterols, with a small proportion of lecithine. —**André Blondel**: The conditions of stability of a turbo-alternator connected with a network of mains, taking the governor into account.—**P. Vincensini**: A transformation of surfaces with total constant negative curvature.—**Georges Durand**: Local properties and ensemble of points without tangent plane of the envelopes of spheres.—**F. Marty**: Some properties of normal families of meromorph functions. —**Georges Valiron**: On the differential of a meromorph function and on certain functional equations.—**Émile Merlin**: Some properties of perfect fluids, with spiral striæ in rotation.—**Paul Bary**: The vapour pressure of jellies. A discussion of the reason why a fragment of jelly can, under certain conditions, partially dry in an atmosphere saturated with water vapour.—**Charles Dufraisse and Léon Enderlin**: Researches on structures susceptible of exhibiting reversible oxidation: study of the benzofurane group. In a search for the grouping which endows rubrene with the property of reversible oxidation diphenyl-benzofurane was examined, but it was found that the photo-oxidation of this compound did not give a dissociable oxide.—**Paul Gaubert**: The influence of foreign materials held in suspension in the mother liquor on the facies of crystals. Methylene blue, added to a solution of lead nitrate, may give, according to the conditions of crystallisation and the quantity of particles in suspension in the liquid, either crystals in cubes or crystals more or less flattened along the faces of the octahedron. The crystalline form of lead nitrate is also modified by the presence of rosolic acid in suspension.—**R. Fabre and H. Simonnet**: Contribution to the study of the oxido-reducing power of the tissues.—**Mme. L. Randoin and Mlle. A. Michaux**: The lipocytic coefficient of the red corpuscles and the globular resistance in the course of experimental scurvy.—**Mlle. Andrée Courtois**: The high proportion of non-proteid nitrogen in insects.—**H. Bierry and B. Gouzon**: The influence of the pH on a colour reaction of the adrenalines. A steel needle, placed in an aqueous solution of adrenaline hydrochloride, gives rise to a series of colours depending on the ionic acidity of the liquid.—**Henri Devaux**: The connexion between the organisation and the vital activity. The rôle of the plasmic membranes.—**Mme. Y. Khouvine, E. Aubel, and L. Chevillard**: The transformation of pyruvic acid into lactic acid in the liver.—**Paul Durand and Ernest Conseil**: The experi-

mental transmission of Marseilles exanthematic fever by *Rhipicephalus sanguineus*.

CAPE TOWN.

Royal Society of South Africa, April 16.—**M. R. Drennan**: On a ground stone axe from a Cape Rock shelter. Cultural and other remains found on excavating a small rock-shelter at Witsands, in the Cape Peninsula. The implements retrieved were practically all of the type usually met with in the Kitchen-midden culture of South Africa. The most important find was a ground stone axe with a large grooved slab on which the polishing might have been done. The special features of the stone axe are described, especially its unique hafting notch, only paralleled in the culture of the Australian aboriginal, which supplements the evidence we already have that some of the South African aborigines fixed handles to their stone implements.—**A. J. H. Goodwin**: (1) Some ground axes from Rhodesia and the Transvaal. A description of six specimens of ground axes, four from Rhodesia and two from the Transvaal. They are associated with a Neanthropic culture of known type, namely, the Smithfield.—(2) A new variation of the Smithfield culture from Natal. A hitherto undescribed industry showing marked similarity to certain phases of the Smithfield culture of the Free State and elsewhere. It is probably a Natal variation of the Smithfield, fed from the phase known as Smithfield *A*, and has been named Smithfield *N*.—**P. v. d. R. Copeman**: Changes in the composition of oranges during ripening (Pt. 1): Changes in weight. Weight of orange, skin and pulp increase, and the changes may be expressed by an autocatalytic equation. At the end of ripening transpiration becomes the dominating factor in growth and the respective weights decrease. Spraying with lead arsenate mixtures does not produce any significant effects upon these factors. The weight of residue per fruit in the sprayed oranges remains practically constant during ripening, while it decreases in the unsprayed oranges. It would appear that the arsenate spray exerts an internal physiological action, resulting in a reduction of the 'active mass' of the cell-wall material.—**A. J. H. Goodwin and W. E. Jones**: A new stone implement technique from Natal. A series of minute cuts occur along the edge of stone implements of a hardened shale, discovered at Mfongosi, Zululand, by Mr. Jones. If these are human in origin they constitute an entirely new technique, hitherto undescribed; if of non-human origin they may illustrate the gnawing habits of a rodent, probably a field-mouse.

SYDNEY.

Royal Society of New South Wales, May 7.—**Leo A. Cotton**: An outline and suggested correlation of the Pre-Cambrian formations of Australia (Presidential Address). The study of the distribution and structure of the Pre-Cambrian rocks in Australia discloses three great massifs, the largest of which forms the greater part of Western and South Australia, embracing marginal areas in the adjacent states. For this block the name 'Yilgarna' is suggested. A second block forms a broad zone about the Gulf of Carpentaria, extending from Darwin on the west to the east coast of Queensland, north of Mackay. This is called the Carpentaria massif. The third massif is the Tasmantis of David and Sussmilch: the fourth and smaller massif is recognised in the Kimberley district. Between Yilgarna on the south-west, and the Carpentaria massif and Tasmantis on the north and east, lies the great Nullagine geosyncline. The interaction of these elements of the Pre-Cambrian framework of the continent has been the chief cause controlling the later geological history of Australia.

Diary of Societies.

FRIDAY, JULY 25, TO *THURSDAY*, AUGUST 7.

GEOLOGISTS' ASSOCIATION.—Summer Field Meeting in the St. David's District, Pembrokeshire.

SATURDAY, AUGUST 2, TO *TUESDAY*, AUGUST 12.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section).—Summer Meeting in the Ruhr area and Switzerland.

CONGRESSES.

AUGUST 3 TO 9.

INTERNATIONAL CONGRESS FOR SEX RESEARCH (at House of British Medical Association).

Monday, Aug. 4.—Prof. F. A. E. Crew: Puberty and Maturity (Address). Papers relating to Puberty and Maturity.

Tuesday, Aug. 5.—Papers on the Biology of Testicular and Ovarian Function.

Wednesday, Aug. 6.—Papers on Hormone Therapy.

Thursday, Aug. 7.—Discussion on Psychology and Biology.

Friday, Aug. 8.—Papers on the Biological and Therapeutical Aspects of the Control of Human Fertility.

Among the papers to be communicated to the Sectional Meetings are The Aschheim-Zondek Test for Pregnancy (Prof. Aschheim), The Corpus Luteum Hormone (Dr. Clauberg); Biological Tests of the Female Hormone (Menformone) (Assistants from Prof. Laqueur's Institute); The Channels and Significance of Excretion of the Female Sex Hormone (Prof. R. T. Frank), The Male Sex Hormone (Prof. S. Loewe); Evidence for the Metabolic Basis of Sexuality (Dr. O. Riddle); Human Hybrids (Prof. C. G. Seligman).

AUGUST 4 TO 9.

INTERNATIONAL CONGRESS OF EXPERIMENTAL CYTOLOGY (in conjunction with the Anatomical Congress) (at Amsterdam).

AUGUST 5 TO 7.

IMPERIAL HORTICULTURAL CONFERENCE (to discuss the best methods of approach to horticultural problems and the technique involved) (at Royal Society of Arts).

Tuesday, Aug. 5, at 10 A.M.—Sir Robert Greig: Bureaux and their Work. The Director and Chief Officer of the Bureau: Discussion of the Work of the Imperial Bureau of Fruit Production and Future Lines of Development. This will be prefaced by a précis of the work already done.

At 11.30 A.M.—F. L. McDougall: Possible Development of Fruit Growing in the Empire from an Economic Point of View.

At 12.15.—J. L. Brown: The Evolution of the New Zealand Fruit Board.

Experiences of Horticultural Research—

At 2.30.—Dr. W. T. Macoun: In Canada:—(*a*) Centralised.

E. F. Palmer: (*b*) At an Unattached Station.

At 3.10.—Prof. A. C. D. Rivett: In Australia.

At 3.30.—Dr. B. Hahne: Horticultural Research in the Union of South Africa.

At 3.40.—W. G. Freeman: Tropical and Sub-tropical Fruit Industry. Difficulties Encountered and Lines of Attack.

At 4.15.—Sir Frederick Keeble: An Industrial Research Station.

Wednesday, Aug. 6, at 10 A.M.—Sir Daniel Hall: The Directions in which Experimentation is likely to be Valuable in Horticulture.

Field Experiments:—

At 10.45 A.M.—T. N. Hoblyn: The Adaptation of Modern Statistical Methods to Horticultural Conditions.

At 11.30 A.M.—Prof. E. E. Cheesman: Practicability of the Application of Statistical Method in the Case of Tropical and Sub-tropical and other Crops.

At 12.15.—F. J. Martin: Field Experiments in certain Tropical and Sub-tropical Crops in West Africa.

Application of Pure Sciences to Horticultural Problems under—Temperate Conditions:—

At 2.30.—Prof. B. T. P. Barker: Fruit Products and Associated Problems.

At 3.—Prof. V. H. Blackman: Some Physiological Considerations in Horticulture.

Tropical and Sub-tropical Conditions:—

At 3.30.—Dr. E. J. Maskell and Dr. T. G. Mason: Physiological Work in the Tropics. Some of the Problems with special reference to Cocoa, and some Possible Lines of Attack.

Soil and Climate Survey as a Basis for Fruit Research:—

At 4.—T. Wallace: Soil and Climate Survey as a Basis for Fruit Research.

T. Rigg: Soil Type and Manuring in Relation to Yield and Quality of Nelson Apples.

A. J. Prescott: Soil and Survey Work as a Basis for Fruit Production in Irrigated Areas.

At 4.30.—H. V. Taylor: Meteorology and Fruit Production: The British Scheme of Research.

Thursday, Aug. 7.—Progress of Fruit Storage Methods:—

At 9.30 A.M.—Dr. F. Kidd: A Survey of the Principal Fruit Storage and Transport Problems of the Empire to-day.

At 9.50 A.M.—T. Wallace: Factors influencing Storage Qualities of Fruits.

At 10.10 A.M.—Dr. A. J. Smith: Problems of Biological Engineering in the Cold Storage of Fruit.

At 10.30 A.M.—Dr. A. Horne: The Infection and Invasion of the Apple Fruit by Fungi in Relation to the Problem of Storage.

At 10.50 A.M.—Dr. D. Haynes: Chemical Change in Stored Apples: The Relation of the Time of Picking to the Chemical Composition and Storage-life of the Apple.

At 11.10 A.M.—Dr. L. P. McGuire and Dr. C. W. Wardlaw: Investigations of the Storage Behaviour of Bananas at the Low Temperature Station of the Imperial College of Tropical Agriculture, Trinidad.

At 11.30 A.M.—W. T. Hunter: Recent Progress in the Study of Johnathan Breakdown in U.S.A. and Canada.

At 11.50 A.M.—R. G. Tomkins: Biological Effects of Atmospheric Humidity.

At 12.10.—Meirion Thomas: Biochemical Study of Functional Diseases in Fruits.

Dr. B. T. Dickson and W. M. Carne: The Present Position of the Bitter Pit Problem in Australia.

R. Wheeler: Fruit Transport Problems in Canada.

E. A. Griffiths: Problems of Storage and Transport.

Prof. J. Young: Citrus Storage Investigations in Australia.

At 12.30.—F. A. Stockdale: Sources and Training of Future Horticultural Research Workers.

AUGUST 7 TO 15.

INTERNATIONAL HORTICULTURAL CONGRESS (in London).—*Papers to be read on Aug.* 8, 11, *and* 13:—

Prof. Priestley: Vegetative Reproduction from the Standpoint of Plant Anatomy.

Dr. Van der Lek: Anatomical Structure of Woody Plants in Relation to Vegetative Propagation.

Dr. R. Salaman: Vegetative Mutations.

Prof. E. Baur: Production of Mutations by External Stimulus.

Dr. F. E. Denny: The Excitation of Dormant Buds under External Influence.

John Innes Horticultural Institution: Graft Hybrids.

John Innes Horticultural Institution: Vegetative Production of Polyploids.

John Innes Horticultural Institution: Sterility.

G. E. Yerkes: Raising Root Stocks from Seed.

Government Control in Scientific Research.

THE nature and extent of government control in scientific research and its results, especially those which may involve monopoly in some form or other, has always been a matter of deep interest to all men of science. Indeed, its interest is not confined to them alone, for it is a question which vitally concerns the whole nation. It is scarcely too much to say that, to-day, when technical prowess and invention have reached a dominating position in connexion with national strength and well-being, this matter of government and science is among the most important of the present age.

Sir Ambrose Fleming discusses the question in the July issue of the *National Review* in an article entitled "Technical Inventions and Government Control". At the very outset he strikes the right note by exposing the absurdity and shallowness of the usual query—Of what use is it?—applied to any new advance in pure science. The classical example, often quoted but losing nothing by repetition, is afforded by Faraday's discovery in 1831 of induced currents, for which at that time no one would have paid him a shilling, though since worth untold millions. This example not only shows to what heights potential use may rise, but also indicates to what a remarkable degree new wants may be created by invention of means to satisfy them, a most interesting economic phenomenon.

A peculiar position arises, however, when the satisfaction of these wants leads, or may lead, to the establishment of a monopolistic industry. It was chiefly with the view of controlling and limiting monopoly that Government has intervened in highly technical industries, such as the electrical, often with very disastrous results. "The baby is put in handcuffs to prevent him becoming a burglar when he grows up." The nascent electric telegraph industry in Great Britain was bought up by the Government in 1868–69 at a cost of £10,000,000 from private interests and handed over to the Post Office to prevent monopolistic abuse; and so skilfully—accidental or otherwise—were the acts of transfer drawn that they covered all forms of electric communication, including wireless. It is open to question whether one form of monopoly has not been exchanged for another, possibly worse.

Sir Ambrose emphasises the need for generous and, so far as possible, intelligent treatment of

men of genius when they appear. It is preposterous that the work of such men, and its results in epoch-making discoveries—of which an infinite number are still possible and are hidden in the unknown—should be judged or in any way controlled by a single departmental head. Many such departmental heads lumped together might not make one good one. In the specific case of electric telegraphs and telephones, it is only fair to admit that State control has probably led to their greater extension into remote rural parts than might have been possible to private enterprise; but on the general question of government intervention it is of the utmost importance that there should be the closest and most effective co-ordination between State departments concerned and private enterprise and research.

An encouraging sign of the times and a step in the right direction is the organisation and work of the Department of Scientific and Industrial Research, to which Sir Ambrose Fleming pays a well-deserved tribute in the article to which we have referred. The part of the government is to encourage and stimulate research in the right direction (though who shall specify what is 'right direction' is perhaps difficult), and prevent exploitation of the public. Co-ordination is once more found to be the key to much blessedness.

H. J. Elwes, as Naturalist, Explorer, and Sportsman.

Memoirs of Travel, Sport and Natural History. By the late Henry John Elwes. Edited by Edward G. Hawke. With an Introduction by the Rt. Hon. Sir Herbert Maxwell, and a Chapter on Gardening by E. A. Bowles. Pp. 317+18 plates. (London: Ernest Benn, Ltd., 1930.) 21*s*. net.

IN describing his journeys in Sikkim, Elwes writes that Claude White's "Sikkim and Bhutan" forms a fitting supplement to Hooker's "Himalayan Journals". A perusal of parts of these memoirs, nearly a third of which are devoted to India and journeys in Sikkim and round Darjeeling, will readily show to the initiated that Elwes's reminiscences and experiences cover a very valuable period of years between the day of Hooker and that of White in this region. Before treating of this aspect a few general remarks will be necessary on this remarkable and fascinating book. It is difficult to recall any book of quite its type published during the last, perhaps, forty years. If the knowledgeable reader is left with one regret it will probably be that Elwes did not commence the publication of the memoirs during his lifetime, and give them to us in two or three volumes.

Sir Herbert Maxwell, a contemporary of Elwes at Eton, has written a most appreciative and informative introduction to the book; and Mr. E. A. Bowles, in a last chapter entitled "Gardening and Horticulture", embodies personal impressions and recollections of Elwes and his botanical and horticultural work, with some descriptions of the remarkable gardens brought into being by Elwes at his Gloucestershire home, Colesborne.

Anything approaching a detailed review of the memoirs is out of the question. The book well reflects the personality of Elwes himself; it is inexhaustible. In order, however, to render the following remarks intelligible it must be understood that apart from sport provided by rifle and gun, in the use of both of which he was expert, the author started early in life collecting birds. His first expeditions, undertaken as a young man, with the chief object of increasing his knowledge and his collections of birds, were made in the Hebrides (1865–68) and Turkey—Macedonia (1869). These were made during the period he served in the Scots Guards. Later his main interest centred in butterflies and moths, although he never gave up bird-collecting—and lastly, after some twenty years during which Lepidoptera were his chief interest, although he also collected both birds and plants, he definitely concentrated his attention chiefly on plants with the most valuable results. For, as his numerous friends were well aware and his book will disclose unerringly to future generations, this man was possessed of immense energy, powers of observation of no mean order, which he cultivated to a very high pitch, and a shrewd mind. These attributes enabled him, as his experience grew with his varied voyages and the management of his own estates, to deduce reasons, sum up arguments, and present solutions of value. He contributed many valuable papers dealing with his collections to scientific societies.

Sir Herbert Maxwell says it was enthusiasm, aroused by reading Hooker's "Himalayan Journals", which first took Elwes to India in 1870. He landed at Madras in January from the old P. and O. *Mooltan*. Two brother officers of the Scots Guards joined him, and their chief object was to kill elephants, a sport which after a brief experience Elwes did not think much of, much preferring "stalks after stags, elk, and chamois". From Madras they sailed to Calcutta. From here Elwes had wished to explore the wild Mishmi Hills on

the north-east frontier of Assam, the flora and fauna of which were unknown. Owing to the recent murder of missionaries the Viceroy, Lord Mayo, would not assent to the suggestion and Elwes went north to Siliguri, at the foot of the Himalaya, where he says there was even then a fair dâk bungalow. There was to be a big tiger-shooting party in the Jalpaiguri Duars and Cooch Behar jungles. To this fortunate fact we owe Elwes's eye picture of this country as it was sixty years ago, and about twenty-two years after Hooker's visit and description. What is now a great stretch of tea-gardens was then dense forest and grass jungle on both sides of the Tista River, with a few scattered tea-gardens only; the country contained numerous rhinoceroses, elephants, and tigers. Before the end of the century the rhinoceros had been exterminated in these parts and elephants did not come so far west from the Assam border. Elwes comments on the magnificent forest of sal he saw stretching out from the foot of the hills and climbing up some way, to be replaced by sub-tropical species up at Kurseong (about 4500 ft.). There was no railway then; and later Elwes was as much put out by the spoiling of the beauty when the railway was carried up to Darjeeling, as I was astonished when (in 1925) I went up there from Siliguri by motor-car!

Elwes lost his heart to Sikkim on his first visit in 1870. Finding Darjeeling too muggy and misty in the rains for his liking and purposes, he descended to a tea-garden named Ging, managed by Mr. Macdonald. This was in the early days of tea-planting in that region and many ignorant mistakes had been made and much money wasted. With the assistance of Macdonald, Elwes bought neighbouring land and commenced a garden of his own under Macdonald's supervision. Elwes said later that he had never made a better investment than in that garden. During the following sixteen years he made four visits to Darjeeling and the garden—but they were to some extent mere pretexts upon which to hang one of his journeys out into his loved Sikkim hills; though the last was connected with the proposed but abortive Tibet Embassy of 1886. But this time he got up to the Rishi-la and practically explored a new route to the Tibet boundary.

I spent the best part of the last three years of last century in Sikkim and on the Darjeeling side. The Tista valley, roadless in 1870, the Rangit valley, and the roads and paths up into the Sikkim hills, the wonderful views and the extraordinary tropical, semi-tropical, and sub-temperate flora and fauna were my companions on many solitary journeys for weeks at a time; and oft did I ride with a dripping jacket, as Elwes had done, through the magnificent uncanny forests, the trunks of the trees coated with long beards of grey moss and lichen.

It is with this later knowledge of the progress and development which have taken place in the region that it is possible to realise to the full the very great value of the chapters of Elwes's memoirs which are devoted to Darjeeling, to a visit to the Singalela Range dividing Sikkim from Nepal on the west, and above all to his four journeys into Sikkim, the first made with the late Dr. W. T. Blanford, director of the Geological Survey. They must have been a curious couple, for Elwes was but twenty-four years old, with his ideas quite unformed—but he recognises how much he learnt from and owed to his older and skilled scientific companion. The well-known names which cross his pages are in themselves a remarkable testimony to Elwes's wonderful life. For they are names well known to officers who served out east and to those connected with Kew and Edinburgh Botanic Gardens; but which were mostly quite unknown to men—squires of the social county position of Elwes. Hooker, Thiselton Dyer, and Prain, at Kew; Bayley Balfour at Edinburgh; Anderson at the gardens in Calcutta; C. B. Clarke at the Cinchona Garden at Mongphu, followed by Gammie; F. D. Godman, A. O. Hume, Godwin Austen, Hampson, Knyvett, de Niceville, Mandelli, Atkinson, Woolly-Dod, and a host of others.

In none of the journeys Elwes paid to other parts of the world did he find any country to outvie the Tista Valley and the Sikkim Hills for scenery and variety in flora and fauna. The great fascination which this region exerted over him, in spite of its drawbacks at the lower elevations of damp heat and innumerable leeches, is comprehensible to the naturalist. It was the first part of the Himalaya I visited, and subsequent journeys all over India and parts of Burma never showed me anything to compare with Sikkim.

During these visits Elwes collected and sent home or brought back valuable collections of birds, butterflies, and moths, many now in the national collections; and also introduced numbers of plants and bulbs and orchids into England. His own gardens and greenhouses at Colesborne (in spite of the thin poor soil of the region limiting his possibilities) gradually included a wonderful collection of plants, orchids and rhododendrons being perhaps his favourites. In addition to his

four visits to Sikkim he made a last journey to India to visit Nepal in 1913–14, being then aged sixty-seven, and his account of the trip shows that his keenness and his powers of observation were as great as ever.

Apart from India, Elwes made an adventurous trip with a companion to the Altai Mountains in 1898 and shot *Ovis ammon*, but, as he relates, he was keener on collecting. He twice went to North America (1888 and 1895) and on each tour did a certain amount of collecting. Another interesting journey was undertaken to Chile (1901–2) with three main objects in view—as he says: (1) To gain some idea of the peculiar conditions which make the fauna and flora of Chile so interesting; (2) to collect as many as possible of the Lepidoptera "which had never been studied by a competent entomologist"; (3) "I wished to learn something about the very beautiful plants of Chile which we grow in gardens and of whose habitat we know but little, and to introduce to cultivation the terrestial orchids which are such a marked feature in the flora of the country". There speaks the man—and this is his life's note. He always had quite clearly conceived ideas before he started on a trip—and he was amazingly successful as a result.

One of not the least interesting of Elwes's journeys was the one made in 1911–12 to the Malay Peninsula, Java, and Formosa. The similarity of parts of the latter to Sikkim appears to have struck Elwes forcibly, but it is impossible to follow him through these interesting countries. Two points may be made. His study and comparison of the cinchona-growing in Java with the Indian gardens—Java exports the largest amount of quinine, *C. Ledgeriana* being the best species for sulphate production. His remarks on the growth of rubber in Malaya, and, as an old tea planter, the advice he tendered—advice as true to-day as it has been any time during the last century in the British Empire—are worth recording: "I could not help thinking that if rubber planters were not so anxious to get a large area cleared at once, it would probably pay better in the end to leave all the poorer patches of land in forest as a shelter to the rubber (*Hevea*)". In the hills this would prevent the rapid erosion and loss of valuable humus, etc., which total clearance gives rise to; whereas in the plains great pure blocks of one species of tree would be broken up and therefore suffer less from insects and fungus pests.

The last four chapters are devoted to home—two discussing problems of rural life and farming, with the great knowledge and shrewdness of a fine intellect; the others devoted to a description of how his great book "The Trees of Great Britain" came to be written in collaboration with Prof. A. Henry; and a review of the Committee's Report on the Deer Forests of Scotland (1922), written in the year of his death.

For the sportsman not the least interesting and remarkable parts of these fine memoirs are the chapters devoted to sport. For twenty years (1891–1911) Elwes rented shoots in Norway, where he stalked the elk, bear, and reindeer; he also shot wild boar in the Ardennes and rented a shoot in the Austrian Alps where the quarry was red deer, chamois, and roe deer. These chapters, which cover a considerable period of shooting years, would render any book remarkable, not only for the interesting accounts of the various animals and the methods employed in hunting them, but also owing to the care with which Elwes describes the country and the natural history of the locality visited.

I feel confident that this book is destined to become a classic; higher praise no book can achieve.

E. P. STEBBING.

Foundations of Silviculture.

Foundations of Silviculture upon an Ecological Basis. By Prof. James W. Toumay. Vol. 1. Pp. xxv+438. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1928.) 20*s*. net.

IN this manual, Prof. Toumey, of Yale University, deals with silviculture from the point of view of the forests of the United States, a country which, he correctly says, owing to its vast size and diverse character, imposes inevitable limitations. But this is not the only point in which Prof. Toumey's work differs from the usual type of silvicultural manual. He writes:

"In the evolution of the subject, the vast body of accumulated facts which gradually came into being, relating to trees and their environment, though useful in silvicultural practice, lacked for a long time the following basic concept: Forest vegetation is composed of plant communities or units of vegetation, developed and arranged in accordance with definite biological laws and is not an aggregation of trees and other plants brought together by chance." . . . "Foundations of silviculture as we conceive it to-day is not an outgrowth of plant ecology, but rather plant ecology is an outgrowth of it. When biologists took their investigations of the relation of plant to the environment from the laboratory to the field, they found

the silviculturist already there with the accumulated facts of a century of field work."

The latter allusion is to the work of men like Cotta, Hartig, Köenig, and Pfeil. But in the preceding century these latter had had forerunners in Duhamel du Monceau in France and Euderlin in Germany. This work had for its chief basis the relation of soil factors to forest vegetation, studies which were continued in the later works of Mayr, Duesberg, Wagner, Reuss, Dittmar, and others. In these works the authors apply fundamental sciences such as biology, physics, and chemistry to the theory of silvicultural practice.

Forest experiment stations were established in several countries from 1861, and though the results attained have not perhaps reached the somewhat sanguine hopes placed in them, certain useful data have been arrived at.

It is perhaps in its connexion with ecology that this manual differs from many of its predecessors. Haeckel, in 1866, defined ecology as the science treating of the reciprocal relations of organisms and the external world. Says Prof. Toumey:

"Until recent times, what is now conceived as ecology was included under biology. Biology is a general term including both botany and zoology, and ecology is a part of each. Although biologists have for many years been concerned with the relation of plants to their environment, the term plant ecology has come into use within comparatively recent times. As a science, it is a branch of botany, which is concerned with the relations of the individual plant, the species and the plant community to the site. It has its roots firmly anchored in the basic principles of physics, chemistry, physiography, geology, and meteorology."

This recognition is not only of interest but also of considerable importance to the future value of the large amount of silvicultural research work awaiting the forester in many parts of the world. But when dealing with a consideration of silviculture proper in a forestry manual, it becomes necessary to consider the limits to which a treatment of the subject should be set.

In the manual in question, the author divides his subject into three parts: (1) the site factors; (2) the forest vegetation; (3) the methods of investigating the site factors and the forest vegetation and their relation one to the other. Only parts 1 and 2 are treated of in the volume under review, part 3 appearing in a later volume. Out of 423 pages in this first volume, some 250 are devoted to the site factors which, after a chapter on definitions, are treated of under climatic factors, physiographic factors, biotic factors, and the reaction of forest vegetation on the site factors.

The author deals with these matters in the greatest detail and with admirable lucidity; for example, the sections on light effects, intensity, etc., are of absorbing interest: but the question thrusts itself forward— Is the detailed treatment of such matters in its proper place in a manual on silviculture? Should we not recognise the fact that this subject has now become so broad that it requires an introductory manual dealing with such matters as are considered in Part 1 above and including sections of Part 2 treating of the origin and development of forest communities, succession, and so forth. The word ecology is a new one. It should prove possible to find a satisfactory term for the considerable introductory matter which now leads up to silviculture proper – for silviculture, both in derivation of the word and its practice, belongs of right to the practical executive forester working out in the field.

This being said, Prof. Toumey is to be congratulated on a remarkable piece of work. His second volume will be awaited with considerable interest.

Coal Carbonisation.

Coal Carbonisation. By R. Wigginton. (Industrial Chemistry Series.) Pp. x + 287. (London: Baillière, Tindall and Cox, 1929.) 21*s.* net.

"BUT for its obvious importance, no one would interest himself in the action of heat upon coal." This is surely a strange doctrine, for scientific men do study many things out of mere human curiosity. Mr. Wigginton presumably means that the problem is so involved as to discourage inquiry. Even the action of heat, he points out, on so simple a compound as ammonia has provoked a mass of research, collated in Chapter v. How much more complex will be the action of heat upon coal, "a mixture of altered plant tissues, the original plants being composed of substances chiefly of unknown constitution".

The book is concerned with this question of the action of heat on coal, first historically (Chapters i. and ii.), then with the science of the subject (Chapter iii.), as it has developed from modern laboratory work. Chapter iv. treats of coal gas manufacture and purification, Chapters v. and vi. of the by-products ammonia and tar, while the last chapter is devoted to the formation and properties of coke.

The book is not intended to be a manual for industrial practice, which is treated only in broad

outline, illustrated by simple diagrammatic sketches. The value of the book is due rather to the fact that it gives a conspectus of the subject in the light of recent laboratory studies. Anyone desiring to get to grips with the science of carbonisation will scarcely find a better channel of access, for the author is evidently familiar with the British, European, and American investigations of the last decade. The collection of information on the decomposition of ammonia and hydrocarbons at high temperatures is valuable—especially the recent work on pyrolysis carried out at Sheffield. On p. 42 he says: "At the time of writing, the high (though declining) price obtainable for creosote oil is having a considerable bearing on the economics of the process". If he were writing that sentence to-day, he would have to substitute 'low' for 'high' and say that creosote is such a drug on the market as to make its disposal a real problem. Ammonia has also ceased to be a considerable asset, and indeed sometimes is a charge on the process. Nothing could indicate better the need for caution in placing any high value on the gain obtainable from by-products of carbonisation. The sale of gas according to heating value dates from 1920—not 1922 (p. 132). The description of the manner of removing naphthalene from gas (p. 138) does not suggest the continuous process now in use. On p. 173, 'undecomposed' steam should be added as an additional source of water in gas liquor from vertical gas retorts, which constitute more than half the plant in use to-day in British gasworks.

The publisher invites criticism at times. On p. 104 he has not done the author justice in reproducing curves on so small a scale as to make them difficult to read. Again, the price is the highest in the whole "Industrial Chemistry Series", while books of similar size are priced at 10*s*. 6*d*. upwards. The number of guineas which young students can afford is limited, and this is a book which one would like to recommend them to buy.

H. J. H.

Geography and Regional Studies.

Studies in Regional Consciousness and Environment. Essays presented to Prof. H. J. Fleure. Edited by Iorwerth C. Peate. Pp. xii + 220 + 14 plates. (London: Oxford University Press, 1930.) 21*s*. net.

By a curious coincidence, the publication of this volume of essays presented to Prof. Fleure by a group of former students on the completion of his twenty-five years at Aberystwyth coincides with the announcement of his departure for Manchester. Few tributes could be more eloquent, few more acceptable, than such an acknowledgment of the inspiration afforded by academic leadership. At first sight the essays seem extraordinarily diverse, ranging from geology to helminthology, economic history, and French politics, and in area from Wales to Natal and the Great Barrier Reef. But the whole collection is united in that it is concerned with the world as the environment of the central figure—man—and typifies the science for which Prof. Fleure has stood for more than a quarter of a century—the science of modern geography.

Amongst the more purely geographical researches included are Miss R. M. Fleming's "Outline of some Factors in the Development of Russia"—a valuable summary which incorporates a considerable amount of material formerly only available in Russian; Miss F. F. Laidler's study of the limits of certain cultivated plants in Spain—an important contribution to the solution of the vexed problem of how far Spain can be regarded as a 'Mediterranean' country; and Mr. E. E. Evans's geographical study of the Pyrenees as a barrier to mankind. The editor of the volume, Mr. Iorwerth C. Peate, contributes an account of the old Welsh wood-turning industry; Wales also figures in a geological contribution by Prof. W. J. Pugh and a study of miners' phthisis in Cardiganshire by Mr. E. G. Bowen.

Miss H. A. Wilcox has attempted to throw light on the former distribution of natural vegetation in southern England—a subject fraught with difficulty but of the utmost importance to the prehistorian. Mr. S. J. Jones deals with the distribution of perforated stone axes in Europe, Mr. R. A. Pelham with the trade of the Cinque Ports in 1307–8, Miss S. Harris with field systems in Guernsey. Mr. H. Hauck deals with the influence of geographical factors on the French elections of 1928. His maps emphasise the fact that the rich cattle-rearing and cultivated districts support the right wing party, the peasant owners of small farms maintain the radical faction, whilst the extreme left receives its main support from urban and industrial centres. It is interesting to notice how closely his conclusions would apply to Great Britain.

The last essay in the volume strikes a different note, giving a delightful sidelight on daily life and work with such an expedition as that to the Great Barrier Reef.

L. D. S.

Our Bookshelf.

Australian Rain-Forest Trees : excluding the Species confined to the Tropics. By W. D. Francis. Pp. xii + 347. (Melbourne : Council for Scientific and Industrial Research, 1929.) 10s.

ALTHOUGH this book is primarily intended for the Australian forester and botanist, it provides a wealth of information about the trees of the rain-forest of eastern Australia which renders it a useful work of reference. The outstanding feature is that the descriptions are drawn up by a botanist who is equally familiar with his specimens as trees in the forest and as herbarium material.

The practical side of the work is further enhanced by an artificial key to the trees described, which has been worked out and drawn up by the author in the field. Keys of this nature are difficult to make as a rule, but undoubtedly they are appreciated more by the forester, who often finds difficulties in working in the field with keys prepared from herbarium material only and worked out on a phylogenetic basis. As the systematic enumeration of the species is according to Engler and Prantl, it would have been helpful had page references been inserted against the names of the species where they occur in this artificial key. The book itself is not a convenient size for field work (9 in. × 6 in.) and it would be advisable to issue the artificial key in pamphlet form so that its usefulness can be extended.

The book is profusely illustrated by plates which are given generally in pairs—one plate showing the lower part of the bole of each trunk, the nature of the bark, the base of the tree, and the character of the surroundings; the other, a more detailed view of leaves, flowers, and fruit.

This is a very good example of a work which cannot have more than a local—though a very wide local—interest and application. So much work of this nature is never able to be published because it cannot be considered to be an economic proposition. It is very gratifying, therefore, to note that Mr. Francis was able to secure official publication through the recommendation of Mr. Lane-Poole, Inspector-General of Forests. This is the second publication by the Commonwealth Government under the scheme for assisting the publication of work carried out by Australian scientific workers which is not likely to prove financially remunerative and therefore is unattractive to commercial publishing houses.

Marriage, Past, Present and Future : an Outline of the History and Development of Human Sexual Relationships. By Ralph de Pomerai. Pp. xvii + 370. (London : Constable and Co., Ltd., 1930.) 15s. net.

MR. DE POMERAI's book is a welcome and opportune addition to the literature on marriage, even though Prof. Westermarck has published within the last few years a revised and enlarged edition as well as an abridgment of his classical work on the subject. The author of the present book holds that both Westermarck and Letourneau, having written exclusively from the viewpoint of the family and regarded procreation as the sole or highest function served by matrimony, have paid insufficient attention to the urge of the gregarious. In other words, he suggests that they have fallen out of date owing to the institution and spread of 'companionate' unions and the changed ideals and ideas which they imply. Further, there has to be taken into account the effect of current psychological theory in relation to sexual activity and repression.

The reader will here find the evidence to be collected from primitive peoples reviewed from a new point of view ; the practices of the present day, both orthodox and those regarded by some as unorthodox, are analysed; and the probable course of future development is sketched in the light of tendencies here revealed. Much of the book is naturally of a highly controversial character. The validity of the argument, in fact, depends upon whether its viewpoint rests upon what is merely a passing phase or on a development which is to be a permanent directional factor in the future evolution of society. This is too large a subject for discussion here, much as Mr. de Pomerai invites it. It may be pointed out, however, that the modern attitude towards marriage and sex appears to give too great weight to factors which are secondary to the main biological purpose of society and of sexual relations.

Gnetales. By the late Prof. H. H. W. Pearson. (Cambridge Botanical Handbooks.) Pp. vii + 194 + 4 plates. (Cambridge : At the University Press, 1929.) 18s. net.

THE class Gnetales is unique among seed-bearing plants in the habit and habitat diversity of its members and in the use made of it by those interested in phylogenetic hypothesis. The appearance of a monograph by the late Prof. H. H. W. Pearson is, therefore, a matter of considerable importance. The manuscript was completed and prepared for printing by Mrs. Thoday, who has added valuable notes and is largely responsible for the final theoretical chapter.

The first chapter summarises the habit, distribution, ecology, and taxonomy of the three genera *Ephedra*, *Gnetum*, and *Welwitschia* ; the second gives details of their vegetative morphology and anatomy ; the third considers their inflorescence and flower structure ; and the fourth deals very fully with their reproduction. A frontispiece of the author, three plates, and 89 figures illustrate the book.

The interrelationships of the three genera remain obscure, and proof that they are of near affinity is lacking. The somewhat diverse views held as to the natural position of the Gnetales most often agree in placing the group in the vicinity of the top of the Gymnosperms and the bottom of the Angiosperms. The Angiosperm characters have been emphasised by recent writers, and Pearson agreed "that there must be a Gnetalean-Angiosperm alliance" but probably not a direct one. A hypothesis is outlined which derives the

Angiosperm embryo-sac from a primitive form the essential characters of which are preserved in *Gnetum*, the evolutionary tendency being towards a shortening of that portion of the life-cycle which lies between the macrospore mother-cell and the functional gamete. W. B. T.

Œuvres d'Émile Godlewski, père. Publiées par Ladislas Vorbrodt. Vol. 1 (1870–90). Pp. viii + 599. (Cracovie: Académie Polonaise des Sciences et des Lettres, 1930.)

THE Polish Academy of Science and Letters is publishing in three volumes, of which the first has already appeared, the collected work of Émile Godlewski, the veteran plant physiologist who celebrated his eightieth anniversary in 1927. This first volume contains an early paper on the dependence of the amount of oxygen disengaged from leaves upon the carbon dioxide content of the air, which was carried out by the author in Sach's laboratories with apparatus previously used by Pfeffer, then also working at Würzburg, as were also the English botanists Vines and Francis Darwin.

The volume contains papers written prior to 1890; they are published usually in the language in which they originally appeared, but a few of the Polish papers are translated for the first time (into French). These papers alone are sufficient to show what a valuable influence Prof. Godlewski must have had upon the development of the biological sciences in relation to agriculture during his tenure, first of the chair of botany at the School of Agriculture in Doblany (1878) and then of the chair of agricultural chemistry at Cracow, where he was also in charge of the subject of vegetable physiology (1891–1919). Still vigorous upon the expiry of his post under the regulations for superannuation, Prof. Godlewski then accepted the direction of the agricultural section of the Institute of Rural Economy just established at Pulawy.

50 Jahre Kältetechnik 1879–1929: Geschichte der Gesellschaft für Linde's Eismaschinen A.-G., Wiesbaden. Pp. iv + 192 + 6 Tafeln. (Wiesbaden: Gesellschaft für Linde's Eismaschinen A.-G., 1929.)

THIS well-illustrated volume has been issued in commemoration of the jubilee of the foundation of the Linde company in 1879. It contains a short life of Prof. Carl von Linde, the founder, an account of his early work on refrigeration and on the use of the Joule-Thomson cooling as a means of liquefying gases on an industrial scale, and a history of the development of the company and its offshoots up to the present time.

Von Linde was born in southern Bavaria in 1842, a son of the manse. After education at the local Gymnasium, he spent three years at Zurich polytechnic and after two more years in locomotive works he was in 1866 appointed to the technical staff of the Krauss locomotive works at Munich. In 1868 he became additional professor and in 1872 ordinary professor of engineering in the newly founded technical school at Munich. Here he introduced such improvements in the theory of refrigerating machines that in 1879 the Linde company was formed with works at Wiesbaden to manufacture machines on his system. In 1892 he returned to Munich and lectured on refrigerating machines there until 1910. In 1895 he succeeded in liquefying air by the Joule-Thomson effect and this led to the liquefaction of other gases and the establishment of Section B of the company for the manufacture of machines for industrial liquefaction and fractionation of mixtures of gases.

Coleridge: the Sublime Somnambulist. By John Charpentier. Translated by M. V. Nugent. Pp. x + 332. (London: Constable and Co., Ltd., 1929.) 15s. net.

THIS is certainly a beautiful and inspiring book, in spite of a certain heaviness of style due partly to excessive faithfulness in the translation. It is remarkable how many English worthies are finding their best interpreters in Frenchmen. M. Charpentier does not compete with the vivacity of M. André Maurois in his lives of Shelley, Disraeli, and Byron, but he is a much more profound and sympathetic student. He judges very fairly the philosophic attainment of Coleridge, not rating it high; he is enthusiastic about the best in his poetry and he gives a penetrating and convincing study of his personality. The fight with opium, the devastating effects of the drug and the noble and finally successful struggle to overcome it, with the help of Dr. Gillman, could scarcely be better described, and will be to many readers the most interesting part of the book. But they should not resist the fascination of M. Charpentier's picture of the 'old man eloquent' in his last stages at Highgate. He was essentially good and would not have seemed old, had it not been for the ravages of his vice. He was but sixty-two when he died, and those who care for his memory, a number likely to be increased by this book, would do well to see that his tomb in the crypt at Highgate School is more reverently treated than it was when we last visited it. F. S. M.

Experimental Optics. By Prof Albert F. Wagner. Pp. xii + 203. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1929.) 16s. net.

THE course of optics outlined here is one which has been developed for an advanced class at the postgraduate school of the United States Naval Academy. Some ninety experiments are described, in general of an advanced type and requiring more elaborate apparatus than is found in most teaching laboratories in Great Britain. Its value for general purposes would have been increased considerably if more photographs and perspective diagrams of apparatus had been given, although those present are excellent. In spite of these minor defects, which are indeed only apparent when it is put to a use other than that for which it was originally intended, the book should be of much value as a work of reference for technical students and the more advanced degree classes. Prof. Wagner insists upon the importance of geometrical optics.

Single Collisions of Electrons in Nitrogen.

IN some recent experiments, I have measured the energy losses suffered by electrons of initially homogeneous speed in passing through nitrogen, the pressure of which was so chosen that no appreciable amount of multiple collisions should occur. The method consists in accelerating electrons from the hot cathode C into the field-free space bounded by A and B, where the collisions take place (Fig. 1). Those electrons which have not been deflected appreciably from the original direction of travel proceed through the perforated centre of B and through the narrow slit S_1 enter the box D, where their speed is measured by means of a deflecting electric field between E and F and a box collector G, placed immediately behind the exit slit S_2.

Hughes, Rojansky, and McMillen[1] have shown that in such a cylindrical deflection condenser refocusing of the electron paths takes place for a mean deflection of 127° 17′, which is the distance along the arc from S_1 to S_2. Pure nitrogen is supplied through an artificial leak and, having passed the collision chamber, is pumped away to the right of S_1 by a large steel diffusion pump. Sensitive compensation devices enable bombarding and deflecting voltage to be checked and adjusted with a high degree of accuracy. A number of curves at constant bombarding voltage were taken by varying the deflecting voltage in small steps. In most experiments, however, the deflecting field was kept fixed, and the different parts of the electron distribution curve were measured in turn by applying an adjustable accelerating voltage between B and S_1. Bombarding voltages ranged from some 80 to about 600 volts; pressures of 1–4 × 10^{-2} mm. were used.

The distribution curves obtained with both methods of measurement exhibit a strong and sharp peak due to electrons which have retained the whole of their

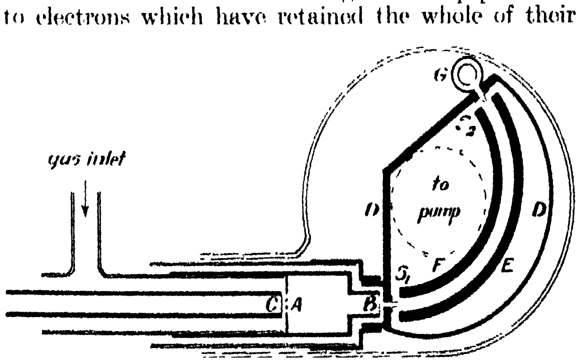

FIG. 1.

energy. Close to this peak, on the side of lower velocities, there are several small maxima in addition to a continuous distribution, which is rapidly approaching zero at greater distances from the primary peak. Fig. 2 shows the general appearance of the curve corresponding to energy losses of 0-30 volts. Part of the inelastic collisions responsible for this curve take place at the edges of S_1 and of the holes in B (possibly also to a small extent in A). From a comparison of curves with a high vacuum in the chamber and with different pressures of nitrogen it is usually possible to distinguish the effects of such collisions from those produced by impacts with molecules of the gas.

The volt equivalents of the energy losses indicated by the maxima in the distribution curves are tabu-

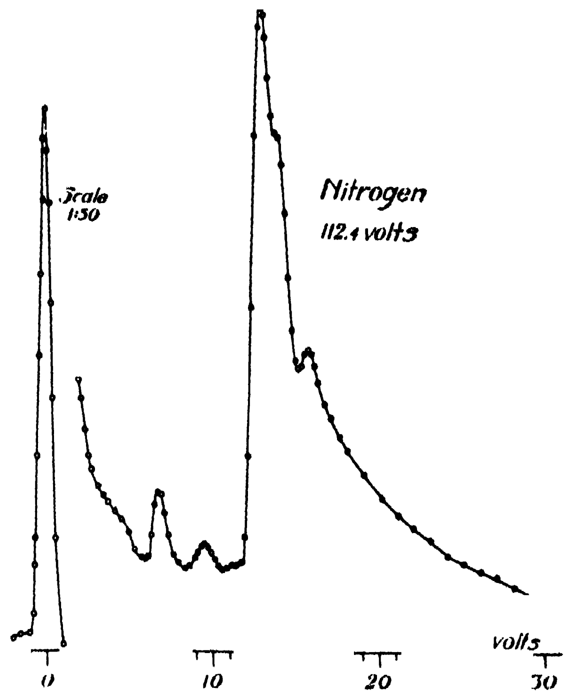

FIG. 2.

lated below, together with the number of independent determinations and the average error in each single determination.

	V_1	V_2	V_3		V_5	V_6	V_7
No. of determ.	22	23	9	24	19	23	
Average error		0·17	0·28	0·13			
Maximum	6·64	9·25	10·86	12·78	13·93	15·82	18·03
Interpretation	Pt 6·5 Cu 6·9	a (2) 8·91 a (3) 9·11 a (4) 9·31		b 12·52 b' 12·79 c 12·87-8			

V_1 must be attributed to impacts with the electrodes. In fact, I have previously been able to show[2] that there is frequently a loss of 6·5 volts with platinum —B is a platinum foil—and of 6·9 volts with copper (copper slits). Of the rest, at least V_2, V_4, V_5, and V_6 appear to belong to collisions in the gas.

By far the most conspicuous one of these is V_4. Energy losses of this magnitude have been observed by Langmuir and Jones,[3] and by Harnwell,[4] in connexion with other work. The value of 12·78 volts is in excellent agreement with a transition from the X level of zero vibration for the normal molecule to the group of electronic levels b, b', c, found by Birge and Hopfield.[5] The 0 level of the lower a state is only 8·51 volts above the normal level in the non-vibrating state. From the known emission intensities of this band, however, it appears that the most probable jump from the latter level to the a state would be to a level of vibrational number 3 or 4. If V_2 is attributed to such transitions, the observed value of 9·25 volts would, in fact, indicate a most probable end level of vibrational number 3 or 4. The considerable width of the 9·25 volts peak is consistent with this interpretation. The other maxima have not been correlated with any known spectroscopic levels at present.

One of the chief objects of this investigation was to look for evidence of excitation processes pertaining

to the K-level of nitrogen. Since $K = 388\cdot6$ volts for the nitrogen atom, these processes would be expected to give rise to a maximum in the region 370-410 volts below the primary peak. However, a careful search over this region with bombarding voltages as high as 590 volts failed to reveal any features of the kind expected. To give an idea of the sensitiveness of this test, it may be mentioned that in one case (bombarding voltage 540 volts) the total electron current received by the collector in the region in question produced a steady deflection of the shunted electrometer amounting to 3 mm. of the scale. A maximum of 2 mm. could not possibly have escaped detection. The $V_{4'5}$ maximum, however, was 9·5 metres on this scale and the primary peak 148 metres! Although it must be remembered that only nearly undeflected electrons are counted in these experiments, and that the chance for a colliding electron to continue in the same direction after the event could diminish as the amount of energy lost becomes considerable, one can scarcely but infer from this result that the probability that the electron will disturb a K-electron is small compared with that of the displacement of an outer electron.

The Dissociation Theory of Solution.

IT is now forty-three years since the electrolytic dissociation theory was proposed by Arrhenius in 1887, to account for the changes in the physical properties of solutions caused by electrolytes, which had compelled Van 't Hoff to introduce the coefficient i into the gas equation

$$PV = RT.$$

Impressed with the view that the osmotic pressure, depression of the freezing point, diminution of vapour pressure, etc., of solutions are functions only of the number of dissolved particles, Arrhenuius concluded that 'electrolytes' must contain a greater number of particles, which could only be derived from the dissociation of the solute. By choosing the 'dissociation' of each substance to fit the observed values the theory could easily be made to account for such effects. It can now be shown that the assumption involved is incorrect.

In a series of papers on the molecular theory of solution, and on the vapour pressure of liquids, in the *Philosophical Magazine* (**38**, 696, 1919; **44**, 897, 1922; **48**, 936, 1924; **50**, 1147, 1925; and seventh Ser., **10**, 160, 1930), I have shown that the vapour pressure of a liquid is produced by the particles that approach the surface with sufficient heat energy to enable them to overcome the attraction of the liquid and escape into the vapour. The vapour pressure is therefore a function of molecular attraction, volume, and motion only. It is expressed by the formula

$$p = 81\cdot84 \frac{T\lambda}{A\phi} e^{-\frac{9\cdot665SMA^{2/3}}{T\delta\lambda^2\rho}} \qquad (1)$$

in which T is the absolute temperature, λ the ratio of the total average velocity of the molecules in the liquid in the given circumstances to that in a perfect gas, A is the actual state of aggregation of the molecules in the given liquid, ϕ its co-volume, S its surface tension, M its molecular weight, $\delta \times 10^{-8}$ the nearest distance of approach of the centres of the molecules, and ρ the density of the liquid. In this formula the factor λ should be specially mentioned because its introduction amounts to a denial of the principle of the equipartition of energy. As we are considering the motion of molecules in a liquid, which are subject to the action of the tremendous forces that produce the cohesion of the medium, we are compelled to admit that their velocities cannot be the same as those of the particles in a perfect gas at the same temperature. The factor λ represents the ratio of the most probable speed of the molecules in the liquid to that in a perfect gas, and is a function of the cohesion, K, of the medium.

If this expression is extended to cover solutions of non-volatile solutes, it becomes

$$p = 81\cdot84 \frac{M_2 w_1 T\lambda}{(AM_1 w_2 + M_2 w_1)\phi} \times e^{-\frac{9\cdot665A^{2/3}M_1S_1^{1/2}\{S_1^{1/2}\rho_{12}w_1(\delta_2^{1/2} - A^{1/6}\delta_1^{1/2}) + S_{12}^{1/2}\rho_1(w_1+w_2)A^{1/6}\delta_1^{1/2}\}}{T\delta_1\delta_2^{1/2}\lambda^2\rho_1(w_1+w_2)}},$$

in which w is the weight of solute or solvent, the subscripts relating to solvent and solute respectively, and gives values for salt solutions in accordance with observation.

It follows that the vapour pressure of salt solutions is determined by the attractions, volumes, and motions of the particles only. When a salt is dissolved in water, the cohesion of the liquid is increased on account of the greater cohesion of the salt particles. In the case of a salt solution, therefore, as distinct from that of an inert substance that does not increase the cohesion of the liquid medium, the vapour pressure is diminished by the greater attraction to be overcome by the escaping molecules, as well as by the diminution in the number of particles of solvent present in unit volume of the liquid. That is to say, in an aqueous solution of urea, for example, the vapour pressure is less than that of pure water, merely because there are less water particles present in unit volume, but in a solution of common salt the fewer water particles must also overcome a greater attraction on the part of the solution before they can escape into the vapour. Therefore, the fundamental assumption of the dissociation theory, that the diminution of vapour pressure is proportional only to the number of solute particles present, is incorrect. The vapour pressure is determined also by the cohesion and volume of the solute particles. Instead of choosing the 'dissociation' to fit the observed properties, it is now possible to calculate the properties of solutions from the attractions and volumes of the particles of solvent and solute.

By a similar, though less direct, method it has also been possible to show that the extra depression of the freezing point of salt solutions is determined by the increase in cohesion of the liquid that is due to the presence of the salt particles in it.

Further, it is possible to give a direct disproof of the dissociation theory. Edser's formula for the cohesion, K, of a pure liquid,

$$K = \frac{4S}{\delta}, \qquad . \quad . \quad . \quad (3)$$

can be extended to give the cohesion, K_2, of the dissolved particles in a solution, in the form

$$K_2 = \frac{4(S_{12}^{1/2} - S_1^{1/2})^2}{\ldots} \qquad (4)$$

As the values of K_2 given by this formula are involved in the vapour pressure formula (2), which has been found to be correct, there is no doubt that the formula (4) corresponds to the actual attractions between the salt particles in solution. From this formula the attraction between two particles of, for example,

potassium nitrate in solution, at a distance of, say, 10^{-7} cm., is found to be $6{\cdot}24 \times 10^{-11}$ dynes. If the particles were 'dissociated', the electrical attraction between the 'ions' at the same distance would be $2{\cdot}21 \times 10^{-5}$ dynes, which is of the order of a million times as great, and is impossible. Therefore, the potassium nitrate cannot be dissociated.

By taking into account the attractions between the particles, it is possible to account for the solubilities of different substances and to explain the mechanism of solution, which the dissociation theory was unable to do.

The results are evidence that the so-called failure of the classical dynamics is due, not to inherent defects in the method, but to the omission on the part of mathematicians to allow for the attractions of moving particles in close proximity to one another.

The Nucleus of *Amoeba proteus* Pallas (Leidy) [= *Chaos diffluens* (Schaeffer)].

IN "Ergebnisse mit der Nuclealfärbung bei einigen Rhizopoden", Aug. 12, 1929,[1] Bogdanowicz describes the effect of Feulgen's nucleal reaction on the nucleus of *A. proteus*. In a letter to NATURE (June 22, 1929) I briefly summarised my results of a long series of experiments on the same subject. It will be seen from a perusal of the two publications that our findings agree with regard to the presence of a reticulum of chromatin in the karyosome (a conclusion I had already arrived at by a study of the development of the nucleus[2]), but differ with respect to the nature of the so-called 'chromatin blocks' in the periphery of the nucleus. Bogdanowicz fails to obtain a chromatin reaction for these blocks. Now these 'chromatin blocks' have a twofold theoretical significance: (1) they form the karyosomes of the Agametes, (2) they show a very primitive type of mitosis.[3] It is, therefore, important to arrive at a decision with regard to their exact character. There is, however, another reason for endeavouring to clear up any discrepancies in the various descriptions of the nucleus of *Amoeba proteus*. As I have already pointed out, two large free-living amoebae have been confused under the name of *Amoeba proteus*, namely, *Amoeba dubia* (Schaeffer) and *Amoeba proteus* [Pallas (Leidy) = *Chaos diffluens* Schaeffer]. Therefore in making any reference to papers published before 1916 care should be taken to ascertain to which of the two amoebae reference is being made. As I know from experience, it is not always easy to do this. But failure in this respect is a fruitful source of confusion. Hence the justification of this summary of the results of many years' study of the nucleus of *A. proteus*, in its development and in its adult condition, by the ordinary microscopical stains; these results being checked and confirmed by a later investigation by Feulgen's method.

The nucleus of *A. proteus* consists of (1) a more or less centrally placed karyosome, (2) a peripheral achromatic network in which are suspended 'chromatin blocks', the whole immersed in nuclear sap and surrounded by a nuclear membrane. The karyosome is in the form of a thick disc with rounded edge, so as to appear circular in plan, 'band' shaped in elevation. It presents a variety of appearances when being rolled about in the cytoplasm, and thus changing from its 'plan' to its 'elevation' position.

The karyosome is made up of an achromatic ground substance on which is to be seen a reticulum of chromatin. The consistency of the karyosome differs in different specimens and varies according to the age of the amoeba and other circumstances. The amount and the distribution of the chromatin in the karyosome varies at different times. In the young, that is, immature, amoebae the karyosome is well marked off and is a conspicuous structure in the nucleus. But the chromatin is very sparse. In fact, I failed to get any positive reaction for chromatin in uncut nuclei, except the merest trace, until I had examined hundreds of specimens.

In the older, that is, fully differentiated, and adult amoebae the karyosome sometimes stains deeply by Feulgen's method, showing well-marked blocks and patches of chromatin which differ in colour tone in no way from the fully developed chromosomes in dividing nuclei of other animals and plants used by way of controls. At other times the karyosome appears to contain less chromatin.

It is important to emphasise the fact that chromatin is a living substance. It is, therefore, ever-changing, growing, increasing in amount, differentiating out of the chemical substances which build it up, dividing. The changes described above are clearly brought out when large numbers of *A. proteus* are studied by Feulgen's reaction, as is also the case when large numbers of amoebae are treated with aceto-carmine, as I pointed out long ago.

In the adult amoebae clearly defined chromatin blocks are to be found in the periphery, giving the reaction for chromatin by Feulgen's method as already stated. These similarly grow, differentiate, divide; when a 'block' is ready to divide, it stains very brightly; when it is in the 'resting' condition, it is not so evident and it does not stand out so prominently from the underlying ground substance.

In conclusion, I may add that, through the kindness of Prof. Robert Chambers of New York, I have been able to examine the *Amoeba dubia* of the States (it differs in no wise from the material obtained locally), and so to assure myself that not only do the cytoplasmic characters of the two species differ, but also, there is no karyosome in the nucleus of *A. dubia*.

Molecular Rotation in the Solid State.

THE determined crystal structures of a number of primary alkyl ammonium halides indicate that in such compounds the carbon atoms are arranged collinearly [1] in a particular group. Thus in the case of primary amyl ammonium chloride[2] the X-ray diffraction data from powders and single crystals can be completely explained by a tetragonal unit of structure containing $2NH_3C_5H_{11}Cl$ with $a = b = 5{\cdot}01$ A., $c = 16{\cdot}69$ A. The space group is D_4^2, V_d^3, S_4^1, C_{4v}^1, C_4^1, D_{4h}^7, and the Cl, N and C atoms are at $o\tfrac{1}{2}u$, $\tfrac{1}{2}o\bar{u}$, with $u_{Cl} = $ c. 0·095. The absence of reflections in odd orders from planes $(hk0)$ with $(h+k)$ odd and the intensities of reflections from other planes such as (200) require the carbon atoms of the C_5H_{11} groups to scatter X-radiation as if they are arranged collinearly in each group.

Prof. Linus Pauling, of the California Institute of Technology, has recently suggested to me that the indicated collinear arrangement of carbon atoms might be in error. If the carbon atoms of an alkyl group really have a 'zig-zag' arrangement and the group is

rotating[3] about its chain axis independent in phase of other rotating groups, then the result given above would be obtained. If the temperature should be sufficiently lowered, this complete rotation would be replaced by slight oscillation about some equilibrium positions.

Observations were made on primary amyl ammonium chloride at approximately liquid air temperatures. The density, determined by suspension in mixtures of liquid nitrogen and oxygen, is *c.* 1·0, probably a little greater than the value 0·953 at 25° C. Diffraction lines on powder photographs (CuK radiation) at liquid air temperatures are similar in spacings to, but markedly different in intensities from, those at room temperatures; some few additional lines requiring a larger unit of structure are also present. It is difficult to determine accurately the structural characteristics of such a complex compound from powder photographs alone. The photographs at liquid air temperatures, however, indicate, from their similarity to photographs at 25°, that the crystals have approximately orthogonal axes and that the atomic arrangement in the unit of structure containing $4NH_3C_5H_{11}Cl$, with the dimensions $a - b = 7·0$ A., $c - c.$ 16·6 A., is closely similar to that in the unit of structure previously described. The presence of planes such as (210) and (300), referred to the axes of the larger unit of structure, could be explained by alteration in the structure but probably is best accounted for by absence of the suspected molecular rotation that leads to the fortuitous determination of the unit of structure and atomic arrangement at room temperatures.

The best test for a possible collinear arrangement of the carbon atoms of a C_5H_{11} group is the absence of reflections in odd orders from planes ($hk0$) with ($h + k$) odd. (Indices referred to a unit of structure having $a = b = 5·0$ A., $c = 16·6$ A.). The large axial ratio makes it difficult to distinguish between reflections from ($hk0$) and (hkl) with l unity on powder photographs. Reflections from (200) and (201), however, are very weak at liquid air temperatures, while reflections from (200) are strong at room temperature. This change in the intensity of (200) could be explained by a great departure of the chain axes of the C_5H_{11} groups from parallelism with the tetragonal axis of the crystal at liquid air temperatures, or, as is most probable, by a departure of the carbon atoms from a collinear arrangement.

The most immediate conclusion is that the carbon atoms in a C_5H_{11} group are arranged in a 'zig-zag' manner and that the characteristics of the X-ray diffraction photographs made at room temperatures from crystals of primary amyl ammonium chloride arise partially from rotation of the C_5H_{11} groups about their chain axes. The configuration of a hydrocarbon chain as deduced from the crystal structure of the primary alkyl ammonium halides is thus probably the same as that first found by Müller and Shearer[4] for some long chain aliphatic compounds. The carbon to carbon separation along the chain axis is *c.* 1·20-1·30 A., and the carbon-carbon distance might well be *c.* 1·54 A.

It thus seems, as Pauling has indicated, that in a crystal containing molecules or molecular groups with small moments of inertia about some axes, these molecules may undergo rotational motion about these axes.

Raman Effect, Fluorescence and Colour of Diamonds.

THE Raman spectra of various simple substances, including especially the non-metallic elements such as phosphorus, chlorine, and carbon, have been investigated by me. In the course of this work numerous samples of diamond were examined, and a brief report of the results may be of interest as supplementing the accounts which have already appeared in NATURE of May 10.

The extreme sharpness of the Raman lines observed with diamond invited attempts to measure their wavelength with all possible precision. Seven different diamonds gave results identical within the limits of error of measurement. The best representative value for the infra-red wave-number was found to be 1331·5 ± 0·5 cm.$^{-1}$, in agreement with Ramaswamy's measurements but differing rather seriously from the value 1342 given by Robertson and Fox. In the case of

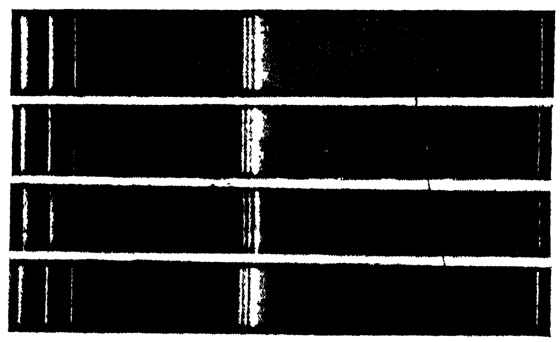

FIG. 1.

one very imperfect diamond, it was noticed that the line was diffuse and distorted and was accompanied by a faint companion line on the longer wave-length side.

A feature of importance not mentioned in NATURE of May 10 is the continuous spectrum accompanying the Raman lines. This appears with a fairly well defined edge on the violet side at about λ4240 A., and stretches out towards the visible region. Immediately preceding it are two bands of which the first at 4152 to 4162 A. is the more intense. The intensity of the bands and of the continuous spectrum varies in a remarkable way with the colour of the diamond. They are specially conspicuous with diamonds of a pale blue colour, and are extremely feeble with white diamonds. *Per contra*, the Raman lines are very difficult to observe with blue diamonds, and are most easily obtained with colourless diamonds.

In Fig. 1, *A* taken with a blue diamond and *B* with a white diamond exhibit these features. *C* was taken with a diamond having the palest yellow tinge and showed both the Raman lines and the bands accompanied by a continuous spectrum of considerable intensity. From the fact that the introduction of a filter cutting out the mercury line at 4046 A. eliminates the bands and practically the whole of the continuous spectrum, it may be inferred that these represent fluorescence of a special type. The aggregate intensity of the continuous spectrum appearing in *A* must have been very considerable, and it was thought that the blue colour of the diamond in ordinary daylight was really due to this fluorescent radiation. *D* was obtained with another diamond of a strikingly yellow colour. It gave feeble Raman lines, and a continuous spectrum (without bands) stretching practically over the whole region from 3800 A. to the red end.

210 Bowbazar Street,
Calcutta, India, June 14.

Raman Effect in Paramagnetic Crystals.

VARIOUS crystalline sulphates have been examined for their Raman spectra by the same method as that used for crystalline nitrates and described previously (NATURE, Mar. 22, p. 463). The results indicate what appears to be a very remarkable influence of the paramagnetism of the cation on the intensities of the Raman lines. This appears very clearly when we compare the spectra of ferrous sulphate crystals ($FeSO_4$, $7H_2O$) with those of other isomorphous sulphates, for example, magnesium or zinc. In the latter substances, a strong line appears with a frequency shift of about 980 cm.$^{-1}$. This frequency is characteristic of the SO_4^{--} ion, though its exact value shows considerable variations with the cation present in the crystal. In the spectrum of the ferrous sulphate crystals, however, the line fails to appear even when exposures are given of such duration that the feeble continuous spectrum accompanying the mercury lines comes out strongly on the plate. With aqueous solutions of ferrous sulphate, however, the SO_4^{--} line appears feebly.

That the disappearance of the SO_4^{--} line with ferrous sulphate crystals is connected with the paramagnetism of the substance is indicated by the fact that in other paramagnetic sulphates, as, for example, those of copper and manganese, the characteristic SO_4^{--} line appears only weakly. A similar weakening of the line due to NO_3^- inactive frequency is also noticeable on comparing the nitrates of copper and manganese with the nitrates of other metals. The observations indicate that when the substance is in solution, the influence of the paramagnetism of the cation weakens or disappears.

Submarine Cable Interference.

THE description given by E. T. Burton [1] of his measurements of audio frequency interference is of great interest, and would be more so if quantitative values of the interference levels had been given. The similarity between the natural interference experienced on an untuned aerial and a cable is to be expected, but details of the depth and armouring of the cable would be valuable to estimate approximately the attenuation of the higher frequencies. Mr. Burton does not state whether a local earth was used, or a sea earth contiguous to the main cable; nor the length of the latter, if used.

An attempt at correlating the 'intermediate frequency' interference with the strength of the aurora borealis might meet with success; this suggestion is supported by (*a*) the partial correlation with magnetic disturbance, (*b*) the higher level at night, and (*c*) the interference level being on the increase when observations were apparently discontinued in September 1929. Extremely heavy and rapidly varying earth currents were observed at the Horta end of the Bay Roberts-Horta (1928) cable during the evening of Sept. 8, 1928, simultaneously with exceptional aurora at Bay Roberts.

The practical importance of interference measurements on submarine cables lies in the limit set by the interference level to the smallness of the received signals, and hence to the permissible amplification, both at low frequencies for telegraphy and at audio frequencies for telephony. The recent suggestions for a loaded trans-Atlantic telephone cable [2] will depend for their success on the degree to which natural and artificial interference can be eliminated, as for example by long, resistance-terminated sea earths, or by screening the cable by a high-permeability alloy. This will be realised when it is stated that an overall amplification of the order of 150 decibels will be required at about 2200 to 2500 c.p.s.[3]

The programme of tests on the La Panne-Lisbon cable, to be laid by the Telegraph Construction and Maintenance Co., Ltd., for the Italcable Co. later this year, includes the recording of telegraph frequency interference (from 0 to 200 c.p.s.) at La Panne. Should sufficient time be available, I hope to extend these observations to cover the audio frequency range. At this location, with a long length of cable in shallow water down the Channel, it is anticipated that the industrial interference will be very heavy; but the character and intensity of natural interference may be similar to that obtained at Trinity Bay.

The Green Ray.

THE extract from a letter to NATURE by R. W. Wood (vol. 121, 1928, p. 501), in Sir Napier Shaw's recently published "Manual of Meteorology", vol. 3, suggested to me that an observation of the green ray I obtained last spring might be worth recording.

Wood remarks that the ray is more likely to appear when the horizon at which the sun sets is markedly colder than the air close above it.

While descending in clear weather as a passenger in a motor-car into a valley in Kincardineshire I watched the artificial sunset due to the obscuring of the sun by a hill some three miles away, the country being several inches deep in snow; the sunset occupied about five seconds; the last-disappearing edge of the sun turned from orange through yellow to a grass green. In spite of the rapid sunset which should have been unfavourable for seeing any green ray, the sharp increase of temperature with height usual above a snow surface appears to have produced a sufficiently high dispersion.

Plasmoidal Discharges in Gases.

IN the issue of the *Physical Review* of April 1, 1930, there appears a paper by Prof. R. W. Wood on high frequency discharges in gases at low pressure in which he describes a type of discharge, naming it a plasmoid. This appears to be a new name for a phenomenon which has been described before. In particular, it appears to be the same as a type of discharge described briefly by me in NATURE of Mar. 10, 1928. Such a discharge was also shown by Messrs. Gill and Donaldson at an exhibition during the British Association meeting at Oxford in the summer of 1926.

It does not appear that Prof. Wood has verified his references carefully. I find that a paper which was published by him in the *Philosophical Magazine* in August 1929 is referred to in his recent paper as having appeared in October 1929.

Also in his paper in the *Philosophical Magazine* of August 1929, he refers to another paper published by him in NATURE of Oct. 8, 1927, as having been published in NATURE 1926.

S. P. MCCALLUM.

Electrical Laboratory,
Oxford, June 6.

The Royal Society of Canada.

ANNUAL MEETING IN MONTREAL.

ON May 20-22 the Royal Society of Canada met at McGill University, Montreal. Prof. A. S. Eve gave his presidential address on the evening of May 20, his subject being "The Universe as a Whole". He dealt successively, and from the broadest point of view, with the macrocosm, space, the microcosm, atoms and electrons, the age of the universe, time, life and the origin of life, and domains of energy, and stressed the divergence of existing views on may important problems, and the number of such problems still to be solved. At the same session he presented the three gold medals of the Society. The Flavelle medal was awarded to Dr. A. B. Macallum, emeritus professor of biochemistry at McGill University, for his pioneer researches in micro-biochemistry, the Lorne Pierce medal for outstanding contributions to literature to Sir Andrew McPhail, professor of the history of medicine at McGill University, and the Tyrrell medal to Dr. Adam Shortt, of Ottawa. At the final session of the meeting the Hon. Vincent Massey, Canadian Minister to the United States, gave the popular lecture on "Art and Nationality in Canada".

Perhaps the most interesting and outstanding event of the whole meeting was the radio address delivered by Sir Ernest Rutherford, president of the parent of all Royal Societies, from his home in rural England to the fellows gathered in Moyse Hall at Montreal. The whole of the address, with the exception of a few opening sentences, was clearly heard by a large audience, as was the telephone conversation between Sir Ernest, at one end, and in turn Prof. Eve, Sir Arthur Currie, and Sir Robert Falconer, at the other. Only ten years previously it had been considered a remarkable event when, also under the direction of Prof. Eve, an artiste sang at Montreal to an audience of the Royal Society at Ottawa, 110 miles away (and the reception was much less perfect).

In Section I. (French Literature and History) eleven papers were read, and in Section II. (English Literature and History) twenty-five.

Section III. had to divide into sub-sections to hear the ninety-nine papers presented. The sectional presidential address was delivered by Dr. Daniel Buchanan, of the University of British Columbia, who spoke on the three-body problem and gave the historical development of this famous mathematical investigation. Prof. J. C. McLennan communicated a large number of papers by himself and his colleagues on spectroscopy and low temperature work. One paper with H. D. Smith and G. O. Wilhelm reported results indicating that there is no appreciable difference in the states of oxygen molecules in gas and in liquid form. Prof. McLennan himself described the construction of a new type of spectrograph which will photograph the auroral green line in less than twenty minutes, permitting comparison of its intensity in the light from the night sky for different periods of the night. With E. K. Moles he has found that there is appreciable absorption of the green auroral line in oxygen at high pressures. An interesting paper (with J. F. Allen and J. O. Wilhelm) on the non-superconductivity of bismuth alloys was also presented.

Dr. J. A. Gray gave several papers on X-rays and radioactivity. The most interesting of these (in conjunction with W. H. Zinn) showed that the scattering of X-rays at small angles to within five minutes of arc of the primary beam indicated an abnormal scattering with certain specimens of charcoal; the intensity increases so rapidly as the angle decreases that it is difficult to measure relative intensities accurately. Figures obtained show that with a certain specimen of charcoal the intensity of the scattered radiation at five minutes of arc is of the order of a million times that at ninety degrees. This abnormal scattering is also shown by the fact that the part of the mass scattering coefficient for radiation scattered between ten and ninety minutes is equal to 6·0, which may be compared with the total normal scattering coefficient which is of the order of 0·2. The scattering increased with rise of temperature. Different wave-lengths were used and it was not found possible to give an explanation of this new phenomenon in terms of the wave theory.

Dr. J. K. Robertson in a mathematical paper gave a rigorous treatment for measuring the half-width of spectral sources. Dr. A. N. Shaw and H. E. Reilley described a new method enabling the comparison of electrical voltages measured at different times and places to be made with the exceptional precision of two parts in a million. Dr. J. S. Foster and his students presented several papers relating to the Stark effect, including one (with H. W. Harkness) in which it was shown that in xenon the usual rule for hydrogen differences is not applicable. Papers on applied geophysics were presented by Prof. A. S. Eve, Dr. L. Gilchrist, and Dr. D. A. Keys, in which accounts of field work by different electrical and magnetic methods were described. An interesting demonstration of the piezoelectric pressure gauge combined with a cathode ray oscillograph was shown by H. G. I. Watson and Dr. D. A. Keys. Dr. W. L. G. Williams gave a paper on applications of the theory of formal molecular invariants to the theory of numbers, which leads to some rather general arithmetical results. Dr. S. Beatty spoke on the rôle of equivalent lines in a bilinear transformation in the plane, and Dr. C. T. Sullivan gave an interesting account of an investigation on an application of matrix rank to the classification of surfaces defined by a certain system of differential equations.

In the Chemical Sub-section Dr. Otto Maass and R. H. Wright described the physical properties of the system hydrogen sulphide–water, and F. R. Moorehouse and Dr. Maass described the preparation and properties of ethyl acetylene. Dr. R. H. Clark and E. G. Hallonquist reported a study of the

effect of a magnetic and also of an electrostatic field upon the ethylene linkage of the two electromers of 2-pentene. Dr. F. B. Allan gave a paper on the reaction of the solvent alcohol on dissolved esters in presence of calcium alcoholate, ammonia, or sulphuric acid. R. E. Whiting and Dr. W. H. Martin showed that extreme drying had no effect on either the light absorption or the photo-expansion of bromine. Dr. E. H. Archibald and F. Rendle made a communication on the solubility of beryllium hydroxide in solutions of sodium bicarbonate and the separation of beryllium from vanadium, chromium, and uranium.

In Section IV. (Geological and Mineralogical Sciences) thirteen papers were given, Mr. A. G. Burrows, provincial mineralogist for Ontario, presiding. Dr. F. S. Alcock presented a paper on the Silurian of Northern New Brunswick; his recent work in the Chaleur Bay region has indicated that Ordovician and Devonian as well as Silurian strata occur in the north-western part of the province, formerly mapped as occupied by Silurian; he included a discussion of the relations of the Silurian with older and younger strata. Dr. M. Y. Williams, in a paper on the Pierre Seas of Western Canada, advanced evidence to show that the great Colorado sea retreated to the north and south, leaving western Canada dry land. The rhythm of earth movements, however, continued, although with decreasing amplitude, and two or more invasions of the Pierre Sea closed the marine history of Cretaceous time. He discussed the areal extent, duration, and significance of the Pierre submergence.

W. A. Johnston and R. T. D. Wickenden gave a paper on the hitherto undescribed Glacial Lake Regina, Saskatchewan, which extended for 175 miles south-east from the elbow of the South Saskatchewan River, and had a maximum width of about 40 miles. The lake was formed as a result of damming of the drainage of the South Saskatchewan River by the retreating ice sheet of the last glacial epoch and outflowed towards the south-east by way of the Souris valley. In two other papers W. A. Johnston brought together scattered data regarding the occurrence of permanently frozen ground in northern Canada, discussed the question of the relationship of the frozen ground to present and past climatic conditions in the glaciated and unglaciated parts of Canada, and offered evidence in support of J. B. Tyrrell's view that fossiliferous clays on Roaring River, Duck Mountain, Manitoba, are interglacial in age. Dr. G. S. Hume dealt with features of foothill structures in Alberta, and pointed out that recent drilling for oil and gas in these foothills west of Calgary has revealed the presence of overthrust blocks lying on one another and separated by low-angle thrust planes dipping south-westerly. Turner Valley, New Black Diamond, and Jumping Pound structures are recumbent folds modified by faulting. Late Cretaceous rocks are believed to underlie and to be separated by a thrust fault from the Palæozoic rocks productive of oil and gas in Turner Valley, and it is suspected that the whole disturbed belt in this area is overthrust on to the relatively flat-lying sediments of the plains.

In Section V. (Biological and Medical Sciences) fifty-nine papers were presented, and in addition Dr. Szent-Gyorgyi, a guest at the meeting, gave a demonstration of the properties of hexuronic acid. Dr. A. T. Cameron, of the University of Manitoba, gave the presidential address of the section on temperature and life and death. Dr. Wm. Rowan communicated a description of a new species of *Hydra* found covering water-weeds in certain Albertan lakes; the body and tentacles when extended may measure four inches. Eggs are deposited in autumn and survive the winter. According to Dr. A. Willey, the young garpike, when less than a foot long, possesses a double tail, each part working separately; the tail-fin is a soft muscular process, which vibrates with great rapidity. Dr. C. M. Fraser reported the results of a study of the razor clam of the Queen Charlotte Islands. Dr. J. Playfair McMurrich presented a series of papers from the Anatomical Department of the University of Toronto. Amongst these was a report by Dr. J. C. Watt of a case of an adult man in whom there was a complete union of the membranes surrounding the heart and left lung, whence it was concluded that a special membrane of the heart is not necessary for its efficiency. Dr. H. A. Cates showed that the relative proportions of length and width of the skull do not alter to any considerable extent between infancy and adult life, but that the relative height, with measurement taken from the Frankfort plane, increases greatly. Dr. R. K. George showed, as determined by methods of precision, that in the majority of men the ring finger is longer than the index; in women the opposite holds. Dr. C. C. Macklin, of Western University, presented a study of stereoscopic X-ray films of lipiodolised lungs, which demonstrated that in inspiration the bronchial tubes become shorter and narrower, and in expiration the process is reversed, these changes facilitating air exchange, and being correlated with the minute anatomical structure. A network of smooth muscle with abundant elastic tissue envelops the tubes and controls the action. The results have a direct bearing on pathological conditions of the lungs such as pneumonia and tuberculosis.

Drs. J. G. Fitzgerald and D. T. Fraser, of the Connaught Laboratories, Toronto, presented an extended series of observations indicating that infants non-immune to diphtheria are the offspring of mothers who possess no natural protection, while the blood of adults shown to contain antitoxin continues to contain it for a period of years; non-immune adults remain non-immune. H. des B. Sims and D. A. Scott reported two absorption bands in the ultra-violet spectrum of solutions of crystalline insulin. Exposure to ultra-violet radiation lessens the potency of insulin. X-ray radiation produces no effect. A. F. Charles and D. A. Scott, from a study of enzymic digestion of crystalline insulin, find that loss of physiological activity apparently proceeds even faster than digestion, the result indicating that the activity is associated with the large molecule itself and not with some

constituent part of it. Dr. J. B. Collip, of McGill University, and his co-workers, outlined the preparation of the placental hormone emménin, and showed that immature female rats are brought to sex maturity by its injection, thereafter manifesting cyclic changes, while normal adult females are unaffected. R. L. Lutz outlined a method for determining potassium, sodium, calcium, and magnesium in biological material after initial fusion with fuming nitric acid, and described a crystalline organic substance isolated from fuming nitric acid hydrolysates of the protein fraction of beef muscle and of casein.

Drs. V. J. Harding and L. J. Harris, of the University of Toronto, described the production of convulsions and subsequent death in dogs after forced ingestion of large quantities of water. Recovery from the convulsive stage is rapid following intravenous or intraperitoneal injection of ten per cent saline. Dr. John Tait and W. J. McNally, of McGill University, reported that the croaking of frogs is essentially an under-water signal, conveyed by vibration, this vibration occurring when air is shifted from the lungs to the mouth and air-sacs. The fact that croaking can be heard merely implies that the signalling animal has its head above water at the moment. Dr. B. P. Babkin gave an account of a number of studies of gastric and intestinal digestion by himself and his students. Prof. A. H. R. Buller reported on some further experiments on sex in fungi. Dr. Marie-Victorin gave an account of a study of the literature and of the plant *Elodea canadensis*, leading to greater precision of nomenclature, and Prof. G. W. Scarth presented a series of sinkage studies of floating logs of various trees, the relative amount and distribution of the three phases, wood, water, and gas being studied by gravimetric and microscopic methods. Prof. F. E. Lloyd presented a comparative study of the traps of *Utricularia gibba*, *vulgaris*, and *capensis*.

The Society, under the presidency of Dr. Charles Camsell, Deputy Minister of Mines of the Dominion, has accepted an invitation from the University of Toronto to meet there in 1931, whilst a similar invitation to meet in Vancouver in 1932 was referred to the Council for favourable consideration.

A Study of the Phenomenon of Spin in Airplanes.*

By H. E. WIMPERIS, C.B.E.

METHOD OF STUDY.

SO much for what the spin is and what causes it. We come now to the best way to study it. This can be done by employing models or by the use of full-sized airplanes. The latter method avoids uncertainties due to any possible 'scale effect', that is, failure of the model to represent truly the motions of the full-sized machine, but adds the greater difficulty of making accurate quantitative measurements when in free flight and adds the risk of crash. Experiments with models have been made in wind tunnels and in free flight. Small light models—to one-twelfth or one-twentieth scale—have been made at Farnborough out of balsa wood, and these have been dropped through a free fall of 90 feet in the large balloon shed. Kinematograph records have been made and the motion afterwards measured up from the films. (One of these films was shown on the screen.) In certain of these model dropping experiments a Bristol Fighter model was used, and success attended the effort to reproduce various types of spin. In this particular machine the rudder was found to be surprisingly effective as a controlling organ, and if the spin were started against this control it was stopped in six turns.

Of all the various controls the aileron is normally the least effective; that is, the ordinary type of aileron. If, however, the possible aileron angle is arranged to be *very* largely increased, the spinning motion is affected. The following account of a model dropping experiment at Farnborough will serve alike to indicate this aileron effect and to illustrate the nature of this mode of this form of experimentation. A 1/20th scale model of a Bristol Fighter was used. Ailerons were fitted to the upper and lower starboard wings and provision was made for moving any of the controls at a predetermined time during the spin. This was done by means of a spring loaded dash pot with a variable air leak. The model was released from a swinging pendulum just under the roof of the balloon shed in such a way that it was at release moving horizontally at its stalling speed with 10° of sideslip. It was launched with full left rudder and with the elevators fully up. With ailerons neutral the model completed 4½ turns of a left-hand spin in as many seconds. A further test was then made with control release set to move the outer aileron to an angle of 65° after an interval of 2½ seconds, with the result that the model ceased spinning within about half a turn.

The flat spin with this model was found to be one of very small radius, the mean angle of incidence appearing to be about 75° (the smallness of the radius in flat spins is of course well known, as is the consequent extraordinary difference sometimes found in the centrifugal forces acting on the pilot's and observer's bodies). Whereas in the ordinary spins of this model four and a half turns were made in four and a half seconds, in the flat spin, eleven turns were completed in five and a half seconds, and the axis of the spin instead of being well ahead of the nose came close to the centre of gravity.

Sometimes the little model was made automatically to centralise its controls during the fall, and the effect of this on the resulting motion was studied. Sometimes the models were set into a spin at the moment of release and the effect of variations in wing arrangement ascertained. In this way the effects of stagger, wing gap, decalage, and other features can be studied rapidly This

* Continued from p. 136.

has proved a useful method of investigation; it is safe, speedy, and very picturesque.

The other way of using models is to mount them in a wing tunnel and measure the forces which arise during the spinning motion. This is an exceedingly difficult experiment to carry out for the motion is complex, and it is no very easy matter to lead out the connexions which will enable the couples about each of the axes to be measured. It is not so difficult to measure the moment about the autorotation axis, the axis of spin, and this investigation is now in hand. The amount of the autorotation moment will of course give a measure of one at any rate of the forces tending to keep the airplane in the spin. The fuller experiment will, however, be undertaken in one of the N.P.L. wind tunnels as soon as the apparatus is ready.

Yet another form of wind tunnel test is due to Prof. Betz. This consists in measuring the rate of autorotation of a hollow aerofoil in which air can be allowed to pass internally from one wing tip slit to the other. These slits are placed in the upper surfaces and are parallel to the wing spar. Measurements have been made in Germany with these slits in different symmetrical positions and with or without a free internal air passage. The result is found that with the best arrangement there is at some cost of maximum lift a distinct decrease of the tendency to autorotation, and that this gain is directly associated with the free lateral passage of the air inside the wing. The following explanation of the action is given by Schrenk.[1] It is known that the motion of a rotating wing produces different angles of incidence at corresponding sections of the two ends, such that at the rising end the flow adheres to the upper surface whilst at the other end it tends to break away. For this reason the lift on two such corresponding elements is not necessarily the same, and in no case will the pressure distributions on the elements coincide. The flow from slit to slit through the wing is caused by such differences of pressure, and acts in such a way that at the wing tip at which the flow breaks away from the surface the flow is improved by suction of the boundary layer towards the interior of the wing; at the other end the flow is rendered worse by the air streaming out of the slit. It follows that any autorotation there may be will tend to be much slower and therefore more controllable.

The first full scale experimental and mathematical investigation of spinning was that by Lindemann, Glauert, and Harris. This work was carried out at Farnborough, and in their report to the Aeronautical Research Committee, dated March 1918, full details of this very courageous investigation are given. It is noteworthy that they made use of streamers attached to outrigged spars, and by their use measured for the first time the angle of incidence.

At the present time full scale research on spinning is included in the research programme at Farnborough. Indeed, the phenomenon is one which requires continuous study since each new development of airplane design may bring in some new aspect of the spinning problem.

In addition to this work there are the normal 'performance tests' on spinning which are carried out at Martlesham on all new types of airplane, during which each machine is spun through not less than eight turns to right and to left with varying positions of the centre of gravity, and no machine is passed for service unless it can be readily bought out of such a spin by the normal use of the controls. Intrepid pilots are needed for such tests on new machines, and it does sometimes happen that the obstinacy of the airplane in its motion requires the pilot to resort to his parachute, though, curiously enough, the mere rising of the pilot in his seat with the view of leaving the airplane has on more than one occasion caused the machine to come out of its spin at once! Sometimes the engine throttle can be used as a control on the spin, since change of engine torque will of course tend to roll the machine to a new attitude. Spinning tests have also been undertaken by the Cambridge University Air Squadron with the help of Prof. Melvill Jones. In these tests the wool tuft method due to Flight Lieutenant Haslam has been found of use. This consists of mounting numerous little tufts of wool on the upper surface of the wing and watching (in some cases taking cinema records of) what happens when the machine gets into various attitudes. As I have already mentioned, a rather similar method of experiment has been used at Farnborough, in which long streamers have been attached to the wing tips or other airplane parts and their motion studied in the spin.

It is not pretended that the behaviour of these streamers is understood, but it is hoped that the continuation of the research will bring such knowledge as will enable these results to be usefully interpreted. As an example of the complexity the following extract may be given from a Farnborough report:

> It was decided to investigate the practicability of recording the direction of the air flow over various parts of the airplane while spinning by photographing streamers. Outriggers were fixed to the lower planes. These were attached to the front spars and projected two feet beyond the wing tips, fabric streamers four feet in length being attached to the ends. Streamers were also fixed to tubes projecting 9 inches in front of the leading edge of the tail plane three feet from the plane of symmetry. . . . The inclination of the wing tip streamers was found to vary in phase with the oscillation of the spin. In the left hand spin the mean inclination of the inner streamer to the wing cord was 73° and that of the outer streamer 24°. . . . The photographs of the tail plane streamers were less satisfactory, and it was only possible to determine the inclinations of the inner streamer; . . . the mean inclination of the streamer was about 15° from the *Z* axis towards the rudder, which implies a natural flow at the streamer which is opposite in direction to that caused by the rotation of the tail. An inward sideslip of the order of 20° would satisfy these conditions.

These experiments show that in nearly flat spins where the rate of rotation is high and the vertical velocity small, the tail unit has to operate in air previously disturbed by the passage of the wing tips. This disturbance of course does not add to the effectiveness of the tail control organs. The

sole merit to be found in the motion in a flat spin is that the vertical velocity is quite often so small that little more than a crashed under-carriage results from hitting the ground. In this type of spin the wings are acting rather like those of an autogiro, but very inefficiently, of course, since one wing is entering the air by its trailing edge.

Another method of full scale test making use of a kinematograph camera on the ground has been employed in Germany. The size of the image on the film gives a rough measure of the distance away of the airplane, whilst the angular distance and the time are readily noted. Cinema methods are also in use in U.S.A. (A cinema film furnished by the National Advisory Committee for Aeronautics of America, and showing a seaplane performing a flat spin, was shown at the end of the lecture.)

When new types of airplanes are tested at the R.A.F. Station at Martlesham in order to ascertain their performance under all conditions of flight, they need to be spun both to left and right and not merely in one direction only. This is because of the influence of the direction of engine rotation upon the slip stream, and because of the gyroscopic couple due to the rotating engine and airscrew which will try to depress the nose of the craft in one case and raise it in the other. Recovery is required to be simple and sure even when this gyrostatic couple assists the inertia couple in opposing the pilot's actions.

At first it was not realised that an airplane that could easily be brought out of a spin of a few turns would not necessarily be easily brought out if the spin were continued for a large number of turns. The reason for this is not certainly known, but it can scarcely fail to be associated with sheer lapse of time allowing the forces opposing recovery gradually to raise the nose of the machine, and so get it into a condition in which for one reason or another the pilot's controls are less effective. Nor has it long been realised that the effect of small differences in the actual mode of entry into the spin can persist even after many turns, and so sometimes render recovery unexpectedly difficult. This explains the previously puzzling question why pilot A's report on the controllability of a given machine in a spin differs entirely from pilot B's. The explanation no doubt is that the two pilots follow a slightly different technique in putting their airplanes into spins. For research investigations it is feasible always to employ the same technique, but during the performance testing of new aircraft consideration must be given also to what is likely to happen when this definite technique is not followed.

THE WOOF.

A recent discovery is the 'Woof'. This is a word coined by the Martlesham pilots to describe the unsteady form of spin sometimes met with in which there is an oscillation in pitch combined with an oscillation in spin, so leading to a very uncomfortable motion. This is so little understood at the moment that one of the Air Ministry Scientific Research Staff in a recent report had to admit that "the origin of the air forces necessary to maintain this fluctuation in attitude is at present a mystery, and this obscurity is typical of the present stage of the spinning problem". In one recent test the jerkiness of the motion could be distinctly seen from the ground. The unevenness of rotation was accompanied by an appreciable oscillation in pitch, the rate of rotation decreasing as the nose of the aircraft rose and increasing as it fell. Accelerometer records showed the mean period of the pitch oscillation to be rather more than 5 seconds, whereas the corresponding mean times per turn of these spins was only about 4½ seconds. The complexity of the motion may be inferred from the different periodic times.

It may be of course that, long before these highly complex phenomena are fully understood, some novel constructional device will be produced which will at once render all spins controllable. A device which went so far as to prevent spinning altogether would probably not be desirable since it might also prevent the useful manœuvre of the 'roll'.

It is true, I fear, that in these matters we ask a great deal. We ask that the airplane shall do everything that the pilot wishes, but shall have no will of its own other than a moderate wish to remain the right way up, but even this not to be thrust too prominently before the pilot's notice. We want a docile machine. We want, in fact, an amount of docility which though often sought is but rarely found, even in humanity.

[1] *Z.T.M.*, Nov. 14, 1929.

Obituary.

MR. W. J. GREENSTREET.

BY the death of William John Greenstreet on June 28 the mathematical world loses, not an explorer or a geographer, but, if the metaphor may be pressed, a traveller familiar with a larger variety of landscape than almost any of his contemporaries. Born in 1861 and educated at St. John's College, Cambridge, he was an assistant master from 1882 until 1889, and headmaster of Marling School, Stroud, from 1891 until 1910, when he retired to Burghfield Common, near Reading, with the intention of devoting himself to literary work. For many years he had been a regular contributor to *Notes and Queries* and to the *Westminster Gazette*, and editor of the *Mathematical Gazette*, and he had every reason to anticipate a life congenial to his frugal tastes.

The War, however, put an end to Greenstreet's work for the *Westminster Gazette*, and at the same time raised the cost of living to an unforeseen level. The result was an extension of an activity which he had created, namely, the supervision of the

education of pupil-teachers in village schools; the value of this work, which he had begun voluntarily in the schools nearest to his home, came to be recognised by the county educational authorities, and soon from eighty to ninety students looked to him for guidance, and he was known throughout the countryside, reaping in labours which earned him a livelihood the reward of spontaneous help given to his neighbours in happier years.

Meanwhile his editorship of the *Mathematical Gazette* continued, and it was this which made Greenstreet's name familiar to every mathematician in England. While the *Gazette*, as befits the organ of the Mathematical Association, has been concerned primarily with problems of school teaching, from elementary arithmetic to scholarship analysis, the characteristic features of the journal have revealed the editor. Greenstreet always desired to attain, and believed that all teachers benefit if they can attain, to such appreciation of current advances in mathematics as is possible without intensive study of special branches; he therefore encouraged ample notices of treatises, Continental and American as well as English, far beyond the range of school mathematics, until the review pages of his *Gazette* were admitted to be among the best in the world. Also, he had an immense knowledge of the personalities of literary, scientific, and social history, the product of omnivorous and rapid reading and a retentive memory; one result was that his own reviews of historical works, now tracing cross-currents of influence, now bringing a dead name to life by an anecdote or an epigram, enriched alike the books with which they dealt and the journal in which they appeared; another result was that every spare corner of the *Gazette* was filled by a 'gleaning', some quaint incidental reference to mathematics or to a mathematician found perhaps in classical literature, perhaps in a daily newspaper. In short, Greenstreet gave a character and a standing to a periodical which might have become nothing but a pedagogical mouthpiece; and this was the achievement that was acknowledged when the completion, in 1929, of thirty years of his editorship was the occasion of a testimonial to which some two hundred mathematicians subscribed.

Of Greenstreet's literary and musical interests it is impossible to speak here, but mention must be made of his enthusiasm for De Morgan. Once he was addressed as the De Morgan of his time, and this compliment pleased him as no other ever did. In wealth of biographical and bibliographical knowledge each was indeed unrivalled in his day, and this was perhaps all that the comparison was intended to convey, but one may recognise also in the two men the same sense of honour and the same sense of humour. Of the multitude of correspondents and contributors who were grateful for Greenstreet's help and counsel, few could claim to know him personally. His friends hold the memory of a man who never spoke a wounding or complaining word, of one who was prodigal of his knowledge, forbearing in his judgments, and ready with his laughter.

E. H. N.

Mr. G. H. Curtiss.

It is with great regret that we record the death at Buffalo, U.S.A., on July 23, after an operation for appendicitis, of Mr. Glenn Hammond Curtiss, whose name, as a pioneer of flight, will always be associated with those of his countrymen, Langley and the Wright brothers. Curtiss, who was born at Hammondsport, New York, was only fifty-two years of age and was therefore somewhat younger than either of the Wrights. Like them, he began life as a bicycle repairer and then turned his attention to motor cycles, motor racing, and engine making.

It was the chance order of an engine for an airship which stimulated Curtiss's interest in aviation. The Wrights had first flown in 1903, Santos Dumont in 1906, and experiments were being made by many other inventors. It was, however, the performances of Orville Wright at Fort Myer, U.S.A., and of Wilbur Wright at Le Mans, France, in 1908 which definitely established the aeroplane as a practical means of transport. That same year, flights were made by other pioneers, among whom was Curtiss. In the summer of 1908 he flew his machine, *June Bug*, a distance of a mile, and this success he followed up by competing with distinction at the famous Rheims meeting of 1909, while in 1910 he won a prize of 10,000 dollars for a flight from Albany to New York, two places associated with the historic voyage of Fulton's steamboat *Clermont* a hundred and three years before.

Continuing his work, Curtiss in 1911 produced the first hydroplane, and by 1914 he had taken up the serious construction of aircraft and had built a multi-engined flying boat. The vast extension of flying during 1914–18 led to the execution of many orders for Great Britain, Russia, and the United States, and to-day the firm Curtiss founded is one of the largest organisations of its kind in the United States.

Curtiss also came into prominence through the Hammondsport trials of the Langley flying machine, which had been tried, but without success, in 1903. Langley died in 1906 but his machine was preserved at the Smithsonian Institution, of which he had been the secretary. Placed in the hands of Curtiss in the spring of 1914, the machine was modified to a certain extent, and on May 28, 1914, Curtiss flew it a short distance. Other trials followed with a Curtiss engine fitted to the machine. These events, together with the wording of the label of the machine as it stood in the museum, unfortunately led to a bitter controversy. Curtiss himself at the time was defendant in a lawsuit concerning the Wright patents, and it is generally agreed that the machine should never have left the museum. The action of the authorities of the Smithsonian Institution has often been criticised, but a short time ago the present secretary, Dr. C. G. Abbot, published a pamphlet in which an effort was made to do justice to all concerned.

News and Views.

THE economic difficulties which beset agriculture has focused public attention on the industry, and to judge by the many remedies which have been put forward, it would not be surprising if the general public and even the farmer himself concluded that science as applied to agriculture has failed in its efforts to improve the lot of the agricultural producer. It is fitting, therefore, that a considerable proportion of the programme of Section M (Agriculture) for the Bristol meeting of the British Association will be devoted to the discussion of two subjects, namely "Veterinary Science and Agriculture" and "Management of Grass Land", the economic importance of which it is not easy to exaggerate. The former is the subject of the presidential address, to be delivered by Dr. P. J. du Toit, who has given a new lead to veterinary thought, and by his work on the relationship of nutrition to the incidence of disease has opened up a field which may enable the sorely pressed farmer to minimise the enormous losses caused to his herds and flocks through the ravages of disease. A full morning session is to be devoted to the address and the subsequent discussion, and amongst those who will take part are Dr. W. H. Andrews, Major Walter Elliot, M.P., Sir Robert Greig, and Dr. J. B. Orr. To the discussion on grass land management, Mr. Jenkins of Aberystwyth will present the plant-breeders' viewpoint; Dr. Orr and Mr. Godden, of the Rowett Research Institute, the nutritional aspect; and Prof. Hanley of Newcastle will deal with the matter from the animal side. In accordance with the usual practice in the Section, an afternoon session will be devoted to a series of short communications outlining the scope and character of the agricultural work undertaken by the University of Bristol. In addition there will be several technical papers and Sir John Russell will open a discussion on the "Influence of Fertilisers on the Yield of Crops".

THE programme of the Ninth International Horticultural Congress, which is to be held in London at the invitation of the Royal Horticultural Society on Aug. 7–15, has now been issued to members. The main subject for discussion at the Congress will be "Propagation, Vegetative and Seminal", and papers on this subject will be given in the Greycoat Hall on Friday, Monday, and Wednesday, Aug. 8, 11, and 13; on intervening days the members of the Congress are offered the choice of a very interesting series of excursions, including visits to various private gardens, to the Royal Horticultural Society's Gardens at Wisley, to the various research stations of interest to horticulturists, and to many of the big commercial nurseries, plantations, etc. Papers for the Conference are so numerous that the executive committee has arranged for three meetings to proceed simultaneously on each of the days given to papers. The papers have therefore been grouped so far as possible under three heads: (1) Propagation, (2) pomology, and (3) tropical and sub-tropical horticulture. Under each section communications are offered by British, American, and European workers, and many topics of considerable scientific interest are represented on the programme.

IT is only possible here to indicate some of the main items for discussion at the Ninth International Horticultural Congress. Vegetative propagation from the point of view of plant anatomy will be discussed by Dr. van der Lek (Holland) and Prof. J. H. Priestley, whilst practical and experimental methods will be discussed by Dr. R. J. W. Graham and Mr. L. B. Stewart from Edinburgh and Miss Mary E. Reid and Dr. Zimmerman (U.S.A.). Mr. Niels Esbjerg (Denmark) will describe some of his experiments in inducing scion varieties to grow upon their own roots. The forcing of dormant buds will be discussed by Dr. Denny and Prof. Loomis (U.S.A.), whilst British workers will discuss polyploidy in connexion with graft hybrids, sterility and vegetative mutations in potatoes. The directors of the East Malling and Long Ashton Research Stations are to speak in the Pomological Section, where also Russian, Polish, Czechoslovakian, and American contributions are promised. Italy, France, and Switzerland share an afternoon that will be given to the propagation of the vine and olive. British communications in the Tropical and Sub-Tropical Section will deal with horticultural work in the Dominions and Colonies, whilst America, Russia, and the Dutch East Indies will also contribute in this section. Dr. W. F. Bewley (Cheshunt) and Mr. G. Jacobsen (Norway), both interested in glasshouse propagation, will deal with the subject of the heating of soil in hot beds by electricity; this subject is, perhaps, appropriately placed under the 'tropical' section. Two papers on seeds will be taken in the last session of the Pomological Section, Prof. Work (U.S.A.) discussing scientific problems in connexion with vegetable seeds, and Prof. C. Tschermak-Seysenegg (Austria) discussing "Xenia in Leguminoseae".

THE serious floods that occurred in the neighbourhood of Whitby on July 22–23 last recall to some the disaster of ten years ago at Louth (Lincolnshire), when 22 persons lost their lives and damage estimated to exceed £100,000 was suffered by that town in a thunderstorm of exceptional severity on the afternoon of May 29, 1920. Meteorologically the two disasters were very unlike. In the Louth storm a belt of cold easterly winds over the North Sea opposed the advance of warm and moist southerly winds advancing across England. There was enough sunshine during the morning to raise the temperature of the southerly winds far enough to produce extreme instability, the easterly winds remaining cold owing to the low temperature of the waters of the North Sea, and the result was apparently an upward movement of the forward part of the warmer air stream and a thunderstorm which was estimated to have at one time a diameter of more than 60 miles. The storm lasted only a few hours, but during that time as much as 121 mm. of rain fell at one place near Louth, the final catastrophe

being apparently precipitated by the breaking down of a temporary dam formed of uprooted trees and other debris, which had held up a great volume of water on the outskirts of the town.

THE recent Whitby floods, on the other hand, were the result of prolonged rainfall of comparatively moderate intensity, due to an almost stationary depression off the east coast of England. Strong northerly winds prevailed throughout, and probably gave very much greater amounts of rain on the North Yorkshire moors than at coastal places of low elevation or inland stations referred to below lying to the west of the wettest region, which was probably the Cleveland Hills. The following totals refer to the period 17 h. or 18 h. G.M.T. on July 20 to 7 h. or 9 h. G.M.T. on July 23:

Scarborough	108 mm.	Ilkley	64 mm.
Bridlington	100 mm. (approx.)	Harrogate	57 mm.
Cleethorpes	65 mm.		

It is not clear from the accounts so far available of these floods to what extent floating wreckage may have assisted the river Esk to overflow its banks, but where rainfall representing the equivalent of about ten weeks of the normal precipitation is concentrated into such a short space of time, partial blockage of the normal drainage channels is to be expected. There is no evidence so far of there having been any particularly rapid rate of fall of rain at any one stage, and the amount measured in the night and early morning of July 22-23 just before the weather mended had been exceeded in a like period 48 hours earlier at all the stations mentioned above except Ilkley.

HAVING regard to the stringent financial conditions obtaining at present in Great Britain and their inevitable reflex upon employment, a welcome must be extended to any scheme which will, or even may, promote the utilisation of home products. It is opportune, therefore, to direct attention to the work of the National Benzole Association, the Research Committee of which has recently issued its seventh report. Despite the momentary restriction of work imposed by removal to convenient centralised premises, continued progress has been made in several directions: but the investigation of resin formation in benzoles and the thorough testing of the possibility of stabilising comparatively crude benzoles against resinification during storage and of afterwards utilising such benzoles satisfactorily as motor fuels, have been regarded as of primary importance. This problem of resinification, not being confined to benzole, has consequently interested workers in other fields. Thus, vapour phase cracked petrols contain appreciable amounts of unsaturated hydrocarbons and show a strong tendency to gum formation; moreover, on storage, they rapidly lose the appreciable anti-knock superiority which they possess over straight run petrols.

ALTHOUGH there are certain minor points of difference between the gumming of benzoles and of cracked petrols, in the main, similar conclusions are drawn in the two cases as to the mechanism of gum formation and the possibility of preventing deterioration of motor fuels containing unsaturated hydrocarbons, by the addition of small quantities of certain substances capable of inhibiting the oxidation and resinification of those bodies. More practically, extensive road trials have shown that comparatively crude benzoles, stabilised by the presence of 0·03 per cent of mixed cresols, are little if at all inferior to acid refined benzoles in their freedom from gumming in engines. The chapter is not yet completed, for the effects of the present inhibitor may be rendered void by the presence of small amounts of impurities, accidental or natural.

A SELECTION of the zoological and botanical specimens collected during Lord Howard de Walden's recent expedition to Uganda and the eastern Belgian Congo was exhibited at the meeting of the Trustees of the British Museum held at the Natural History Museum on July 26. The collection, which is the gift of Lord Howard de Walden to the National Collection, is one of the most important accessions received by the Museum of recent years. The expedition left Fort Portal for the Semliki Valley on Feb. 17 last. Collecting was carried out within twenty miles of Lake Albert, and afterwards in a south-westerly direction to the Semliki Valley, crossing over into the Congo on Mar. 7. The route then led up the western escarpment of the Semliki Valley to Mboga and then west into the Ituri Forest. On Mar. 29 the expedition divided, one party proceeding south to Beni, the other going west to the Ituri River. Both parties came out of the Congo via Irumu and crossed Lake Albert into Uganda on the homeward journey during May. Lord Howard de Walden, in addition to spending some time with the expedition in the forest area, made a special trip to the Birunga Mountains lying to the north-east of Lake Kivu, with the object of photographing the eastern gorilla (*Gorilla gorilla beringeri*) and its habitat. The personnel of the expedition to the Ituri and Semliki Valleys, in addition to Lord Howard de Walden and Dr. Avery, consisted of Mr. R. Akroyd, who as well as organising the expedition did valuable work as a collector of the larger mammals, Capt. F. A. B. Holloway, who concentrated chiefly on invertebrates, making a large collection of butterflies and other insects, and Mr. R. W. Hayman, a member of the Museum staff, who specialised on the medium-sized and small mammalia. Two white hunters accompanied the expedition as guides and supervisors of the 'safari'. The mammals collected number 427 specimens, including 67 monkeys, 110 bats, 71 carnivores, 23 ungulates, and 147 rodents. The reptiles and amphibians collected number 65 specimens representing 31 species in all. Many birds and a very considerable collection of invertebrates was also made.

THE complexity of the problem of the adaptation of varieties of farm crops and the value to the practical farmer of the results already obtained by the National Institute of Agricultural Botany were the theme of the address delivered by the chairman of the Institute, Sir Frederick Keeble, at the annual general meeting of the Institute held at Cambridge on

July 25. Choice of variety or strain, Sir Frederick said, is as potent a factor for improvement in the plant world as in the animal; and it has the merit of being the cheapest remedy for some at any rate of the ills of agriculture. The right sort of seed need cost the farmer no more money than the wrong, but there is generally a difference of ten per cent in the results and often very much more. The discovery of the best variety for each of the innumerable combinations of soil and climate which occur in the British Isles is the formidable task to which the Institute has set its hand, and a valuable nucleus of information has already been formed. The fact that in the famous wheat districts of Essex the best-paying varieties are grown on only forty per cent of the area is a measure of the need for extending the investigations and in particular the collection of records from farmers themselves. No more fruitful task, concluded Sir Frederick, could be undertaken by the Ministry of Agriculture than the provision of wide and effective publicity for the knowledge won by the National Institute of Agricultural Botany and kindred institutions. The Director of the Institute, Mr. Wilfred H. Parker, described the manifold ways in which the Institute has set about its work. Co-operation is the keynote of its success, and this is being given generously by universities, agricultural colleges, farm institutes, plant breeders, county agricultural organisers, research institutions, the National Farmers' Union, the National Association of British and Irish Millers, the Institute of Brewing, and numerous other bodies and individuals.

THREE interesting reports are included in the *Journal of the National Institute of Agricultural Botany*, vol. 2, No. 3, namely, those of the trials of spring-sown barleys, spring-sown oats, and maincrop potatoes. Each report marks the end of a series of trials continued over a number of years, and, as such, represents the considered conclusions of the Institute. The barley variety trials were carried out at six different centres, yield, quality of grain and malt, disease resistance, and differential response to intensive manuring being taken into account. Spratt-Archer and Plumage-Archer 1924 are definitely indicated as giving the highest average return per acre, the former variety being most suited to light and the latter to heavy soils. Of the different varieties of spring oats none showed any marked preference for light or heavy land, or, except as regards strength of straw, for land in high or low condition. In general, taking into consideration yield and both feeding and market value of the grain, farmers are advised to grow either Victory or Golden Rain, but if the soil is rich and lodging is likely to occur, Thousand Dollar is more suitable. Abundance is a further good variety, but this should not be grown on rich land. Oat trials were not carried out in the north of England, so that these recommendations should be applied with caution in that district. A large number of varieties of maincrop potatoes were tested at Ormskirk, Kirton, and Truro. Kerr's Pink, Arran Banner, and Majestic are decidedly the best croppers, although as regards earliness Ally has the advantage. All four varieties are, however, recommended. Golden Wonder and King Edward retain popularity on account of their quality, but their yield is inferior to that of the above-named varieties.

IN an authoritative article on "Unemployment" contributed to the July-September number of the *Political Quarterly*, Sir William Beveridge states that the continuance of unemployment does not invalidate the diagnosis of unemployment made by the Poor Law Commission of 1903-9 or the policies adopted in 1909, because these have not been carried through. Unemployment insurance, with all its devices for reducing claims to benefit, has been transformed into unemployment relief. The Labour Exchanges, after a hopeful start, were sunk in a flood of War tasks and post-War doles and they are only now reviving as employment agencies though their special and most needed services of de-casualisation have gone by the board. Sir William Beveridge points out that unemployment to-day contains two new features. A part of it is due to changes in industrial structure. Another part is almost certainly due to disequilibrium between wages and productivity, following the abnormal rise of real wages since the War. A further possibility is that of a permanent shift in the economic balance of the world, transferring industry from the coal of Great Britain to competitive sources of power elsewhere. Effective organisation of the labour market is even more needed to-day than it was twenty years ago. In so far as unemployment to-day is due to permanent changes of industrial structure involving changes of location, rather than to transient depression, it is more important than before to make labour mobile, locally and between industries.

IN a paper entitled "Economic Quality Control of Manufactured Product", presented before the American Association for the Advancement of Science last December, Mr. W. A. Shewhart advocates the use of modern statistical processes in practical manufacturing work, and particularly for judging whether variations in manufactured material are due to chance. The application of statistical methods in commerce and industry was discussed in a leading article in NATURE of Jan. 9, 1926, when it was pointed out that it would be unfortunate if those responsible in practical affairs failed to take advantage of the improved statistical machinery available. It is satisfactory to find that this statistical machinery has been used successfully in connexion with the work of the Bell Telephone System to show where the cost of inspection and of rejections can be reduced; there has also been a consequent improvement in the quality of the articles produced. The author does not describe in detail the statistical methods he used, possibly because he was afraid of lessening the appeal of his paper to practical men who might be confused by statistical technicalities. The paper has been reprinted in *The Bell System Technical Journal* for April 1930 and is well worth reading.

FEW people realise how flourishing the broadcasting industry is in the United States. Last year, more than a hundred million pounds was spent on

radio instruments. Eight years ago there were 60,000 receiving sets; to-day there are about ten million. In England, many who possess good radio sets scarcely ever use them and look forward with indifference to the coming of television. In the United States, however, there are many enthusiasts who are looking forward eagerly to improved methods of broadcasting the older arts and to the introduction of television. In *World-Radio* for July 25 there is an interesting account of the 'radio city' in New York, work on which will start this autumn. It will be built on Manhattan Island and will take all the space between 48th and 51st Streets and Fifth and Sixth Avenues. The estimated cost is fifty million pounds, and as it is intended to be as permanent as a cathedral, it will take three years to complete. Portions of 49th and 50th Streets will become tunnels. A sixty-story tower will rise above the main buildings to house the studios and office suites. This radio city will have four large theatres, the largest being capable of seating 7000 persons, a motion picture theatre with 5000 seats, an auditorium for comedy and another for drama, and probably a great concert hall. In addition, there will be a bank and shops with frontage on Fifth Avenue. A noteworthy feature is the faith which the supporters of the radio city have in the future of television. They believe that all the present experimental difficulties will be overcome in a few years and that sight and sound broadcasting will be transmitted to homes and hamlets all over the American continent and possibly all over the world.

ONE of the developments of British ornithology in recent years has been the identification of northern geographical races of birds, examples of which, captured in Britain, have shed fresh light upon migratory movements. Greater definiteness is likely to be added to knowledge of these movements by the institution of systematic marking of birds in Iceland, from which some useful records have already been obtained. In the July number of *Discovery*, P. Skovgaard, the Danish ornithologist, gives a first account of the recovery of 124 birds out of 4464 ringed. Of these, 86 were captured away from Iceland and 54 in Britain. One cannot help being struck by the great differences in the migratory habit of different birds revealed even by these limited results. Thirty-one widgeon were recovered and twenty-three golden plover, but whereas the former ranged over a wide area in its southern migration, from the eastern coast of North America to central Russia, the latter moved in a narrow path which probably brought every individual within the compass of the British Isles. The value of the results of the Icelandic work is the greater because some of them refer to birds the headquarters of which are confined to northern latitudes. Comments on Skovgaard's data are contributed by E. M. Nicholson.

INFORMATION has been received that the Quebec Public Service Commission has awarded to the Shawinigan Water and Power Company a "certificate of public necessity and convenience" authorising the commencement of operations in connexion with the development of hydro-electric power at Rapide Blanc on the Upper St. Maurice River, for the power rights of which and certain adjacent sites a seventy-five years' lease has just been entered into. The head of water to be developed at Rapide Blanc will be approximately 110 feet, and the primary installation will make provision for the generation of 160,000 horse power, at an estimated cost of about 18,000,000 dollars. The complete installation on this site will be approximately 240,000 horse power, at an estimated cost of 20,000,000 dollars. The Company is under obligation to commence constructional works forthwith and to develop at least 100,000 horse power by July 1933. As soon as 75 per cent of the primary power at Rapide Blanc becomes available, construction on the second site will be begun under similar conditions, as also will third and successive developments. In connexion with the above projects, including power transmission, as much as 94,000,000 dollars will probably be expended and the total power realised is expected to reach 1,208,000 horse power.

A SECOND bulletin on spectrum analysis has just been issued by Messrs. Adam Hilger, Ltd. It refers mainly to quantitative metallurgical analysis, and half of the pamphlet consists of a tabulated summary of recent work of this type, with references to original papers and a statement of the smallest amounts of the materials experimented on which were estimated in a given matrix. Limits of error are occasionally, but not often, given. The technique used in the several investigations is also outlined. Much of the work referred to has been carried out in Messrs. Hilger's laboratories and in other laboratories with which the firm is in touch, and details of some of this work have not yet been published. A bibliography of recent papers on spectrum analysis follows, including a brief summary of each paper mentioned. Special notes are given on the use of the spectrograph in the rapid assay of lead, copper, and zinc for compliance with certain British and American standard specifications with regard to purity. The pamphlet concludes with accounts of sundry metallurgical applications of spectrum analysis, and a note on physiological, pathological, toxicological, and pharmaceutical applications.

A CONSIDERABLE difference in price exists between the native pearl and the 'culture' pearl and yet so far as visual examination goes there is no distinction between them. The native pearl has originated from a haphazard intrusion of some irritant, while man has been responsible for its insertion in the other instance; in both the outer coat is produced by the mollusc in the same way. The disparity in value makes it desirable to have means of ascertaining the nature of the interior of the pearl. Recently Mr. Jacob Vos, the well-known Dutch jeweller, in conjunction with Philips Lamps, Limited, 145 Charing Cross Road, London, W.C.2, has devised an X-ray apparatus for testing pearls. It makes use of the fact discovered by Dr. von Laue that these short waves are interfered with by a crystalline structure, the

character of the resulting figure on a fluorescent screen or photographic plate being dependent upon the symmetry of the structure. In the present instance the genuine pearl shows a characteristic hexagonal figure entirely different from the figure yielded by a ' culture ' or imitation pearl.

THE fifth ordinary general meeting of the Ross Institute and Hospital for Tropical Diseases, Putney Heath, S.W.15, was held on July 9. The Chairman, Sir Charles McLeod, reviewed the work of the year. Sir Ronald Ross, Sir William Simpson, Sir Aldo Castellani, and D. Shaw-Mackenzie have continued their researches, and a new department in charge of Sir Malcolm Watson has been created to deal with malaria and its problems. Short courses for planters on malaria control have been held and much propaganda work on this subject has been prosecuted. The Institute has no endowment fund except a few hundred pounds and is dependent for its income upon contributions from companies and donations and subscriptions, an increase in which is appealed for.

THE Frederick G. Donnan Fellowship in chemistry, tenable for three years at Johns Hopkins University, Baltimore, has been awarded to Mr. Alkin Lewis, of King's College, London.

DR. H. A. HARRIS, assistant professor of anatomy at University College, London, has been awarded the Alvarenga Prize for 1930 of the College of Physicians in Philadelphia for his researches on bone growth.

BY an Order of the Committee of Privy Council, made after consultation with the Medical Research Council and with the president of the Royal Society, Sir Charles Sherrington, Waynflete professor of physiology in the University of Oxford, and Dr. J. A. Arkwright, honorary bacteriologist to the Lister Institute of Preventive Medicine, have been appointed members of the Medical Research Council in succession to Sir Frederick Hopkins and Sir Charles Martin, who retire in rotation on Sept. 30.

DR. H. R. LANG has been awarded the Institution of Petroleum Technologists fellowship for a further period of one year, to continue his researches on "The Determination of the Variation of the Specific Heat of Typical Crude Oil with Temperature etc". This fellowship, of the annual value of £300, is granted for research work in technical and scientific problems which have a direct bearing on the petroleum industry, and applications for the 1931–32 award should be on a form which can be obtained from the Secretary of the Institution, and should be in his hands not later than June 1, 1931.

THE Trustees of the Beit Fellowships for Scientific Research founded and endowed in 1913 by Sir Otto Beit, Bart., have awarded fellowships, tenable at the Imperial College of Science and Technology, South Kensington, for the two years 1930–32 of the value of £250 a year, to the following: Mr. B. W. Bradford, Imperial College, for research upon the electrical condition of hot metallic surfaces when promoting the combustion of carbonic oxide; Dr. G. M. Richardson, for research into the further application of electrometric methods and theory to the study of problems of biological interest; Mr. G. H. Cheesman, for research on the electron distribution and structure of the halogen oxides.

ARRANGEMENTS are again being made this summer under the auspices of Prof. Patrick Geddes for a vacation tour of historical and archæological interest in the Dordogne. The tour will last from Sept. 12 until Sept. 25, of which period one week will be devoted to a stay at Domme for the study of the geography and objects of historical interest of the neighbourhood, and one week will be given to the prehistoric caves in the neighbourhood of Les Eyziès. A special study will be made of the everyday life of the Perigordian in relation to his geographic environment, under the guidance of M. Réclus, and at Les Eyziès M. Peyrony, by permission of the French Government, will act as guide. The cost of the tour will be £16 : 10s. Application for admission should be made to Miss Moya Jowitt, 33 Gordon Sq., W.C.1.

THE ' complete programme ' of the Anthropological Congress to be held in Portugal and summoned for September next by the Institut International d'Anthropologie of Paris, has now been circulated. The proceedings will be divided into four sections: morphological and functional anthropology with ethnology; palæontology with prehistoric archæology; eugenics and kindred subjects; ethnography, including linguistics, folklore, religion, and human geography. The contributions include 36 from Portugal, 11 from France, 8 from Poland, 6 from Spain, 4 from Holland, 3 from Switzerland, 2 from Russia, one each from Belgium, Finland, Canada, United States, and Brazil. Great Britain, Germany, Austria, Italy, and Scandinavian and south-east European countries are unrepresented.

A PRELIMINARY programme has been issued of the seventh annual conference of the Association of Special Libraries and Information Bureaux to be held at New College, Oxford, on Sept. 19 22, under the presidency of Mr. H. T. Tizard, Rector of the Imperial College of Science and Technology. The programme includes general sessions to hear an account by Brig.-General Magnus Mowat of the year's work of the Association, and a paper by Herr A. Schlomann on the organisation of information in Germany. The sectional meetings will deal with the dissemination of information by exhibition and display (Sir Henry Lyons, Dr. F. A. Bather, and others), animal welfare and its dependence on accurate information (Capt. C. W. Hume), the inadequacy of the alphabetical subject index (Prof. A. F. C. Pollard, Dr. S. C. Bradford), surveys and planning (Mr. C. C. Fagg, Mr. G. L. Pepler, Mr. S. K. Ruck), training of students (Mr. G. F. O'Riordan, Mr. B. M. Headicar), technical English (Mr. C. C. Wharton).

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A director of the Rural Industries Bureau—The Director, Rural Industries Bureau, 6 Bayley Street, W.C.1 (Aug. 8). A graduate master for electrical engineering at the

Sheerness Technical Institute and Junior Technical School—The Principal, Technical Institute, Sheerness (Aug. 11). A university lecturer in agricultural chemistry (soil science) at the School of Agriculture, Cambridge University—The Secretary, Appointments Committee, School of Agriculture, Cambridge (Aug. 11). A lecturer in mining electrical engineering in the University of Birmingham—The Secretary, The University, Edmund Street, Birmingham (Aug. 11). Two assistants in the art and industrial division of the National Museum, Dublin - The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, C.8 (Aug. 11). A lecturer and demonstrator in plant pathology at the Swanley Horticultural College—The Principal, Horticultural College, Swanley, Kent (Aug. 11). A professor of pure and applied mathematics at Rhodes University College, Grahamstown—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (Aug. 15). A demonstrator in pathology and bacteriology at the Welsh National School of Medicine—The Secretary, University College, Cardiff (Aug. 23). An assistant lecturer in pharmaceutical subjects at the Leicester College of Technology—The Registrar, College of Technology, Leicester (Aug. 25). An assistant lecturer and demonstrator in physics at the University College of South Wales and Monmouthshire—The Registrar, University College, Cardiff (Sept. 5). Investigators under the British Cotton Research Association for research work in, respectively, the study of air currents in machines and tubes used for transporting cotton and its separation from dust; the correlation between physical and mechanical properties of cotton cloth and its structure; the physical chemistry of cotton and rayon—Dr. E. H. Pickard, Shirley Institute, Manchester (Sept. 7). An engineer (ferrous metallurgist) under the Department of Mines, Ottawa, Canada—The Civil Service Commission, Ottawa, Canada (Sept. 15). A teacher of science and mechanical engineering at the Technical Institute, Ashford, Kent—The Principal, Technical Institute, Ashford, Kent. An assistant master for junior mathematics and science at the Stanley Junior Technical School, South Norwood Hill—The Headmaster, Stanley Junior Technical School, South Norwood Hill, S.E. A graduate assistant master for science and mathematics at the Tottenham Polytechnic Junior Technical School for Boys—The Principal, Tottenham Polytechnic, High Road, N.17. A Samson Gemmell professor of medical pædiatrics in the University of Glasgow—The Secretary of the University Court, The University, Glasgow. A junior male assistant under the Directorate of Ballistic Research of the Research Department, Woolwich—The Chief Superintendent, Research Department, Woolwich, S.E.18. A scientific assistant in the Coastguards and Fisheries Service of the Egyptian Government—The Chief Inspecting Engineer, Egyptian Government, 41 Tothill Street, S.W.1.

Our Astronomical Column.

Periodic Changes of Colour on Jupiter.—Mr. A. Stanley Williams has observed Jupiter assiduously for a period of nearly forty years; in *Mon. Not. Roy. Ast. Soc.* for May, he discusses the question of periodic changes of colour in the case of the two equatorial belts, using observations from 1868 to the present time. He gives graphs which indicate clearly that there is a 12-year cycle in the colour changes. The maximum redness for the south belt occurred about 1873, 1884, 1897, 1912, 1926; that for the north belt about 1868, 1880, 1891, 1903, 1918, 1928. It appears, therefore, that the two hemispheres have maxima six years apart, indicating that the effect is of the nature of a seasonal one. He notes that the material is scanty in the years when Jupiter was far south of the equator; that is, about 1865, 1877, 1889, 1901, 1913, 1925.

Astronomy in South Africa.—The *Cape Times* of June 16 contains an article entitled "South Africa for Astronomers", by Dr. R. T. A. Innes, who recently retired from the directorship of the Union Observatory, Johannesburg. He traces the present astronomical development in that region to Sir David Gill's invitation to European astronomers to visit the Cape more than forty years ago. Prof. Kapteyn's visit there resulted in the formation of the Cape Photographic Durchmusterung; Prof. de Sitter began there the important work on Jupiter's satellites that he has lately brought to completion; he has also concluded an arrangement for Leyden astronomers to visit Johannesburg Observatory and vice versa. Three North American observatories have established branches in South Africa: Harvard has a branch at Bloemfontein; Yale has one at Johannesburg; and Dr. Abbot, of the Smithsonian Institution, has established a solar observatory at Bukkaros near Windhoek, being led to this by advice from Dr. Innes. Allusion is also made in the article to the proposed moving of the Radcliffe Observatory to South Africa. Dr. Steavenson has been testing the seeing at various sites during the present year, using a 6-inch equatorial that was originally constructed for the observation of the transits of Venus in 1874 and 1882. Dr. Innes notes that there are already more astronomers per thousand of the inhabitants in South Africa than in any other country; and the climate is so well suited for observation that "still further increase in their numbers is desirable".

Annual Report of the University Observatory, Cambridge.—The report indicates that work has continued on the same lines as in recent years. The Sheepshanks telescope is being used for determinations of stellar magnitude with a photo-electric cell. Mr. E. B. Moss has devised a new method of measuring the photo-electric current. Four more fields have been measured for the determination of the proper motions of faint stars. Dr. Knox-Shaw has taken colour-index plates at the Radcliffe Observatory, Oxford, to determine the colours of the stars of which proper motions have been found. These have been measured at Cambridge. Many theoretical investigations on variable stars, proper motions, etc., have been carried on by members of the staff and published in the *Monthly Notices* of the Royal Astronomical Society.

Research Items.

Metals and Cosmetics at Ur.—The authorities of the Museum of the University of Pennsylvania have called in the services of a scientific expert, Dr. A. Kenneth Graham, of the Towns Scientific School of the University, to examine and deal with the finds which have been received as their portion of the antiquities obtained by the expedition working at Ur. Notes on some of the technological and chemical results of Dr. Graham's work are published in the *Museums Journal* (Philadelphia) for Sept.–Dec. 1929. While the early bronzes are of a composition and quality that have never been surpassed, the silver and gold are not of a purity that modern methods permit. Their workmanship, especially of the silver objects, is such as to command admiration. Some of the objects, indeed, it would be an achievement for a modern silversmith to produce. One silver bowl, for example, was first cut from a sheet of silver alloy cast in convenient form. In hammering it into the finished shape, at least three to five annealings would be required. Microscopic examination of the silver objects shows that the structure is similar to that of a modern silver article—that of an annealed metal with numerous twinnings indicating previous working by casting and then alternately annealing and hammering. A chemical examination of the cosmetics used by Queen Shubad shows that both eyebrow and lip paint contained a large and dangerous quantity of lead. One sample of the light blue clay contains large quantities of aluminium, phosphate, copper, lead, and carbonate, with traces of iron, calcium, and silica. Probably it is powdered turquoise. A black powder similar to antimony or 'kohl' contains a large amount of manganese and lead with a small quantity of copper, aluminium, phosphate, carbonate, silica, and iron. The last six were evidently present as turquoise. The black colour was due to the manganese, the black oxide of which occurs naturally as pyrolusite. The lead and carbonate must have been added intentionally. The oxides of lead when mixed with the above minerals give shades of brown, red, and purple, and it is probable that in early times a greater variety of colours was preferred to the red and black of to-day.

Reptiles and Amphibians of the Malay Peninsula.—Since Dr. G. A. Boulenger published his account of this fauna in 1912, collections have been made, especially in the northern part of the Peninsula, which have added considerably to the old list. The additions include 1 species of turtle, 16 of lizards, 12 of snakes, and 18 of amphibians, and these, with a revision of the old names and identifications, Dr. Malcolm A. Smith publishes in a supplement to Boulenger's work (*Bull. Raffles Mus.*, Singapore, No. 3, 1930). The supplement is furnished with useful keys to the genera and species, and a new feature is a key to the characters of the tadpoles of the amphibia. Smith notes amongst the reptiles and amphibians a very marked discontinuous distribution, a number of species which are to be found in the northern part of the Peninsula and in the islands of the Malay Archipelago being absent from the southern portion of the Peninsula. A similar discontinuity has been observed in the distribution of certain mammals and birds, and the indication is that some very general but still undetermined influence must have been at work over the territory.

Luminosity in a Squid.—The small Japanese squid, *Watasenia scintillans*, is famous for the brilliance of its phosphorescence. This is due to three types of luminous organs, all of different construction, skin organs, eye organs, and tentacle organs, but all possessing certain granules which are situated in the luminous tissue. The rôle of the granules has given rise to differences of opinion. Shima considered them to be luminous symbiotic bacteria, Hayashi thinks they play an important part in luminescence, and now Teijiro Kishitani has re-examined the light organs of *Watasenia* particularly with the idea of deciding whether photo-bacteria are present or not (*Annot. Zool. Japon.*, vol. 11, p. 353, 1928; just received by NATURE). His attempts to isolate bacteria from the luminous organs on culture media failed, and smear preparations showed that the rod-like granules behaved differently from bacteria with various stains. Further, the rods were never seen in process of dividing and they broke into minute pieces under slight pressure applied to the cover-glass. The author concludes that the granules are not luminous symbiotic bacteria, of which he found no trace, but the question as to whether the spindle-shaped granules and rods function merely as reflectors, or may be crystals of luciferin (such as occur in the luminous organs of the fire-fly) and of importance in the production of light, remains unsettled.

Percoid and Related Fishes.—Under the title of "Notes on Percoid and Related Fishes", Mr. Henry W. Fowler (*Proc. Acad. Nat. Sci.*, Philadelphia, vol. 81, 1929) enumerates a large number of fishes contained in the general series of the Academy. Upwards of 2000 specimens belonging to nearly 300 species are recorded, and the new sub-genus Cheiroxenichtys is described to embrace *Xenichthys agassizii* Steindachner, being distinguished chiefly by its long pectoral fin, nearly as long as the head, and its uniform silvery coloration. These records, in several cases accompanied by descriptive notes, which are mostly from the American coasts and West Indies, are of value in extending our knowledge of the distribution of many rare fishes.

Wild Populations of *Plantago maritima*.—The analysis of the populations of a particular species occupying various natural habitats is a subject offering considerable scope for investigation. Dr. J. W. Gregor (*Jour. of Genetics*, vol. 22, No. 1) has made such a study of the plants of *Plantago maritima* from one small locality on the east coast of Scotland. This common coastal plant is found also in certain inland locations, especially on mountains. Mr. Gregor shows that, as regards one character, the individuals of the species range from decumbent to erect (5 types). The plants growing on an exposed rock just above high tide were more dwarfed and more decumbent than those growing on an adjacent grassy slope. Plants grown from seeds of the two populations under uniform culture conditions showed significant mean differences in such features as height and relative spread. The rock-population had a larger percentage of low-growing forms, but the grass-population contained no type which was not also present in the population from the rock habitat. The cultures indicated that the latter population had been more modified by its original environment than the former. They also showed a phenotypic parallelism between the modifying effect of the environment on wild populations and on the growth-forms present in the cultures. There was variation in succulence of the cultivated forms, and it was shown that, by watering plants with a 3·5 per cent solution of sodium chloride, the fleshy habit of the leaves could be induced.

Permian Flora of the Grand Canyon, Arizona.—Monograph 405 of the Carnegie Institution of Washington contains a complete and well-illustrated

account of an interesting Permian flora, found in the Hermit shale of the Grand Canyon, Arizona, and under investigation by the author, David White, since its first discovery in 1915 by Prof. Schuchert of Yale. This flora is interesting as the latest Palæozoic flora as yet known in America and particularly because, composed mainly of plant forms previously unknown, it presents a unique aggregate of western European elements with others which show definite points of contact with the Gondwana flora. In this flora the herbaceous plants, including the Pteridosperms on one hand and the shrubby or arborescent Gymnosperms on the other, are fairly well balanced; the author recognises no forms as ferns, as yet. The apparent absence of the Calamariales may be due to the arid conditions under which this flora developed. The most characteristic plants appear to be a group which the author regards as Pteridospermic, with affinities with the Gondwana plants, and to which he gives the name of *Supaia*; they are characterised by once bifurcated fronds, in which the strongly asymmetrical divisions, facing each other, *vis-à-vis*, are simply pinnate or pinnatifid. The Gymnosperms are strongly represented in this flora.

The Upper Atmosphere.—The *Journal* of the Royal Astronomical Society of Canada for April contains an article by Dr. W. E. Harper on the upper atmosphere. He recalls the evidence for rapid movements at a high level that was afforded by the eruption of Krakatoa in 1883: the dust of the explosion was projected to a great height, and carried rapidly round the whole earth, reaching higher latitudes in successive revolutions. He discusses the presence of ozone in the upper atmosphere, and its useful effect in absorbing the short ultra-violet rays from the sun; he notes that an excessive supply of these rays would be injurious both to animals and plants. The ozone layer is thickest in the spring, and then slowly and continuously diminishes to a minimum in winter.

Air as a Thermal Insulator.—The *Gesundheits-Ingenieur* has published at 5 marks a 26-page pamphlet by Drs. W. Mull and H. Reiter, "Der Warmeschutz von Luftschichten", which gives the results of their measurements of the thermal insulating properties of layers of air in buildings. For dwelling-houses they find that the best thickness of the air layer in a cavity wall is 5 cm. if it is limited to a single layer. Multiple layers give better insulation than a single layer of the same total thickness. The rate of transmission of heat through an air layer depends on the radiation constant of the surfaces bounding the layer, on the mean temperature of the air, on the difference of temperature of its surfaces, on its thickness, and in the case of a vertical layer on its height.

New Swedish Magnetic Observatory.—Capt. A. Reinius, Director of the Swedish Hydrographic Service, in 1927 obtained State sanction for the institution of a Swedish magnetic observatory, primarily as a base station for the magnetic survey, but also for purely scientific work. An account by G. Ljungdahl of its initiation, buildings, and equipment is included in the first publication of the observatory (*Ergebnisse der Beobachtungen des magnetischen Observatoriums zu Lovö, Stockholm*) together with the detailed data for the first year of working, 1928, edited by S. Aslund. On account of its high latitude (59°) the institution of this observatory is an important and valuable step, and its usefulness is the greater in that it publishes hourly values of the magnetic elements. It is situated 14 km. from Stockholm, on an island in the State forests: both the absolute and the variation instruments are above ground, the latter being in an unheated concrete chamber covered with a great thickness of earth, and shaded by trees; the change of temperature inside it, from day to day, does not exceed 0·2°. The instruments consist of a Carnegie Institution pattern of combined magnetometer and earth-inductor, for absolute measurements, and two sets of variometers, of normal and reduced sensitiveness: the *Z*-variometer is of the type invented by Dr. La Cour, and installed by him at Rude Skov and Godhavn (Greenland).

Light Scattering in Liquids.—A paper by R. M. Langer and W. F. Meggers in the May number of the U.S. Bureau of Standards *Journal of Research*, on the scattering of light by liquids, raises some important questions in connexion with the interpretation of Raman spectra. It is pointed out that the quantum theory of the change of wave-length in scattering does not necessarily require that the same characteristic frequencies of a substance should be effective both in scattering and in infra-red absorption, but that, on the contrary, data obtained by the two methods would rather tend to be complementary. In the earlier experimental work, much of the apparent agreement between the two sets of measurements was fairly obviously forced. These investigators, from their own measurements of the changes in frequency of light scattered by benzene, toluene, chloroform, and carbon tetrachloride, which appear to be as accurate as any yet made, conclude that the original idea of a direct correspondence between absorption spectra and shifts in scattered light is completely discredited, and that it is futile at present to attempt a complete interpretation of the modified lines scattered by liquids, or to draw any final conclusions as to molecular structure from them. Only the systematic accumulation of trustworthy data for scattering substances belonging to distinct chemical families, and especially the investigation of the simpler molecular structures, can be expected to give clues to the correct explanation of light scattering in transparent media.

Radio Beacons and Aircraft.—The U.S. Bureau of Standards and the Department of Commerce in the United States have developed a visual signal-indicating device to guide mail aeroplanes over the Appalachian Mountains. An aural beacon system is at present in use. Coded signals are picked up by the head telephones, but this is found to put a great strain on the pilot as he has to concentrate his thoughts when listening and must wear the telephones practically all the time. The new device consists of two vibrating white reeds. These will be placed on the instrument boards of the New York to Cleveland mail aeroplanes. The aviator can tell whether he is on the right path or not by watching the reeds. If the reed on the left vibrates most, he has turned off to the left of his course. Similarly, if the amplitude of the vibrations of the right hand reed is greater, he will know that he has veered off to the right. When both vibrate alike the aeroplane is on the right course. The searchlights which are installed at ten-mile intervals along the route will still be used. When the visibility is good the lights can be readily followed, but at present in fog, rain, or snow the ground and the searchlights are invisible and the pilot has to rely entirely on the aural signals. A recent test flight from Detroit to Washington was made almost entirely by beacon signals and not by maps. We understand from the *Daily Science News Bulletin* for May 9, issued by Science Service, Washington, D.C., that there is no prospect at present of attempting 'blind' landings. The path of the aeroplane with the help of the beacon

guide brings the pilot near enough to the landing field for him to see the ground lights and so make a descent by sight.

Valve-maintained Quartz Oscillators.—Radio engineers are looking forward to a much more extended use of quartz oscillators in the immediate future, not only for maintaining the frequency of the waves emitted from broadcasting stations constant, but also for making receiving sets very selective. In a paper read to the Institution of Electrical Engineers on Mar. 5, and recently published in the Institution's journal, J. E. P. Vigoureux, of the National Physical Laboratory, describes an investigation he has carried out for the Radio Research Board on valve-maintained quartz oscillators. The combination of a quartz resonator and a valve circuit is called a quartz oscillator. The frequency of the oscillator depends mainly upon the natural frequency of the quartz resonator, and when the temperature is constant they are both nearly constant. The former can be varied, however, by altering the air-gaps of the resonator, that is, the air-gaps between the quartz and the two electrodes of the resonator, or by varying the constants of the plate circuit or the interelectrode capacities and inductances. These variations have been studied both theoretically and experimentally. The theoretical treatment has been rendered possible by the experimental work of Dye, who has shown that the quartz oscillator can be replaced by an equivalent electrical circuit. The equivalent circuit consists of an inductance, a resistance and a capacity connected in series, the whole being shunted by a second capacity. Making this substitution, the problem reduces to one which can be solved by ordinary mathematical methods. Formulæ are deduced which give the conditions for the maintenance of oscillations. It is shown also how the amplitudes of the oscillations depend on the values of the component parts of the circuit.

Corrosion of Steel by Concrete.—Special Report No. 15 of the Building Research Department of the Department of Scientific and Industrial Research (H.M. Stationery Office, 6*d.* net) deals with the corrosion of steel by breeze and clinker in concrete. It is shown that coal residues are definitely undesirable ingredients in concrete which is to be placed in contact with steel, since they cause corrosion. In the interests of safety it would seem desirable to abandon altogether the use of breeze and clinker aggregates for concrete in contact with steel.

Abrasives.—Report No. 699 of the Department of Mines, Canada, deals with artificial abrasives and their manufacture, and abrasive products and their uses. Three parts previously published dealt with siliceous abrasives; corundum, emery, and diamond; and garnet, respectively. The manufacture of grinding wheels, sandpaper, steel wool, and other abrasives is described in detail, as well as their principal industrial applications. Although the report contains a very extensive bibliography, much of the information has not previously been published. Copies of any of the parts may be obtained on application to the Director, Mines Branch, Department of Mines, Ottawa, Canada.

Dipole Moments.—A monograph by J. W. Williams, entitled "Molekulare Dipolmomente und ihre Bedeutung für die chemische Forschung", being one of the parts of the "Fortschritte der Chemie, Physik und physikalischen Chemie" (Berlin: Gebrüder Borntraeger), gives a useful condensed account of a subject which is now attracting a good deal of attention, the fundamental theories and the experimental results being dealt with. Particular attention is directed to the determination of molecular structure from dipole moments. It may be noted that the structural formulæ which have been used by chemists for half a century appear in general to be confirmed by the new investigations. The relations of the results to those of other fields of investigation are briefly considered and, since the mathematical apparatus is reduced to a minimum, this clearly written monograph of sixty-five pages should prove of great interest and utility to chemists who have found the more ambitious treatises too abstruse for their requirements.

Thermal Expansion of Glass.—The March number of the *Journal of the Society of Glass Technology* contains two papers on the thermal expansion of glass, by Prof. Turner and F. Winks. It was found by Peters and Cragoe in 1920 that there is a range of temperature, called the critical or annealing range, over which the thermal expansion was several times as great as that in the range lying between the ordinary temperature and the lower critical temperature. The first paper summarises investigations made during the past five years. Reproducibility over the whole range of temperature up to the softening point was almost attained with a number of glasses. The influence of lack of homogeneity on reproducibility was found to be small. The effects of tension, composition, and heat treatment were investigated, and a general analysis of the thermal expansion curve is given. The critical point, when the rate of expansion alters abruptly, was not always found, and the normal expansion curve may undergo changes of direction at temperatures below the critical point. In a discussion on the nature of glass, it is suggested that a 'vitreous state' of matter, as well as liquid and solid, should be recognised. The second paper deals with the expansions of a series of sodium metasilicate-silica glasses. The results are discussed in detail.

Conductivity of Solid Salts.—In previous experiments on the effect of temperature on the electrical conductivity, k, of solid halides of sodium and potassium, T. E. Phipps and co-workers found that the curves of $\log k$ plotted against $1/T$ usually exhibited two distinct slopes, which were interpreted as follows. It is assumed that the conductivity of a solid is proportional to the numbers of ions in its lattice which have an energy greater than a certain threshold value, and the slope of the curve then measures the heat of liberation which the conducting ion or ions must acquire in order to participate in the conduction. In the April number of the *Journal of the American Chemical Society*, Ginnings and Phipps show that the curves for lithium halides are similar. The slopes found in the lower temperature range measure the heats of liberation of the metal ion in the lattice, and those at the higher temperatures the combined heats of liberation of metal and halogen ions. Transference experiments had shown that, in the case of sodium chloride, only the sodium ion takes part in the conduction process over the temperature range of the lower slope, while in the higher temperature range both ions contribute to the conduction. The melting-points of highly purified lithium halides were found to be: LiCl, 606°; LiBr, 551°; LiI, 467°. The heat of liberation of either alkali ion or halogen was smaller the lighter the alkali metal in a series with a common halogen. In a series with a common alkali metal, the heat of liberation of either ion is greater the lighter the halogen ion. A linear relation between the heat of liberation and the absolute melting-point is indicated.

Statistics of the Universities of Great Britain.*

WITH the current academic year has ended the five years for which the Parliamentary grant for universities and university colleges in Great Britain was fixed at its present figure, £1,550,000. Since 1919 the duty of advising the government of the day concerning the financial needs of these institutions has been discharged by the University Grants Committee, and this body has accordingly been engaged during the past twelve months in visiting them. In the light of the personal knowledge thus acquired and the various returns annually submitted to it, the Committee has prepared a review of the period 1923–24 to 1928–29 and a report on present needs and problems. These documents have now been published, together with the customary statistical tables for the year 1928–29.

The total number of full-time students of both sexes last year was 44,309. The total shown in the returns for 1923 24 is 43,025, but this includes 1742 students of a special type not represented in last year's total, namely, those aided to take university courses under the Government scheme for the higher education of ex-Service men. Deducting those, the increase in five years was 7 per cent. Taking men students alone the increase was 11 per cent, the number of women students showing a decrease from 12,962 to 12,899, or from 31·4 per cent of the total of both sexes to 29·1. Dissection of the total enrolment figures according to the various subject groups discloses a marked contrast between an upward trend of enrolment in the arts faculties, including theology, fine art, law, music, commerce, economics, and education, and a downward trend in medicine (including dentistry) and technology (including engineering, applied chemistry, mining, metallurgy, architecture, etc.), and comparative stagnation in pure science and agriculture (including forestry, horticulture and dairy work):

	1923-24.	1928-29.	
Arts . .	18,981	23,625	+ 4644
Medicine . .	10,997	8,387	- 2610
,, women only	2,020	1,108	- 912
Pure Science .	7,402	7,377	- 25
Technology .	4,709	4,082	- 627
Agriculture .	856	838	- 18

The 'swing-over' from medicine and technology to arts was widespread but was most pronounced in Scotland, where the percentage of arts students rose from 44·2 to 59·3 (men 31·4 to 47·1; women 70·7 to 83·9), and there were corresponding declines in the proportions of students in other subject groups, and especially in medicine (men 38·1 to 29·3; women 17·9 to 7·4) and technology (men 17·8 to 10·5; women 0·5 to 0·4). It is accounted for thus: "The stationary position of the Pure Science group and the fall in the Technological group are no doubt due to the continued depression in many industries. The decreased number of students in the Medical group, which includes Dentistry as well as Medicine, seems to be the result of a reaction which followed the abnormally large entry of medical students just after the war." "The main reason for the growth in the Arts group is no doubt to be found in the attraction exercised, during a period of bad trade and restricted opportunities in other professions, by the securer and greatly improved prospects of the profession of teaching; in Scotland the general tendency has been intensified by the official requirement that only graduates can now normally be admitted to the Provincial Centres for training as men teachers."

Each of these factors is mentioned in an article in the April number of *The Universities Review* on overcrowding in the German universities. There, however, the students of the *technischenhochschulen*, corresponding more or less to the technological faculties of the universities of Great Britain, form nearly twice as large a proportion of the total number of university students as in Great Britain, and scientific education is very widespread. Whatever its causes, the falling off in the numbers of students in the scientific departments of British universities cannot but excite misgivings on the part of all who believe in the importance for our future welfare of "integrating into the intellectual structure of society", as J. B. S. Haldane puts it, "the scientific ideas which have furnished its material structure". In the part of the report relating to careers open to graduates (see below) the Committee indicates reasons for anticipating an increase in the enrolments in technology and pure science.

In the following tables universities are arranged in order of the numbers of their full-time students in 1928-29, first in all faculties and then (omitting many of the smaller enrolments) in the above-named subject groups severally. It will be seen that London heads the list in every case except arts and agriculture, in which, respectively, Oxford and Reading rank first, that Cambridge comes second in every case except medicine, and that Glasgow is third in every case except agriculture. The increase (+) or decrease (-), in comparison with the corresponding figure for 1923 24 is given in brackets:

All Faculties.

* University Grants Committee. Report, including Returns from Universities and University Colleges in receipt of Treasury Grant, Academic Year 1928–29. Pp. 74. (London: H.M. Stationery Office, 1930.) 3s. 6d. net.

The number of full-time advanced students (as distinguished from those pursuing courses for first degrees or diplomas) shown in the returns for 1928–29 is 2082, including 374 women. The following table compares their distribution over the various subject groups with the distribution of the total number of full-time students :

	All Students.	Advanced.
Arts . . .	53·3 per cent.	39·1 per cent
Medicine . .	18·9 „	4·8 „
Pure Science . .	16·7 „	42·6 „
Technology . .	9·2 „	11·4 „
Agriculture . .	1·9 „	2·1 „

Two-thirds of the total number of these advanced students were at work in London (696, including 246 at University College and 207 at Imperial College), Cambridge (378), Oxford (185), and Manchester (153). In the Scottish universities there were 182, and in the Welsh 97. Of the individual subjects by far the most popular among advanced students are chemistry (453) and physics (185).

The universities of Great Britain are drawing students from other countries in increasing numbers : so much so that more than half the total increase during the quinquennium in the number of full-time students is attributable to this source. Those from other parts of the British Empire numbered 2809 in 1928–29, being 14 per cent more than in 1923–24, whilst those from foreign countries numbered 1581, showing an increase of 26 per cent.

The financial resources of the universities of Great Britain are exhibited in the returns for 1928–29 in some detail. The incomes amounted in the aggregate to £5,174,510, and were derived from : (*a*) Parliamentary grants, 36 per cent ; (*b*) fees, 31 per cent ; (*c*) endowments, 14 per cent ; (*d*) grants from local authorities, 10 per cent ; and (*e*) other sources, 9 per cent. Capital benefactions received from other than Government sources in the course of the past five years amounted to more than £5,550,000, in which total are included gifts by corporations and individuals in the United States of America amounting to £1,700,000, nearly one-third of the total. Excluding these American contributions, the benefactions in five years amounted to less than one-sixth of the amount received as gifts and bequests in one year by universities and colleges in the United States, and about one-fourth of the amount received in one year by sixteen of the most favoured of them. The aggregate income is about half that of the universities and colleges of the State of New York. Sources of American university incomes are : (*a*) United States Government grants, 5 per cent ; (*b*) fees, 32 per cent ; (*c*) endowments, 16 per cent ; (*d*) grants from State or city governments, 26 per cent ; (*e*) other sources, 23 per cent.

Since figures for Oxford and Cambridge were not available at the beginning of the quinquennium on a sufficiently comparable basis to be included in the University Grants Committee's standard tables of financial statistics, the Committee's comparative statements of income and expenditure in 1923–24 and 1928–29 leave those two universities out of the reckoning. The comparison shows a growth of total income from £3,592,936 to £4,210,710, approximately 17 per cent. Rather more than half of the increase is under the head of Parliamentary grants. Income from endowment shows an increase of £72,822 (18 per cent), from donations and subscriptions £23,989 (26 per cent), from local education authorities' grants £92,926 (22 per cent), and from fees £44,267 (4 per cent). The proportion of Parliamentary grants to total income rose from 35·4 to 37·8 per cent, and that of fees to total income fell from 33·7 to 29·8 per cent. The only institutions deriving more than half of their income from Parliamentary grants are three of the London colleges, two Welsh colleges and Reading. Oxford and Cambridge get, respectively, 30 and 25·6 per cent of their incomes from this source. The Committee concludes an examination of the question of the increasing dependence of universities on State aid with the observation that the large increase in the grants given by the State five years ago has served to stimulate rather than to discourage the generosity of the other bodies and individuals to whom the universities have to look for support.

That dependence is about to be further increased by the raising of the amount of the annual Treasury subvention from £1,550,000 to £1,800,000. The report stresses, in this connexion, the fundamental importance of the teaching staff and the library and expresses the hope that one of the first uses to which the universities will put any increase they may obtain in their annual incomes will be to improve the lot of teachers of the senior lecturer class, many of whom find themselves in a serious plight. In discussing the position and prospects of the junior staff, the Committee directs attention to the barriers which stand in the way of their obtaining posts in secondary schools. These barriers have arisen through the operation of the new salary scales for teachers in schools and, in Scotland, the requirement that, whatever their previous experience, all applicants for such posts must have had a course of professional training for school work. This is, the Committee thinks, unfortunate, as the universities and schools both stand to gain by such exchanges.

In the part of the report relating to the careers open to graduates we find : "The need for a much more extensive application of scientific research to industrial practice is becoming more clearly realised every day, and the scientific departments of the universities are the obvious training grounds for men and women qualified either to undertake work on the fundamental problems, which are the field of the Industrial Research Associations established with State assistance, or to devote themselves, in the service of individual firms, to the improvement of particular industrial processes. . . . Some years ago it was common knowledge that the 'market' for chemists was seriously overstocked, and that many men with first-rate qualifications in Pure Chemistry were unable to obtain suitable employment, but we gather that the market has of late greatly improved, under the enlightened influence of the great combine over which Lord Melchott presides, and that though the output of students trained in Pure Chemistry continues to be, perhaps disproportionately, large, it is now being successfully absorbed. . . . There is evidence of an increasing range of demand for men who have had a good training in Physics, Geology, Biology, and such applications of Chemistry as Chemical Engineering or Fuel Technology."

The demand for university graduates is, moreover, we are told, extending rapidly to the administrative side of industry and of business generally. While it has hitherto been rare in Great Britain, though common in Germany, to give to men of high technical qualifications a place on the directorate of an industrial firm, many of the large industrial organisations are coming to look more and more to the universities for men of good general education and balanced character for the responsible administrative work which the vast range of their operations now involves, and even the smaller concerns seem more willing than they were to have recourse to the same recruiting ground.

The Italian Earthquake of July 23.

SINCE Jan. 13, 1915, when Avezzano and other towns in central Italy were ruined, there has been no earthquake in the peninsula so destructive as that which visited the provinces of the Basilicata and Campania shortly after 1 A.M. (0 A.M. Greenwich mean time) on July 23. The latest estimate of the number of persons killed is 1883, while the buildings of 34 communes are said to have been seriously damaged. The epicentre, which seems to be close to the town of Lacedonia, lies about 65 miles slightly north of east from Naples.

The area of slight damage, as at present known, is bounded by a curve that is roughly in the form of an ellipse directed west-north-west, 39 miles long, 16 miles wide, and containing about 490 square miles. The places that have suffered most are Villanova, Aquilonia, and Lacedonia, lying within a district about 19 miles long and 90 square miles in area, in the north-west half of the former curve, and Melfi and the surrounding towns near its south-east end. The principal centre apparently lies midway between Villanova and Lacedonia, but there may have been a secondary centre close to Melfi about 20 miles to the east-south-east. The shock was strong enough to damage a few houses in Naples and to have been felt in the province of the Marches, and even so far as Rome, so that the total area disturbed may contain about 95,000 square miles, or roughly that of the Hereford earthquake of 1896. The first movements were recorded at Kew at 0 h. 12 m. 11 s. and at Helwan (Egypt) at 0 h. 12 m. 42 s.

The province of the Basilicata is one of the most unstable regions in Italy. The great Neapolitan earthquake of Dec. 16, 1857, so admirably investigated by Robert Mallet, disturbed chiefly the southern part of the province. Mallet, from observations on the direction of the shock, placed the epicentre near the village of Caggiano, which lies about 34 miles to the south of that of the recent earthquake, but the principal centre was probably near Montemurro, 24 miles south-east of Caggiano. More closely connected with the recent earthquake are the Avellino earthquake of Sept. 8, 1694, and the Melfi earthquake of Aug. 14, 1851, described by Dr. Mario Baratta in his valuable work "I terremoti d' Italia" (pp. 173-181, 407-410; 1901). In 1694, the number of persons killed was 3571. The area of destruction was of unusual size, extending about 50 miles north-west from Potenza. In 1851, 628 persons lost their lives, and the meizoseismal area was small, not more than 11 miles in length, with its centre close to Melfi. The area strongly shaken by the recent earthquake thus includes that of the Melfi earthquake and lies along the northern boundary of that of the earthquake of 1694.

C. DAVISON.

The Skull of Peking Man.

DR. DAVIDSON BLACK'S interim report on the skull of *Sinanthropus* found at Chou Kou Tien at the end of last year was presented at a session of the annual meeting of the Geological Society of China held on Mar. 29 last, and has now been published in the *Bulletin* of the Society. It is illustrated by six plates which reproduce the natural size of the photographs of the frontal, right and left laterals, occipital, vertical and basal views of the skull.

The whole external surface has now been freed from travertine, with which, however, the interior is still filled. During the preparation of the skull, the major parts of parietals and the whole of the frontal bone were separated from the stone filling; but these were replaced for the purpose of the photographs, which show the parts in approximately correct relation. A table of measurements is given which supplements and corrects those of the previous report, but they are themselves only approximate and subject to correction.

The skull, doubtfully identified as female, has a glabello-occipital length of 192 mm. and a breadth of 132 mm. (?), the maximum breadth which falls between the supra-mastoid regions of the temporal bones being *circa* 144 mm. The least frontal breadth is 83 mm. (?) and the greatest frontal breadth 102 mm. (?). The auricular height is 97 mm. (?) The parietal eminences are quite well developed; but the sides of the cranial vault below them are markedly inclined toward one another. The bones are much thicker in certain regions than was supposed (for example, below the lambda). They do not show the excessive thickness of the Piltdown skull, but they are much thicker than in modern man.

One of the most, if not the most interesting point brought out by Dr. Black in this interim report is the bearing of certain unique morphological features which were not apparent at the earlier stages of preparation. It is now clear that what was previously considered to be a markedly developed post-glenoid process is seen to be a very peculiarly developed tympanic portion of the temporal. In the massive parts of the tympanic elements, the posterior moiety is developed to form a prominent crest which extends inward to the base of the minute styloid process, while the anterior portion of the tympanic bone forms a massive rounded wall limiting the mandibular fossa and rising abruptly immediately behind the petro-tympanic tissure. The glenoid cavities are thus obliquely placed deep fossæ, the visible floors of which are formed wholly from the zygomatic elements of the temporal bones. The mandibular fossæ are thus wholly hominid in character.

It is, however, extremely interesting to note that for the first time among hominids is found a stage of development much more archaic than in Neanderthal man and at the same time in certain features recalling some of the relations characterising this region in anthropoids, such, for example, as the chimpanzee. Dr. Black recalls that both Boule and Martin in reference to the La Chapelle and La Quina skulls respectively have pointed to certain resemblances to the chimpanzee in that region, placing them somewhat intermediately in type between that form and *Homo*. The Peking skull in this respect may be termed pre-Neanderthaloid, and in the hominid scale may be not far removed from the type which evolved both the extinct Neanderthal and the modern *Homo sapiens*.

University and Educational Intelligence.

LEEDS.—The Council of the University of Leeds has elected Dr. F. Challenger to the chair of organic chemistry shortly to be vacated by Prof. C. K. Ingold. Dr. Challenger, who is at present senior lecturer in chemistry at the University of Manchester, is a graduate of London and Göttingen. Throughout his career he has been actively engaged on research work; amongst the subjects to which he has given attention are the organo-derivatives of bismuth, the organic chemistry of sulphur and the technology of mineral oils, the production of acids such as citric and oxalic by biological processes, and the chemistry of petroleum.

MANCHESTER.—Applications are invited for the Amy Henrietta Worswick fellowship for the investigation of the causes and treatment of rheumatoid

arthritis. The annual value of the fellowship is £150. The tenure will be for one year with the possible renewal for a second year. Applications must reach the registrar by, at latest, Oct. 15.

IN schools in the United States of America are enrolled more than half of the total population of ages 15, 16, 17, and 18 years. Twenty-five years ago the proportion was only one-tenth. Some account of this remarkable growth is given, with voluminous statistics of public high schools in 1927–28, in *Bulletin*, 1929, No. 35, of the United States Office of Education. The rapid addition of large groups of pupils of types very different from those with which the traditional high school had been accustomed to deal necessitated radical changes, including an expansion of curricula from a strictly limited group of subjects (English, Latin, Greek, French, German, algebra, geometry, physics, chemistry, and general history) to very varied assortments of some two hundred and fifty subjects, of which many are definitely vocational and industrial in character. Other notable changes accompanied the 'junior high school' movement, started about the beginning of the present century. This has led to reorganisations, affecting nearly half of the total public high school enrolment, the main features of which are the differential treatment of the age group 16, 17, and 18 years (senior high school) and the absorption in junior high schools or departments of pupils of the higher grades (ages 13-14 years) of the primary schools. The place of sciences in the high schools seems to be a diminishing one, except as regards biology, hygiene, and sanitation. In 1910, eighty-two per cent of pupils were studying some science, in 1915 sixty-four per cent, in 1928 sixty-one per cent. The drop in numbers studying physics, from fifteen to seven per cent, is specially noticeable. Physical geography and physiology also show important decreases, and geology has almost disappeared from the high school programmes.

FROM the University of Leeds we have received two reports on its Clothworkers' Departments. They are of more than ordinary interest by reason of the highly important developments of research resulting from a special grant of £3000 by the Clothworkers' Company. A report on these developments describes in some detail researches conducted (i) under the direction of Mr. J. B. Speakman in the plasticity of wool, influence of plastic flow on the affinity of wool for water (already reported in NATURE of Sept. 14, 1929), rigidity of wool and its change with adsorption of water vapour, elastic properties of wool in water at high temperatures, examination of the fine structure of wool by X-ray analysis, thermal conductivity of and transmission of water vapour through textiles, and physico-chemical properties of wool fat; (ii) under Mr. W. T. Astbury's direction, some applying new X-ray methods of investigation inaugurated by Sir William Bragg to the problems of fibres in general and of wool and hair in particular, and others aiming at the solution of definite technological problems relating to the uniformity of yarns, the significance of fibre lengths, etc. In the Department of Colour-Chemistry and Dyeing, the progressive decline which has characterised enrolments of the past decade was followed last year by a considerable increase and the demand by industry for graduate students trained in the Department exceeded the supply available. Huddersfield Technical College also reports heavy enrolments in its dyeing department and an important growth of research work in all its departments, especially in colour chemistry and chemistry, and almost complete success by its appointment department in placing students in suitable positions.

Historic Natural Events.

Aug. 3, 1879. Hailstorm near London.—Over an area seven miles long and two miles broad, between Kingston and Ealing, violent hail fell. The stones were up to six inches in circumference, broke all glass exposed to them, pierced holes in zinc and slate roofs, and knocked out of shape the anemometer cups at Kew Observatory. The thunder and lightning were continuous from 9 P.M. to 3 A.M.; at Cambridge at 3 A.M. there were 120 flashes per minute.

Aug. 3, 1883. Cloudburst on Ochil Hills.—During the afternoon a violent storm burst on the Ochil Hills between Dollar and Alva. A flood of water poured down a deep narrow valley into Alva, the main street becoming deeply flooded in three minutes. Bags of flour and casks of butter were floated a distance of 100 yards from a baker's shop.

Aug. 4, 1577. Damage by Lightning in Suffolk.—On Sunday, Aug. 4, between 9 and 10 A.M., the parish church of Blythburgh, in Suffolk, was struck by lightning, which burst through the wall, struck almost a yard deep into the ground, and knocked down about twenty people who were on that side of the church. It then broke the door and badly damaged the steeple, breaking the timber and the bells. The people that were stricken down were found still grovelling more than half an hour afterwards, and two were dead. About the same time the parish church of Bungay, nine miles from Norwich, was also struck, the wire and wheels of the clock being broken and two men in the belfry killed, while in the church itself men were killed or burned.

Aug. 4, 1666. Hurricane at Guadeloupe. A hurricane began at 6 P.M. and continued for twenty-four hours. Every vessel and boat on the coast of Guadeloupe was dashed to pieces, all the vessels in the Saints were driven on shore, and of Lord Willoughby's fleet of 17 sail with 2000 troops, only two were ever heard of afterwards. Houses and trees were blown down and a great number of cattle killed. The sea rose to an unusual height and flooded the land.

Aug. 4, 1829. Moray Floods. Heavy rain began to fall on the evening of Aug. 2 in the upper parts of the valleys of the rivers Nairn, Findhorn and Spey, and continued almost without interruption until the morning of Aug. 4. It came mainly with a north-east wind, with such volume and force that it penetrated all the doors and windows facing in that direction. No rain-gauges were in operation in the area of heaviest fall, but it is not unlikely that the amount which fell on Aug. 3 exceeded any falls which have been actually recorded in the British Isles. The Findhorn at its greatest height filled the valley, 200 yards wide, to a depth of 17 feet above the normal surface of the river, this level being marked by a tablet.

Aug. 5, 1783. Great Eruption of the Asama-yama (Japan).—The Asama-yama, one of the principal Japanese volcanoes, lies 90 miles north-west of Tokyo and rises to a height of 8136 feet above the sea. The great eruption of 1783 began on May 9 and lasted 88 days, culminating on Aug. 5, when a huge mass of molten lava and hot mud descended from the crater and covered an area 2 miles from the crater and 4 miles wide at the base to a mean depth of 100 feet. This lava did not reach the villages and caused no loss of life or property. It was followed, however, by a great avalanche of volcanic materials that swept down, at first with a velocity of more than 50 miles an hour, and caused enormous damage in all the villages along the northern base of the mountain. The river Azuma-gawa was blocked for a time, but the gathering waters broke through the dam and

swept away houses along a course of more than 50 miles. The number of lives lost by the avalanche and flood was 1162. The district covered by the ashes was about 4250 square miles and the total volume about one-sixth of a cubic mile.

Aug. 7-14, 1899. West Indian Hurricane.—A hurricane of exceptional violence struck the West Indies near Guadeloupe, crossed the Leeward and Virgin Islands, Porto Rico, and the Bahamas, and continued along the east coast of the United States. There was great destruction of life and property, especially in the island of Porto Rico, where more than 3000 lives were lost, mainly by drowning, and many more died afterwards from starvation. The coffee crop, worth more than £1,400,000, was almost completely destroyed. The storm was traced from America across the Atlantic into the Mediterranean, where it finally dissipated.

Aug. 8, 1924. Transport of Insects.—The Oxford University Expedition to Spitsbergen recorded that after several days of south-westerly winds, on the morning of Aug. 8, living hover-flies and aphides were observed in considerable numbers, crawling on the ice of the glaciers. These were collected and were afterwards shown to have been carried from the forest belt of northern Europe, a distance of at least 800 miles.

Aug. 9, 1911. Heat in London.—The summer of 1911 was noted for its great heat in England. On Aug. 9 the thermometer in the Glaisher stand at Greenwich registered exactly 100° F., the highest authentic shade temperature in Great Britain. The maximum was not momentary, but was maintained almost continuously from 3 to 3.30 P.M.

Societies and Academies.

PARIS.

Academy of Sciences, June 2.—**Mesnager**: The optical determination of internal strains in solids of three dimensions. Remarks on a communication by Henry Favre on the same subject.—**H. Deslandres**: Properties of the series and abnormal lines in atomic spectra.—**L. Blaringhem**: The heredity of sex in *Aquilegia vulgaris*.—**Louis Lapicque** was elected a member of the Section of Rural Economy in the place of the late L. Lindet.—**Gaston Julia**: Some harmonic majorants.—**Georges Bouligand**; Poles, essential singularities.—**Victor Vâlcovici**: A mixed problem.—**T. Bonneson**: Inequalities between arithmetical means.—**Léonidas Kantorovitch**: Functions of the (U) type.—**Luigi Fantappié**: The singularities of a linear analytic functional of a function of several variables.—**J. Haag**: The theory of the spiral.—**Jean Chazy**: The velocity of propagation of attraction.—**N. Stoyko**: The orbit of the trans-Neptunian star discovered at the Lowell Observatory.—**J. Le Roux**: The interpretation of Michelson's experiment.—**Edgar Baticle**: The problem of the wall supporting a mass of powder.—**Mlle. Simone Boudin**: Coloured crystalline stratifications. Study of *p*-toluidine, *β*-naphthylamine and diphenylamine. A modification of the technique proposed by René Marcelin for the study of the development of the elementary leaflet of *p*-toluidine, with application to other substances.—**R. Forrer**: A method of discussion of the magnetic moments of alloys, and the common measure of atomic moments.—**A. Dauvillier**: The realisation of integral microradiography. The radiography of microscopic objects has offered great experimental difficulties. The author uses plates similar to those devised by Lippmann for interferential photography, prepared with colloidal silver according to the technique described by Watteville. A reproduction of a radiograph, with a magnification of 600, is given.—**Mme. Pierre Curie and Mme. S. Cotelle**: The average life of ionium. The method used, based on the rate of formation of radium in a mixture of ionium and thorium oxides, assumes only a knowledge of the atomic weights of ionium, thorium, and of the ionium-thorium mixture utilised in the experiments. The value obtained, 119,000 years, is intermediate between that of Soddy (110,000 years) and that of St. Meyer (130,000 years).—**F. Joliot and Mme. Irène Curie**: The radiations associated with the emission of the α-rays of polonium.—**G. Reboul and G. Déchène**: The activation of matter by the brush discharge. The brush discharge, produced by e.m.f. of 20,000-100,000 volts, activates metallic plates, communicating an activity measurable by an electrometer, and persisting for up to 72 hours. The curve corresponds to the superposition of three superposed exponentials of periods of 3 minutes, 27 minutes, and 20 minutes. The residual activity has a period of 10·6 hours. From these measurements the activity produced would appear to be due to the disintegration of the emanations of radium and thorium.—**Louis D'Or**: The manometric and spectrographic study of the thermal dissociation of pyrites, FeS_2. The thermochemical equation of the decomposition is $2FeS_2 = 2FeS + S_2 - 61,000$ cal. The energy of fixing the first atom of sulphur is 90,500 cal., whilst that of the second is 82,500 cal.—**M. Bourguel and P. Daure**: Chemical constitution and the Raman effect: the acetylene linkage.—**Ch. Jovignot**: Method and testing apparatus giving the extension coefficient and the breaking load of metallurgical products in thin sheets.—**G. Dupont, J. Lévy, and J. Allard**: The mechanism of the action of catalysts in the autoxidation of abietic acid.—**Georges Darzens**: The transformation by isomerisation of benzylvalerolactone into tetrahydromethylnaphthalene carboxylic acid. This transformation is effected by heating to 120°-125° C. with 64·5 per cent sulphuric acid with constant agitation for eight days. The reaction is very slow, but, allowing for recovered lactone, quantitative.—**Félix François**: The action of selenoxanthydrol on *β*-diketones and on ethyl acetoacetate.—**Mlle. Marie Thérese François**: The neutralisation of castor oil. A suggestion for the use of commercial triethanolamine for the removal of acid from castor oils used for lubricating purposes.—**Paul Combes and Roger Campredon**: The study of a new deposit of calcite exposed during the excavations for the new entrance to the port of Saint-Nazaire.—**Jacques de Lapparent**: The amount of titanium in bauxites.—**L. Dollé**: The *marcas* of the high plateau of Artois.—**A. Guilliermond**: Homo- and heterothallism in the yeasts.—**André Dauphin**: The histological characters of roots developed separately.—**Philippe Fabre**: An electrical hæmodromograph.—**Gordon H. Scott**: The arrangement of the mineral constituents of the nucleus during mitosis.—**I. I. Nitzescu and I. D. Georgescu**: The amount of citric acid in some animal fluids (cephalo-rachidian fluid, aqueous humour, follicular liquid, amniotic fluid).

BRUSSELS.

Royal Academy of Belgium, Nov. 9.—**G. Cesàro**: Cells with minimum surface. A mathematical discussion on the form of cell made by the bee.—**Th. de Donder**: Affinity. (Part 2.) Discussion of open systems with osmotic pressure, surface tension, and adsorption.—**G. Balasse and Mlle. G. Galet**: Iodine spectra with weak excitation. The tubes giving the spectra were without electrodes and the oscillating current, of 70 metres wave-length, was maintained by two triode emission valves. Details are given of

the method of purifying the iodine. All probable impurities were sought for spectroscopically and proved absent.—**F. Corin**: Contribution to the study of the chloritoides. An application of the methods of Fedorow to the study of these minerals.—**Marcel V. L. Homès**: Observations on the structure and cell division of living *Halopteris filicina*.—**Lucien Godeaux**: (1) The Lie quadrics of certain surfaces.—(2) The Guichard transformation and certain quadrics considered by M. Demoulin.—(3) The united points of the cyclic involutions belonging to an algebraic surface.—**Yvonne Désirant**: Ethyl-difluoracetoacetate. Full details are given of the preparation, physical properties, and chemical reactions of the ester. The enol-ketone equilibrium was studied.—**Raymond Defay**: The thermodynamical study of surface tension. Affinity and adsorption velocity.

Dec. 7.—**Paul Stroobant**: Observations of the partial eclipse of the sun of Nov. 1, 1929. An account of results obtained at the Royal Observatory of Belgium (Uccle) and at the Astronomical Institute of the University of Brussels.—**Jean P. Bosquet**: Contribution to the invariantive theory of the calculus of variations.—**J. Jaumotte**: The movement of masses of air in the atmosphere.—**L.** and **M. Lapicque** and **Henri Fredericq**: Nerve and muscle chronaxies of the heart of *Limulus polyphemus*.—**Radu Badesco**: A functional equation.—**Maurice Lecat**: The application of azeotropism to functional chemical analysis. On the basis of extensive experimental work on the constant boiling mixtures formed by various classes of organic compounds, the author has devised a scheme for determining the class of an unknown organic compound from its azeotropic characters.—**R. H. J. Germay**: The application of a method of successive approximations to the solution of the Gauss equation $\sin(z-q) = m\sin^4 z$.

Jan. 4.—**Th. de Donder**: The photonic field.—**G. Cesàro**: The ellipse circumscribed round a triangle and having for its centre the centre of the inscribed circle.—**J. E. Verschaffelt**: Determinations of surface tension by measuring the force required to remove a flat disc.—**H. Buttgenbach**: The optical appearances of the cleavage plates of rhodonite.—**J. Melon**: The orientation of the optical ellipsoid of rhodonite.—**Raymond Defay**: The chemical kinetics of Th. de Donder and stable and metastable equilibria.—**Jacques van Mieghem**: Study of retarded potentials.—**G. van Lerberghe**: The calculation of the fugacities of a solution.—**Th. Lepage**: A characteristic property of the equations of the extremals of multiple integrals.

Feb. 1.—**F. Corin**: Contribution to the petrographical study of the lodes of the Bastogne region.—**M. Kraitchik**: The statistical study of prime numbers.—**Raymond Defay**: (1) The thermodynamical study of surface tension. Affinity and adsorption velocity.—(2) The chemical kinetics of Th. de Donder and stable and metastable equilibria.—**M. Cosijns** and **R. Moens**: A precision wavemeter. Details of a wavemeter capable of rapidly measuring frequencies between 3×10^4 and 3×10^8 with an accuracy of 0·001 per cent in absolute value.—**J. Jaumotte**: A movement quasi-equivalent to the movement of the atmosphere.

CRACOW.

Polish Academy of Science and Letters, Jan. 13.—**F. Leja**: The linear transformations of double and multiple series.—**Mlle. A. Dorabialska**: The heat yield of some radioactive minerals. Results of measurements with an adiabatic microcalorimeter of the heat in calories per hour per gram of uraninite, johannite, thorianite, Arendal orangite, thorite and monazite. Three minerals, orangite, thorite, and monazite, give a calorific effect much greater than that calculated from their chemical composition: this requires theoretical and experimental explanation.—**K. Dziewoński** and **J. Reiss**: The oxidation of acetyl-acenaphthene.—**F. Górski**: Increase of accuracy in the method of counting the bubbles in photosynthetic researches.—**E. Godlewski, jr.**, and **Mlle. I. Latinik**: The ontogenetic and regenerative growth of *Axolotl*.—**A. J. Klisiecki**: The movement and pressure of the blood in the arteries.

Feb. 10.—The Starunia rhinoceros. (1) **J. Nowak** and **E. Panow**: Geological characters. (2) **J. Tokarski**: The mineralogical characters of the diluvial mud. (3) **W. Szafer**: Character of the flora. (4) **J. Stach**: Description and reconstruction of the rhinoceros.—**T. Mazewski**: Some points of the theory of length.—**E. S. Pearson** and **J. Neyman**: The problem of two samples.—**C. Zakrzewski** and **T. Nayder**: The refraction of electric waves ($\lambda = 12$ cm.) in some electrolytes. No difference could be found between the index of refraction of water and those of the solutions of electrolytes used. The value found, 8·8, was identical within the limits of experimental error with the index found with long waves.—**M. Lancucki**: Sorption and chemical reactions in the atomic radius.—**Mlle. M. Moraczewska**: New absorption bands of selenium vapour in the extreme ultra-violet.—**M. Centnerszwer** and **W. Wittandt**: The velocity of solution of aluminium in alkaline solutions.—**K. Dziewoński**: The syntheses of ketones, derivatives of 1-benzylnaphthalene.—**M. Książkiewicz**: Geological researches in the Wadowice Carpathians. Stratigraphic and tectonic relations.—**J. Talko-Hryncewicz**: A contribution to the craniology of the present population and of past races of central Asia.—**J. Lenartowicz**: Researches on experimental syphilis.

VIENNA.

Academy of Sciences, May 2.—**W. Knapp**: The action of *o*-phthalylchloride on thio-phenol-methyl-ether.—**R. Fischer**: Testing with blood-gelatin for saponin in plants.—**M. Beier**: Zoological expedition to the Ionian Islands and the Peloponnesus (12). The ants of the Ionian Islands by **B. Finzi**.—**M. Radakovic**: Studies on the Raman effect (8). Calculation of simple molecular models. A system of particles bound together by elastic forces and an attempt to calculate the oscillations in a simple case.—**H. Winter**: The pole of inertia and its application in the graphic dynamics of plane gears.—**E. A. W. Schmidt** and **G. Stetter**: Ionisation of single α- and H-rays at the end of their range.—**E. A. W. Schmidt** and **G. Stetter**: Researches on α-reflection and disintegration effects with light elements.—**A. Dadieu** and **K. W. F. Kohlrausch**: Studies on the Raman effect (9). The Raman spectrum of organic substances. Molecules of different patterns were considered, $X-CH_3$ and $X-(CH_2-X$, as systems of so many points and so many degrees of freedom, with an internal oscillation of the H atom and an external oscillation of the X with regard to the methyl group. As special examples $ClCH_3$, Cl_2CH_2, Cl_3CH gave useful results.—**R. Springer** and **H. Roth**: A sort of turbulence-friction in binary mixtures of liquids.—**R. Kremann, B. Korth**, and **E. I. Schwarz**: Electrolysis of molten silver-lead alloys. With high current density a limiting value to the concentration of silver round the cathode was observed.—**R. Kremann** and **E. I. Schwarz**: The electrolysis of bronzes with added silver. Silver and copper concentrate at the cathode. The percentage enrichment of silver is less with increasing concentrations of silver.—**R. Kremann, F. Bauer, A. Vogriň**, and **H. Scheibel**: The change in direction of migration of alkali and other metals during the electrolysis of their

nalgams in relation to the concentration. There is transformation point above which Na, K, and Ba oncentrate at the cathode; Bi even from the lowest ercentages moves towards the anode. Apparently e polarity of the components of the alloy determines e direction of migration.—**R. Kremann** and **W. iwetz**: Electrolysis of bronzes with added lead. opper migrates to the cathode, lead to the anode. or high current density the enrichment of lead is ater in the alloys that are poorer in lead.—**F. Hölzl** nd **K. Rokitansky**: The mobilities of some ions conaining iron (2). The influence of radicle substitution the mobility of complex iron-ions. Comparisons ere made between $Fe(CN)_6$, $Fe(CN)_5CO$, $Fe(CN)_5NO_2$, nd other groups. From conductivity measurements ere calculated the radii corresponding to the apparent mic volumes. The substitution of CO for one CN ade little difference. By contrast $Fe_4(NO)_7S_3$ has a ery small mobility.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, Vol. 16, No. 3, ar. 15).—**Albert F. Blakeslee** and **Ralph E. Cleland**: ircle formation in *Datura* and *Œnothera*. The view adopted that segmental interchange is a possible asis of circle formation of the chromosomes of those enera.—**Ralph E. Cleland** and **Albert F. Blakeslee**: nteraction between complexes as evidence for segental interchange in *Œnothera*. The segmental nterchange hypothesis leads to useful predictions chromosome configuration in certain complexombinations.—**J. T. Buchholz** and **A. F. Blakeslee**: en-tube growth of the primary mutant of *Datura*, olled, and its two secondaries. **R. B. Lindsay** and **J. Seeger**: Operational calculus in quantum meanics. Some critical comments and the solution of pecial problems.—**H. Bateman**: Physical problems ith discontinuous initial conditions.—**F. Zwicky**: the possible influence of the mosaic structure crystals on the determination of Avogadro's umber. There is a discrepancy between the wavength of X-rays as determined by the method reflection from a ruled grating and by reflection om a crystal of known structure, the latter of hich involves use of the density and Avogadro's umber. The conception of mosaic structure leads a correction to this method, bringing the two results to better agreement.—**Everett S. Wallis**: The oblem of preparing optically active free radicals.—**aymond F. Blount**: The implantation of additional pophyseal rudiments in urodele embryos. Where ecal endoderm only was transplanted, the results re negative. When grafts including ectoderm and derlying neural tube were used, pigmentation was creased and body length was decreased while certain rts showed disproportionate growth and there was rly sexual maturity.—**Andrew Watson Sellards**: he cultivation of treponemata from the blood of rmal monkeys (*Macacus rhesus*) and from the blood monkeys infected with yellow fever. Repeated noculations with culture from yellow fever animals used death, but the liver lesions were not always ose occurring in yellow fever. Thorough immunisan with culture of treponemata from yellow fever urces produced partial to complete protection ainst yellow fever virus.—**Marston Morse**: The oblems of Lagrange and Mayer under general end nditions.—**R. L. Wilder**: Concerning perfect conuous curves.—**M. H. A. Newman**: Combinatory ology of convex regions.—**Tibor Radó**: Some rerks on the problem of Plateau.—**Eldred Currier**: problem of the calculus of variations in *m*-space h end-points variable on two manifolds.—**Willem uyten**: (1) On some statistical properties of double stars in space. (1) A formula for the estimation of the period in a relatively fixed system. The formula allows of the calculation of the period of a binary system from the angular separation, the parallax and the luminosity, the chance being 2 out of 3 that the actual period is between 0·4 and 2·5 times the computed value.—(2) On the mean period of double stars in space. Computed values agree well with those known and the equation is applied to all double stars nearer than 10 parsecs. The general conclusion is that the median-mean period is about 300 years and half of the binaries in space probably have periods between 20 and 4000 years.

SATURDAY, AUGUST 2, TO *TUESDAY*, AUGUST 12.

INSTITUTION OF ELECTRICAL ENGINEERS (London Students' Section).—Summer Meeting in the Ruhr area and Switzerland.

CONGRESSES.

AUGUST 3 TO 9.

INTERNATIONAL CONGRESS FOR SEX RESEARCH (at House of British Medical Association).

Monday, Aug. 4.—Prof. F. A. E. Crew: Puberty and Maturity (Address). Papers relating to Puberty and Maturity.

Tuesday, Aug. 5.—Papers on the Biology of Testicular and Ovarian Function.

Wednesday, Aug. 6.—Papers on Hormone Therapy.

Thursday, Aug. 7.—Discussion on Psychology and Biology.

Friday, Aug. 8.—Papers on the Biological and Therapeutical Aspects of Control of Human Fertility.

Among the papers to be communicated to the Sectional Meetings are The Aschheim-Zondek Test for Pregnancy (Prof. Aschheim); The Corpus Luteum Hormone (Dr. Clauberg); Biological Tests of the Female Hormone (Menformone) (Assistants from Prof. Laqueur's Institute); The Channels and Significance of Excretion of the Female Sex Hormone (Prof. R. T. Frank); The Male Sex Hormone (Prof. S. Loewe); Evidence for the Metabolic Basis of Sexuality (Dr. O. Riddle); Human Hybrids (Prof. C. G. Seligman).

AUGUST 4 TO 9.

INTERNATIONAL CONGRESS OF EXPERIMENTAL CYTOLOGY (in conjunction with the Anatomical Congress) (at Amsterdam).

AUGUST 4 TO 9.

INTERNATIONAL VETERINARY CONGRESS (in Central Hall, Westminster).—Discussions on Foot-and-Mouth Disease, Tuberculosis, Infectious Abortion, The Relationship of the Veterinary Surgeon to Animal Husbandry, Veterinary Science in Relation to Public Health, and The Law Governing the Practice of Veterinary Medicine and Surgery. Sectional Meetings on Variola in Domestic Animals, The Use of Drugs in the Treatment of Diseases caused by Worms, Theileriases, Fowl Typhoid and Bacillary White Diarrhœa, Anthrax, Swine Fever, Milk Fever, Fowl-pox, Genetics, Rabies, Standardisation of Biological Products, Acute Infectious Mastitis, Control of Trypanosomiases, Deficiency Diseases, Black-leg, Scientific Feeding of Animals, Distemper, Bovine Sterility, Rinderpest, Treatment of Parasitic Diseases, Diseases of the New-born, and Fowl Plague.

AUGUST 5 TO 7.

IMPERIAL HORTICULTURAL CONFERENCE (to discuss the best methods of approach to horticultural problems and the technique involved) (at Royal Society of Arts).

Tuesday, Aug. 5, at 10 A.M.—Sir Robert Greig: Bureaux and their Work. The Director and Chief Officer of the Bureau: Discussion of the Work of the Imperial Bureau of Fruit Production and Future Lines of Development. This will be prefaced by a précis of the work already done.

At 11.30 A.M.—F. L. McDougall: Possible Development of Fruit Growing in the Empire from an Economic Point of View.

At 12.15.—J. L. Brown: The Evolution of the New Zealand Fruit Board.

Experiences of Horticultural Research—

At 2.30.—Dr. W. T. Macoun: In Canada:—(*a*) Centralised.

E. F. Palmer: (*b*) At an Unattached Station.

At 3.10.—Prof. A. C. D. Rivett: In Australia.

At 3.30.—Dr. B. Hahne: Horticultural Research in the Union of South Africa.

At 3.40.—W. G. Freeman: Tropical and Sub-tropical Fruit Industry. Difficulties Encountered and Lines of Attack.

At 4.15.—Sir Frederick Keeble: An Industrial Research Station.

Wednesday, Aug. 6, at 10 A.M.—Sir Daniel Hall: The Directions in which Experimentation is likely to be Valuable in Horticulture.

Field Experiments:—

At 10.45 A.M.—T. N. Hoblyn: The Adaptation of Modern Statistical Methods to Horticultural Conditions.

At 11.30 A.M.—Prof. E. E. Cheesman: Practicability of the Application of Statistical Method in the Case of Tropical and Sub-tropical and other Crops.

At 12.15.—F. J. Martin: Field Experiments in certain Tropical and Sub-tropical Crops in West Africa.

Application of Pure Sciences to Horticultural Problems under—Temperate Conditions:—

At 2.30.—Prof. B. T. P. Barker: Fruit Products and Associated Problems.

At 3.—Prof. V. H. Blackman: Some Physiological Considerations in Horticulture.

Tropical and Sub-tropical Conditions:—

At 3.30.—Dr. E. J. Maskell and Dr. T. G. Mason: Physiological Work in the Tropics. Some of the Problems with special reference to Cocoa, and some Possible Lines of Attack.

Soil and Climate Survey as a Basis for Fruit Research:—

At 4.—T. Wallace: Soil and Climate Survey as a Basis for Fruit Research.

T. Rigg: Soil Type and Manuring in Relation to Yield and Quality of Nelson Apples.

A. J. Prescott: Soil and Survey Work as a Basis for Fruit Production in Irrigated Areas.

At 4.30.—H. V. Taylor: Meteorology and Fruit Production: The British Scheme of Research.

Thursday, Aug. 7.—Progress of Fruit Storage Methods:—

At 9.30 A.M.—Dr. F. Kidd: A Survey of the Principal Fruit Storage and Transport Problems of the Empire to-day.

At 9.50 A.M.—T. Wallace: Factors influencing Storage Qualities of Fruits.

At 10.10 A.M.—Dr. A. J. Smith: Problems of Biological Engineering in the Cold Storage of Fruit.

At 10.30 A.M.—Dr. A. Horne: The Infection and Invasion of the Apple Fruit by Fungi in Relation to the Problem of Storage.

At 10.50 A.M.—Dr. D. Haynes: Chemical Change in Stored Apples: The Relation of the Time of Picking to the Chemical Composition and Storage-life of the Apple.

At 11.10 A.M.—Dr. L. P. McGuire and Dr. C. W. Wardlaw: Investigations of the Storage Behaviour of Bananas at the Low Temperature Station of the Imperial College of Tropical Agriculture, Trinidad.

At 11.30 A.M.—W. T. Hunter: Recent Progress in the Study of Johnathan Breakdown in U.S.A. and Canada.

At 11.50 A.M.—R. G. Tomkins: Biological Effects of Atmospheric Humidity.

At 12.10.—Meirion Thomas: Biochemical Study of Functional Diseases in Fruits.

Dr. B. T. Dickson and W. M. Carne: The Present Position of the Bitter Pit Problem in Australia.

R. Wheeler: Fruit Transport Problems in Canada.

E. A. Griffiths: Problems of Storage and Transport.

Prof. J. Young: Citrus Storage Investigations in Australia.

At 12.30.—F. A. Stockdale: Sources and Training of Future Horticultural Research Workers.

AUGUST 7 TO 15.

INTERNATIONAL HORTICULTURAL CONGRESS (in London).—*Papers to be read on Aug.* 8, 11, *and* 13:—

Prof. Priestley: Vegetative Reproduction from the Standpoint of Plant Anatomy.

Dr. Van der Lek: Anatomical Structure of Woody Plants in Relation to Vegetative Propagation.

Dr. R. Salaman: Vegetative Mutations.

Prof. E. Baur: Production of Mutations by External Stimulus.

Dr. F. E. Denny: The Excitation of Dormant Buds under External Influence.

John Innes Horticultural Institution: Graft Hybrids.

John Innes Horticultural Institution: Vegetative Production of Polyploids.

John Innes Horticultural Institution: Sterility.

G. E. Yerkes: Raising Root Stocks from Seed.

Dr. C. G. Dahl: Root Stocks from Seeds of known Parents.

Dr. R. J. D. Graham and L. B. Stewart: Special Methods of Practical Utility in the Vegetative Propagation of Plants.

Miss Mary E. Reid: The Influence of the Nutrient Conditions of Seeds and Cuttings upon the Development of Roots.

Prof. P. W. Zimmerman: Factors influencing Root Growth of Cuttings.

Dr. A. B. Stout: The Inter-relations between Vegetative Propagation and Seed Reproduction.

N. Esbjerg: Varieties grown on own Roots.

Prof. N. I. Vavilov: The Wild Progenitors of Fruit Trees in Turkestan and in the Caucasus.

R. G. Hatton: The Development of a Research Programme around the 'Build Up' of a Fruit Plant.

Dr. H. Faes: Vine Propagation.

L. Ravaz: The Influence of American Stock on French Vines.

W. G. Freeman: Vegetative Propagation of Cacao and the West Indies Citrus.

Prof. T. Tanaka and Y. Tanaka: Propagation of Citrus Fruits in Japan.

Prof. H. J. Webber: Studies on Rootstock Reactions in Citrus.

Dr. F. F. Halma: The Propagation of Citrus by Cuttings.

Dr. H. P. Traub: The Ripening Process in Fruits, with special reference to the Fig and the Grapefruit.

Prof. B. T. P. Barker: The Fruit Tree Complex in Relation to Environment: Some current Investigations at Long Ashton.

Prof. N. E. Hansen: Fruit Stocks where Mercury Freezes.

Prof. E. C. Auchter: American Experiments in Propagating Deciduous Fruit Trees by Stem and Root Cuttings.

W. T. Macoun: National Tastes in Apples.

Dr. L. Filewicz: The Frost Injuries of Fruit Trees in Poland in 1928-29, with special reference to the Influence of the Stock and Scion upon the Resistance of the Apple-trees against the Frost.

Dr. P. J. S. Cramer: Rubber Budding.

W. A. Orton: Propagation in Tropical Countries.

Prof. P. Work: Some Scientific Problems in connexion with Vegetable Seeds.

Eng. G. Jacobsen: Electric Heating of Soil in Hotbeds and Hot houses.

Prof. B. Fedtschenko: The Horticultural Work of Russian Botanical Gardens.

Prof. C. Regel: The Botanical Garden of the Present Day.

H. J. Rumsey: Horticultural Progress in Australia.

SATURDAY, AUGUST 9, 1930.

Science and Food Supply.

IN a celebrated address to the British Association in 1898, Sir William Crookes, discussing what he called the "Wheat Problem", predicted a world shortage of 17 million bushels of wheat in 1931, and went on to assert: "it is the chemist who must come to the rescue of the threatened communities. It is through the laboratory that starvation may ultimately be turned into plenty." The warning was dramatic, and created something of a sensation at the time. The anxiety, it is true, was not shared by such agricultural authorities as Sir John Bennett Lawes and Sir J. Henry Gilbert, but they would have been the first to endorse all that Sir William Crookes said about the importance of the scientific worker in securing the maximum return in agriculture.

This historic address was mentioned by Dr. Levinstein in his recent presidential address to the Society of Chemical Industry. Dr. Levinstein pointed out that if a shortage of wheat is unlikely in 1931 it will be due, not to better fertilising and increased yields per acre, but to a larger acreage under cultivation. The enormous production of nitrogenous fertilisers during the last thirty years has had little effect upon the wheat supplies, and has gone instead to produce sugar, potatoes, rice, and other commodities. The difficulty has been met by extending the zone within which wheat can be profitably cultivated. This has been done partly by the development of new varieties of wheat better adapted to difficult conditions than those previously known, partly by the better utilisation of moisture reaching the soil, and partly also by improved agricultural implements. Thus not only the chemist but also the biologist and botanist, the soil-physicist and the agricultural engineer, have played their part in averting the food shortage which Sir William Crookes believed to be impending.

In this period agricultural chemists have produced no spectacular successes like those obtained with artificial fertilisers in the middle of the nineteenth century. The new methods of crop production have been made possible by an immense amount of scientific research, the practical importance of which was often not apparent at the time. For this reason, although agricultural science stands in higher repute with farmers than ever before, the contribution which science has made towards the improvement of agriculture is far from being appreciated by the community. Lord Melchett was undoubtedly right when he asserted recently that the importance of the chemist as a prime con-

tributor to the progress of civilisation is not yet realised, and this is notably true in the matter of food supply.

Even those who are aware of the part the chemist has played in developing the supply of artificial fertilisers by the fixation of atmospheric nitrogen, for example, or of his work as an analyst in detecting and preventing adulteration and in securing the purity of all kinds of foodstuffs, are unaware of the contribution of the biochemist and the important results of his study of the soil bacteria. In recent years the contribution of the chemist in the sphere of insecticides and fungicides has become as important as in the provision of fertilisers. At the last Imperial Agricultural Research Conference the need for a greatly extended chemical investigation of possible insecticides and fungicides for the control of diseases and pests was realised, and a resolution of the Conference recommended that an investigation of the whole chemical field should be undertaken by chemists working in collaboration with entomologists and plant pathologists. With the growth of intensive cultivation the control of plant pests assumes great importance, and the continuance of civilisation's power to feed the growing population of the world is largely dependent on the ability of the chemist and his fellow workers to protect our crops from such pests.

In a country such as Great Britain the adequacy of a food supply involves not only questions of production and protection of foodstuffs, but also their storage and transport, often for considerable periods. For the past ten years the Department of Scientific and Industrial Research has directed a number of investigations into the changes which occur in foodstuffs during cold storage. These investigations have already been of practical value in improving conditions of transport and storage of fruit and in checking wastage during long voyages from overseas. Success in the storage of fruit is now known to depend upon a close knowledge of chemical changes which follow severance from the tree and the effect upon them of temperature, humidity, age when gathered, soil, climate, etc. A relationship has been established between the chemical composition of an apple and its susceptibility to disease, and the first step has thereby been taken towards enabling the grower to control soil conditions so that the fruit possesses both better storage properties and greater resistance to disease.

Similarly, investigations at the Low Temperature Research Station at Cambridge have upset the accepted view that chemical reaction in tissues is almost completely inhibited in freezing and indicated the existence of a definite temperature zone within which the living muscle may be frozen and revert to its original condition on thawing. Other work on the conditioning of meat has indicated that the prejudice against frozen beef may be due to the use of inferior beef rather than to the effects of freezing, and researches carried out at sea in special trawlers have demonstrated the possibility of so improving the handling and transport of white fish that a higher proportion of the total catch can be handled in a 'fresh' and marketable condition after 10-11 days storage than was possible after 6-7 days by the old methods.

In such investigations not only the chemist but also other scientific workers have played their part. The majority of important advances in applied science under modern industry are the result of team work in which all kinds of scientific workers have co-operated, and equally with the chemist other classes of scientific workers are overlooked by the community. Thus scientific workers have already quietly averted a world shortage of foodstuffs which appeared to threaten us a generation ago. Until, however, the importance of their contributions are fully realised, the business or government of a country is unlikely to take the long range or scientific views of agricultural policy which Dr. Levinstein outlined.

For this position scientific workers are themselves at least in part to blame. With a wealth of material at their disposal—to take the report of the Empire Marketing Board as one example—they have done little to educate the community as to the contribution that science makes to the food supplies of the world, or to remove some of the pressing problems of food production out of the arena of political prejudices and debate into an atmosphere of impartial and scientific examination. Scientific workers must assume to a much greater extent the responsibility of leadership which their knowledge thrusts upon them, if mistakes of policy are to be avoided which prejudice the well-being of future generations. While there may be different opinions as to the precise manner in which science should exert a full and right influence on public affairs, there is little doubt that the recently revived Parliamentary Science Committee offers a valuable line of advance. Support of that Committee may not only provide a form for the expression of scientific opinion upon public affairs, but may also promote the participation of men of science in public life and their representation in Parliament, and even lead to the creation of the Ministry of Science which we have often advocated.

Natural History of New England.

The Boston Society of Natural History, 1830–1930. Edited by Capt. Percy R. Creed. Pp. xii + 117. (Boston, Mass.: Printed for the Society, 1930.)

FEW societies of natural history can boast such a fine record of achievement both in the encouragement of research and in public education as that of Boston, which recently has celebrated its hundredth anniversary. Boston in 1830 was the centre of a populous seaboard, through which most of the foreign commerce entered the United States, while it possessed a large fleet of clippers, merchantmen, and whalers. The land behind was settled by an industrious population, who feared only God and the devil. The Almighty gave such animals and plants as were beneficial, while Satan was responsible for the rest, about which it were safest to be incurious. The farmer's existence was unspeakably hard and his amusements were few. In the ports, however, there was great interest as to foreign lands, and skippers took a pride in bringing curios to deck such local museums as that of New Salem. The museum 'instinct' thus started began to spread to Nature in the country behind them, from which the Indians had already disappeared, but ideas were chaotic.

It was in these circumstances that about twenty Boston men banded themselves together to found their Society of Natural History. They included no one who even knew the birds, fishes, or mammals of their neighbourhood. The public was indifferent to their aims and regarded them as 'busy triflers'. There was no museum that could help them. Yet they dared to get themselves incorporated by the Commonwealth of Massachusetts, thereby undertaking the responsibilities of a national institution. They appointed fifteen office-bearers, including eight 'curators' whose duty was to collect the animals and plants of New England. They induced the legislature to appoint six persons to survey the natural history of the home State, these working largely under their advice. A small legacy overcame many difficulties and enabled their first hall to be acquired in 1848. Here they developed their collections, while they gave the only instruction in biology in Boston. The Society claimed with Louis Agassiz that the study of Nature should be made "an indispensable part of all education", and its classes were expressly designed to help teachers to acquire the necessary knowledge. In 1861 the Commonwealth recognised its position and gave a noble site in the 'west end' of Boston, whereon was erected a museum and library of natural history. In 1834 publication of the *Boston Journal of Natural History* was started, and this has been added to by Proceedings, Memoirs, and Bulletins, the contributors to which have comprised many of the best-known naturalists in America. These were used largely for exchange purposes, and the result is a library of 100,000 catalogue entries, nearly complete in all that concerns North America.

In 1871 practical steps were taken to develop New England collections of rocks, plants, and animals, all to be arranged on the logical background of relationship. Later, with the foundation and development of the Harvard University collections in the Agassiz Museum, these were further developed, and afterwards the two museums made such an exchange that the local collections became concentrated in Boston and the exotic in Cambridge. Thus the two museums, the world institution of Harvard and that of the local society of New England, have come to bear a peculiar relationship to one another, the authorities of one being equally interested in the other. Pupils from the State schools visit one and demand to be taken to the other. They do not understand what they see, but they have an insatiable curiosity to see—and one visit is not enough. Sunday afternoons with their 2000 visitors to these museums is interesting, the present writer having once been requested to explain exhibits to a group of about twenty who had motored in thirty miles with the thermometer below 0° F. expressly for this visit.

To mention the names of the more distinguished naturalists of the Boston Society of Natural History would recall the story of the development of natural history in America, since Boston is its true metropolis of this study. Amongst the foundation members are found Amos Binney and A. A. Gould, leading conchologists of their day. The former gave his collection of plants, and later were added the John A. Lowell flowering plants with other collections of lichens and algæ, these having the sympathetic interest of Asa Gray. To Jeffries Wyman and F. W. Putnam were owed the genesis of a fine fish collection, the basis of Humphreys Storer's "Fishes of Massachusetts", 1867. Marine invertebrates were largely given by the elder and younger Agassiz, but this section looks for a great development in the new museum that is now imperatively necessary. Dr. Thaddeus W. Harris gave lectures in 1831, preaching the need of a proper study of insects in connexion

with agriculture. In 1841 he published "The Insects of Massachusetts injurious to Vegetation", which passed through several editions. His collection of insects, made a hundred years ago, is the oldest general collection in North America, and his 4700 species comprise about half the present known species of New England. The fossils are not spectacular save for reptilian footprints. They are mostly primary invertebrates, especially trilobites and brachiopods. Mammals, birds, and reptiles are the work of many hands, but Barbour and Allen may be trusted to have made their groups as complete as they well can be.

John James Audubon was a visitor to the Society in 1832–33 when preparing his superb "Birds of America", and the great Humboldt was a close correspondent, as might be expected, since it was his financial loan that enabled Louis Agassiz to become a biologist. Amongst the active workers, sympathisers, and helpers we find the names of practically every one of the older families of New England. There are, too, noble eulogies of their fellow-members, who devoted their lives to the natural history of their State, by Longfellow, Oliver Wendell Holmes, and James Russell Lowell, men distinguished by their art and ennobled by that love of natural history which they deemed to be a vital factor in the programme of all well-educated persons.

J. STANLEY GARDINER.

The Expansion of Consciousness.

The Ascent of Humanity: an Essay on the Evolution of Civilization from Group Consciousness through Individuality to Super-Consciousness. By Gerald Heard. Pp. xiv + 332. (London: Jonathan Cape, Ltd., 1929.) 15*s*. net.

THIS remarkable book will attract deep, if not wide, attention for several reasons. In the first place, it gives an entirely new setting to the doctrine of progress which was generally believed in the last century and has lately fallen into temporary disrepute; the author moves the centre of discussion from the external and mechanically organised world into the evolution of man's spirit itself. Secondly, it appeals strongly, and, as we think, too exclusively, to the psychological interest of the present day; it attempts a psychological explanation of some of the greatest movements and most famous characters in history, and this, even when not convincing, is always interesting and suggestive. Thirdly, it fits in admirably with the growing interest in world organisations and especially with the ideas underlying the League of Nations. It is a striking proof of the strictly scientific, or at least theoretical, point of view of the author that such obvious applications of his theory are not even mentioned. It would have made the book easier to read and attracted a wider public had he allowed himself more popular and topical illustrations of this kind.

The general thesis, however, though difficult and at times doubtful in its development, may be quite shortly and simply stated: "Man's consciousness was once pre-individual, a group-consciousness; it is now individual and is becoming super-individual." Combining this main doctrine with the 'spiral' idea of human progress, Mr. Heard has many brilliant *aperçus* in his review of anthropology. As we advance in a spiral up the steep ascent, we are able at certain points to stand over our primitive ancestors, and, looking straight down upon them, understand them better than intermediate generations have done, who went off in another direction. This, in fact, is the main argument, or at least suggestion, in Mr. Heard's interpretation of the primitive mind. The individualist psychologist of the eighteenth and nineteenth centuries went astray in studying early man by treating him as a small and undeveloped example of the same sort of mind as he had himself. We now, gradually acquiring, at a higher level, a 'co-conscious' mind, more similar in that respect to his own, can understand him better.

It will be clear from this—a typical and frequently repeated argument in the book—that Mr. Heard makes no pretence to a final or comprehensive judgment on any of the questions he discusses; he is, on the contrary, extremely modest and tentative throughout. But the issues involved are of such supreme moment, and his goal and the spirit in which he approaches it are so fine, that his book deserves careful reading and the criticism for which he pleads. "All efforts to interpret human events in economic terms have failed to produce a philosophy of history. The real advance, consistent but elaborate and concealed, is in man's spirit." With that general doctrine we may heartily agree.

One or two criticisms may be added, such as the author desires. His matter is much more complete on the psychological and anthropological side than on that of history or the philosophy of history. He has thought deeply and read widely on psychic questions and primitive psychology, but, when he comes to a review of theories about progress and the evolution of civilisations, Vico, Flinders Petrie, Spengler, and Henry Adams are the only authors he

names. To mention only one omission, he would have found in Comte's philosophy of history much that fits in and fortifies his own. To Comte also the present age is *par excellence* that of revolution, and this revolutionism is due to the bursting out of a growth of 'individuals' who have not yet learnt to subordinate their selfishness to the new form of co-consciousness on which both Mr. Heard and Comte substantially agree. For what else is the new super-consciousness except the sense of a common humanity of which we are all, individuals and nations, only subordinate and inseparable organs?

On one other point, a question of substance and vital moment, many readers will feel that Mr. Heard does not do justice to the 'individualism' which must pass away, if society is to advance. This cannot be regarded as a wholly evil thing. Not only was it the necessary condition of rising to a higher plane at all, but also it must be fulfilled and sublimated by the higher consciousness and not abolished. If the humanity of the future were to consist of a species of higher ants, acting only through the group-instinct, however large the group may be, all the most valuable achievements of the intermediate stage would have been lost. No doubt Mr. Heard would accept this amendment of his general argument; to work it out in detail and in practice is the supreme moral task of the future. "Self-knowledge is self-creation"—one of the best of his many good sayings—conveys his consciousness of it and his idea of the right line of approach.

F. S. MARVIN.

A Source Book in Mathematics.

A Source Book in Mathematics. By Prof. David Eugene Smith. (Source Books in the History of the Sciences, Vol. 2.) Pp. xvii + 701 + 8 plates. (New York: McGraw-Hill Book Co., Inc.; London: McGraw Hill Publishing Co., Ltd., 1929.) 25*s*. net.

THIS is a very entertaining volume, a surprisingly successful attempt to do what nearly all good judges would have declared to be impossible. Its aim is "to present the most significant passages from the works of the most important contributors" to mathematics "during the last three or four centuries".

It is easy to think of a dozen excellent reasons why such an attempt is sure to be a failure. Any compilation of this kind is bound to be scrappy, and in many ways unrepresentative, and no two competent mathematicians will ever be found to agree on principles of selection. The original presentation of an important idea is usually by no means the best, either logically or for purposes of instruction. The passages selected must be translated (if the book is to sell in the United States), and, however competent the translators, a great deal of the savour of the originals must be lost in translation. In short, it is very difficult to imagine any class of students or teachers to whom the book can possibly appeal except as a curiosity, and the time and money spent on its production might be used much more profitably in other ways.

The fact remains that Prof. Smith's volume is a very definite success; it is interesting to read and pleasant to possess. The translations are accurate and vigorous, the printing and illustrations excellent, and the general level of scholarship shown by the contributors is very much higher than is usual in scientific compilations. Among them are prominent researching mathematicians such as Bateman, Bell, and Tamarkin, as well as historians like Archibald, Cajori, and Smith; and Prof. Smith, as editor, has combined the activities of his collaborators with quite remarkable skill.

It is interesting to see what mathematician scores most freely, and no one will be surprised to find that it is Gauss. Gauss has five contributions; on congruences, on the law of quadratic reciprocity, on the fundamental theorem of algebra, on regular polygons, and on the conformal mapping of surfaces. Three of these at least would probably have been unanimous selections of any editorial board. Fermat also scores five, but one is merely the famous 'marginal comment' concerning the impossibility of $x^n + y^n = z^n$; Abel and Euler each score three. There is little Newton; but the volume is limited to pure mathematics. It is surely a mistake to have omitted Cantor and Weierstrass entirely, and Riemann is represented only on the geometrical side. I should have preferred to go without Horner's method or nomography, but I can see that a great many people would disagree with me. On the other hand, I was particularly pleased to find Tchebichef's work on primes, and the early writings on non-Euclidean geometry are particularly well represented.

I may conclude by mentioning a few historical curiosities chosen at random. The first use of π occurs in "Synopsis Palmariorum Matheseos: or, a New Introduction to the Mathematics" (1706), by William Jones, who seems to have been quite a good mathematician (p. 346). The addition formulæ for the sine and cosine seem to be due to Dithmarsus and Clavius (Christopher Clavius, "Astrolabium", 1593);

Clavius's 'method of prosthaphæresis' is almost an anticipation of calculation by logarithms (p. 459). Continued fractions are first found in Bombelli's "L' Algebra parte maggiore dell' aritmetica divisa in tre libri" (1572, p. 80); Cataldi (1613) gives what is practically the usual symbolism. G. H. Hardy.

Welsh Folk-lore.

Welsh Folk-lore and Folk-Custom. By Prof. T. Gwynn Jones. Pp. xx + 255. (London: Methuen and Co., Ltd., 1930.) 7s. 6d. net.

PROF. GWYNN JONES'S little book on Welsh folk-lore is a welcome companion and supplement to Miss Hull's "Folk-lore of the British Isles" in the same series. The author is able to deal in greater detail with topics on which Miss Hull could do little more than touch in covering the larger area. Here we have presented within a relatively small compass a much fuller statement of the chief features of the lore and custom of the Welsh people.

The composite character of English folk-lore and custom has often been pointed out. The same character is to be attributed to Welsh folk-lore in even a greater degree, where indeed it would seem probable that more of the earlier phases of primitive custom and belief have survived. This, perhaps, might have been expected from the cultural history of the principality. Settlers seem to have absorbed the tradition and culture of the earlier population to a greater degree than in England. It will be remembered that Giraldus Cambrensis noted this as characterising Norman invaders in Ireland, who became "Hiberniores ipsis Hibernicis".

The survival of very early tradition is exemplified in the stories of the Mabinogion, in which elements of a most primitive character are to be found side by side with features characteristic of the chivalrous civilisation of Norman times. Fairies and giants both figure prominently. As the late Sir John Rhys pointed out, the former are often of a pre-iron or even pre-metal age, as for example in the stories of the fairy-wife who vanishes on being struck accidentally by iron.

Prof. Gwynn Jones has devoted himself in the main to a record of fact; theories as to origins and parallels are mostly avoided. This is no doubt wise in view of the importance of securing a record of facts as extended as possible before they vanish entirely. But in a few cases a consideration of parallels found elsewhere would be of assistance to the reader who is not a specialist. As an example, the *Mari Lwyd*, the custom that at certain times a person known as *Mari* should carry round a horse's skull, should be compared with the similar traditional practice in the Isle of Man and at Ramsgate. It is suggested here that the custom may be connected with marriage; but more probably it is a general fertility rite which has been adapted to special occasions and seasons.

Among the many other topics with which the author deals, attention may be directed to the valuable account of holy and wishing wells. The book is a record of great value which, it may be hoped, will stimulate others to add to the material before it is too late.

Our Bookshelf.

Organic Syntheses: an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Editorial Board: Hans T. Clarke, Editor-in-Chief; Roger Adams, James B. Conant, Henry Gilman, C. S. Marvel, C. R. Noller, Frank C. Whitmore, C. F. H. Allen. Vol. 10. Pp. vii + 119. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1930.) 8s. 6d. net.

Among the more familiar of the thirty-one preparations contained in this volume are benzenesulphonic chloride, benzophenoneoxime, methyl oxalate, and anhydrous oxalic acid. Useful practical details will be found under all these headings: thus, benzophenoneoxime is gradually converted into a mixture of benzophenone and nitric acid when kept under ordinary conditions, and a method of inhibiting this decomposition is given. The less common preparations include durene, duroquinone, and pyromellitic acid. The last-named compound is made by oxidising finely powdered pine or spruce charcoal with sulphuric acid in presence of a little mercury, and it is remarkable that ordinary willow charcoal failed to yield this benzene derivative when treated in a similar way. A useful apparatus for the application of superheated alcohols in the formation of various high-boiling ethyl and methyl esters is described under the heading of ethyl fumarate.

Of biochemical interest are the preparations of casein (from milk), *l*-tryptophane and *l*-tyrosine (from casein), taurine (from ethylene dibromide through sodium 2-bromoethanesulphonate), erucic acid (from rape seed oil), and lauryl alcohol (from cocoanut oil). There is also a noteworthy series of preparations departing from acetone and proceeding through bromoacetone and acetol to *l*-propylene glycol; the latter process affords an example of the biological method of asymmetric reduction by means of yeast reductase. An appendix contains later references to preparations in preceding volumes, but the index covers the current volume only. A revised collection of the contents of the first nine volumes is to be issued in due course. J. R.

American Geographical Society. Special Publication No. 11: *Brief History of Polar Exploration since the Introduction of Flying.* By W. L. G. Joerg. To accompany a Physical Map of the Arctic and a Bathymetric Map of the Antarctic. Pp. v + 50 + 2 maps. (New York: American Geographical Society, 1930.) 5 dollars.

BOTH these are layer coloured bathymetrical maps on a scale of 1 : 20,000,000. The Arctic map is a revised version with insets and names in English of the map in Andree's "Handatlas" (1924). It is an excellent map with much detail. A slight misuse is made of the name Svalbard. It is the name for all the islands, except Jan Mayen, under Norwegian sovereignty in the Arctic Sea and not a synonym for the island of Spitsbergen itself.

The Antarctic map is new and gives a new version of the bathymetry of the Southern Ocean, though Mr. Joerg avoids that name. We note that the soundings of the *Discovery* between Tristan da Cunha and South Georgia do not seem to be included and of course those of the *Discovery* in her present expedition were not available. It was perhaps a pity to bring out a new map of the Antarctic at a time when several expeditions are at work in the south. A delay of a few months would have allowed the addition of the important discoveries of Sir Douglas Mawson in the *Discovery* and Capt. Riiser Larsen in the *Norvegia* in the region of Kemp, Enderby, and Coats Land. The American work in the Ross Sea region is shown.

It is to be hoped that the omnibus name of Antarctic Archipelago for all the islands between Clarence Island and Charcot Island will be abandoned. It is neither explicit nor necessary. The practice of British cartographers of using Coats Land for all the land on the east of the Weddell Sea with differentiation into various 'coasts' has not been adopted. The old tendency on polar maps to multiply 'land' reappears. The notes accompanying the maps are chiefly useful for their account of Admiral Byrd's recent work, accounts of which have not, so far, been readily accessible except in American newspapers. R. N. R. B.

The Organization of Knowledge and the System of the Sciences. By Henry Evelyn Bliss. Pp. xx + 433. (New York: Henry Holt and Co., 1929.) 5 dollars.

DR. BLISS'S book makes a twofold appeal. It is written by a librarian as a guide for librarians, and it also has a philosophical purpose. It criticises, in the latter part of the volume, all the better-known systems of classification of knowledge, and Dr. Bliss maintains that it is necessary for a librarian, as for anyone else dealing with the instruments of knowledge, to have a correct idea of its natural articulations in order to serve and co-operate to the best advantage with others working in various parts of the field. We are therefore inclined to turn first to the later chapters, although the earlier contain an impressive account of the increasing complexity of functional organisation of all kinds in practical life. The need of right organisation of thought to secure right organisation of action is the keynote of the book. It is a serious and very suggestive compendium.

Turning to the later chapters, which will be of most interest to the scientific reader, we notice that Dr. Bliss gives the first place among his 'almosters' to Ostwald, for his classification of the sciences into three main groups, with three or four main subdivisions in each. We are inclined to agree with him, mainly on the ground of clearness and simplicity. The three main groups are: (1) The formal sciences, under the concept of order; (2) the physical sciences, under the concept of energy; (3) the biological, under the concept of life. It proceeds, as all these systems do, from Comte's original, but it corrects and completes it. As knowledge grows, the boundaries will no doubt be again corrected in future. Dr. Bliss deserves our thanks for directing attention to the importance of the subject and spurring everyone to improving it. F. S. M.

Sleep and the Treatment of its Disorders. By Dr. R. D. Gillespie. (Minor Monograph Series.) Pp. ix + 267. (London: Baillière, Tindall and Cox, 1929.) 7*s*. 6*d*. net.

DR. GILLESPIE, who is a member of the younger school of British psychiatrists, is to be congratulated on producing a most readable and at the same time stimulating book on what is one of the most interesting problems of modern physiology—sleep. The author provides us with a wealth of clinical material and discussion. He wisely points out that the effects of loss of sleep are by no means so serious as are generally presumed; at the same time there is no question that in the mentally disordered, loss of sleep is a serious question. Experience in a mental hospital soon provides confirmation of this. His discussion of the theories of sleep is well balanced and well set out. In discussing the treatment of the psychoses by means of prolonged sleep, we should prefer to see somnifen described as a mixture of the diethylamin salts of diethylbarbituric acid and allylisopropyl barbituric acid and not as a single substance.

Intermediate Dynamics and Properties of Matter. By Dr. R. A. Houstoun. Pp. ix + 139. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 3*s*. 6*d*.

THIS book, which is of intermediate examination standard, deals very ably with those branches of physics that border on applied mathematics, and which present considerable difficulty to elementary students. The subject offers little scope for novelty of treatment, but has nevertheless been presented in an interesting manner, whilst the book also includes sections on various important branches such as rotational motion and gravitation, which are often omitted, although with little justification. The chapter on pumps has good accounts of the modern Hyvac pump and the McLeod gauge, and the chapter on the properties of matter a few paragraphs on diffusion, osmosis, and absorption of gases. One wishes that there were more equally good elementary texts in existence.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Constitution of Chromium.

THE first mass-spectra of chromium were obtained by means of accelerated anode rays. The results were very feeble and only showed one line of mass number 52 (NATURE, Sept. 22, 1923, p. 449). I have now been able to make experiments with a volatile compound of this metal, the solid carbonyl, $Cr(CO)_6$, kindly prepared for me by Dr. A. v. Grosse, of Berlin. The vapour pressure of this is low but sufficient for use in the ordinary discharge tube when suitable arrangements are made. The intensity of the beam of mass-rays has been so increased that not only has it been possible, by the use of fine slits, to obtain a value for the packing fraction of Cr^{52} but also, by the use of coarse slits and long exposures, to reveal no less than three new isotopes, and to determine their relative abundance photometrically as follows:

Mass number . .	50	52	53	54
Percentage abundance	4·9	81·6	10·4	3·1

The packing fraction of Cr^{52} is -10 with a maximum possible uncertainty of ± 3 (pts. per 10,000, $O^{16}=0$) a large negative value, as expected from the curve. Correcting for this and for the change to the chemical scale we get

Atomic weight of Cr
$=52{\cdot}011 \pm 0{\cdot}006$,

a value identical with that in use.

It will be noticed that the lightest isotope is isobaric with the doubtful Ti^{50} and the heaviest with Fe^{54}.

Cambridge, July 26.

Hydrogenised Iron of High Magnetic Permeability.

SINGLE crystals of iron produced some time ago in this laboratory by high temperature treatments in hydrogen [1] were found to have higher permeabilities than crystals grown by other methods.[2, 3, 4] Experiments soon showed that these high permeabilities were not the result of the large crystal size, but of the hydrogen treatment at the high temperature. As a result of further experiments great improvements in the permeability of iron have been obtained by heat treatments in hydrogen not resulting in large crystals, and values of initial and maximum permeabilities now repeatedly obtainable are 6000 and 130,000 respectively. For such specimens the coercive force is 0·05 gauss and the hysteresis loss for $B_m=14{,}000$ is 300 ergs/c.c./cycle. The magnetisation curves and hysteresis loop are shown in Figs. 1 and 2. For comparison, similar curves for ordinary annealed iron are also shown. Mechanically, this is the softest iron yet produced, having a hardness about the same as that of annealed copper.

These results have been obtained in cylindrical specimens of Armco iron one inch in outside diameter, ¾ inch in inside diameter and ¼ inch high, heat treated in moist hydrogen at between 1400° C. and 1500° C. for 12 hours. The specimens are then cooled to 880° C. or to room temperature, after which they are annealed at 880° C. for 2 hours. As a result of this treatment the specimens are etched as if by evaporation and have a grey colour probably due to a thin film of oxide. The grain diameter ranges from 0·1 to 2 mm. The magnetic properties are quite sensitive to mechanical strain but it has been found that deleterious effects due to overstrain, occurring at any time after the high temperature treatment, may be wiped out by a subsequent annealing at 880° C. This fact has been used to advantage where mechanical operations are desirable in the preparation of the specimens, the low temperature annealing being given after severe hard working of the material already treated at the high temperature. Experiments have also shown that the hydrogenising process may be applied in the melt.

Various experimenters have reported improvements in the magnetic properties of iron by heat treatments in hydrogen,[5, 6, 7] but the results obtained have not been so good as for specimens treated in vacuum [8, 9, 10] or nitrogen [6] or slightly oxidising atmospheres.[11] Such improvements as have been obtained have usually

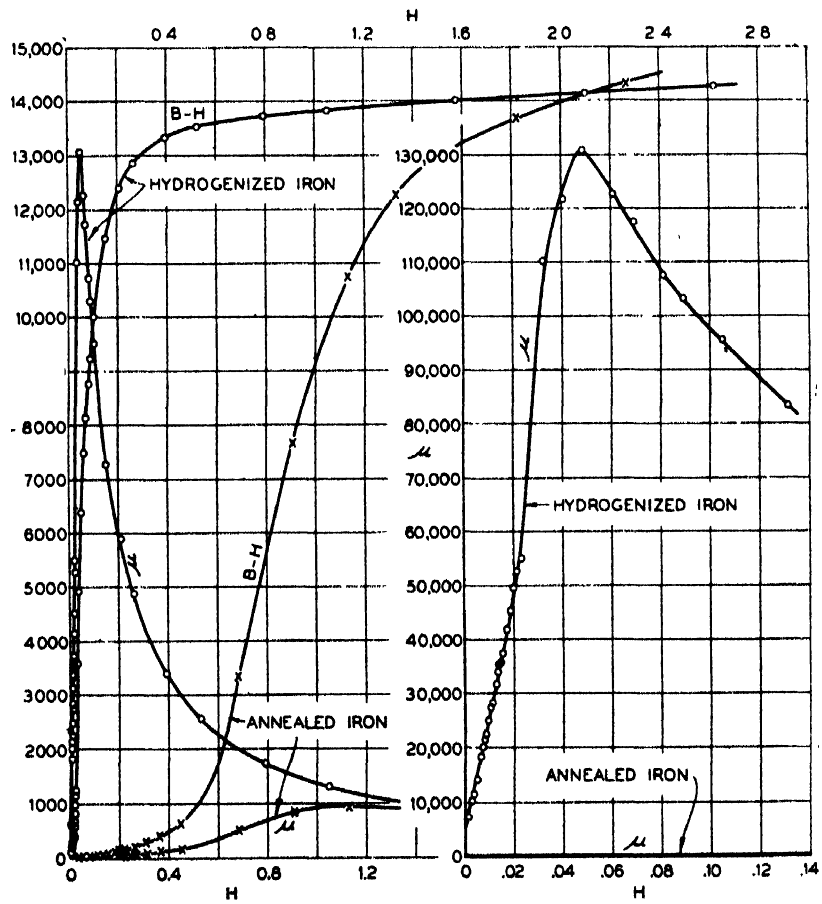

FIG. 1.

been ascribed to the removal of absorbed gases, reduction of the oxides, or decarburisation. Recently Yensen [12] reported high permeability in a specimen of carefully purified and vacuum treated iron. More recently Zeigler [13] reported similar results for a specimen consisting of several large crystals, from which he concludes that high permeability in iron is obtained only in single crystal specimens. Rogers has obtained

higher permeability than Yensen or Zeigler by melting iron in a low pressure carburising atmosphere, but makes no mention of the crystal grain size.[14]

It is believed that the high permeabilities obtained with hydrogenised iron are at least partly due to the absorbed hydrogen. This is shown by the fact that hydrogen treated iron of high permeability, when re-treated at a high temperature and in a good vacuum (about 10^{-8} mm.), assumes the permeability of ordinary iron treated in the high vacuum only. The drop in permeability of the hydrogenised specimen is presumably due to the loss of absorbed hydrogen. In other experiments the gas given off by the hydrogenised specimen was collected and analysed and found to be principally hydrogen. Determinations of the degree of deoxidation and decarburisation in hydrogenised iron are as yet incomplete.

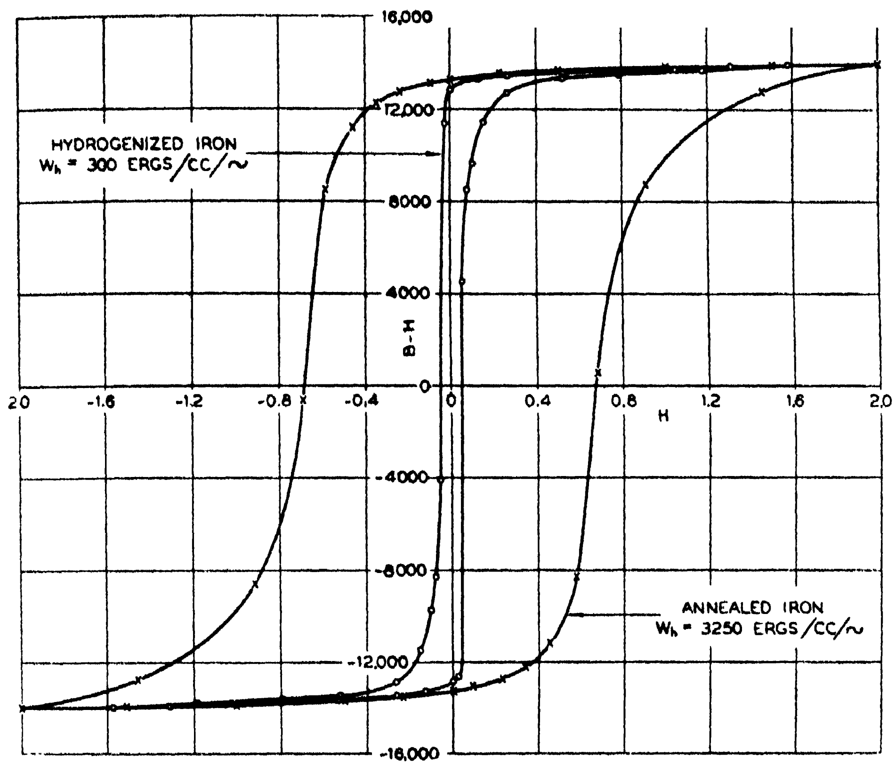

FIG. 2.

The factors which determine the results are temperature and time of treatment, pressure of hydrogen, and thickness of the metal. These are the factors which enter into Richardson's equation for diffusion and absorption of hydrogen by metals.[15] If the large magnetic improvements are dependent upon the absorption of an optimum quantity of hydrogen, it should be possible to obtain the same results by any suitable combination of the factors satisfying Richardson's equation. Experiments indicate that this is so.

Change of Wave-length of Light due to Elastic Heat Waves at Scattering in Liquids.

SOON after the discovery of the Raman effect, I attempted to find out whether in light scattered in various organic liquids the Raman lines, due to frequencies of the rotation spectrum, are present. These lines should be situated very close (probably within some fraction of an angström) to the incident line. In the course of these experiments a very interesting phenomenon was observed.

When the light λ4358 A. of a mercury lamp scattered at an angle of 90° by the liquids was examined by means of a highly resolving instrument (30 steps echelon grating), it was observed that besides the radiation with a wave-length equal to the incident one there were also other radiations of nearly the same intensity, the wave-lengths of which are symmetrically displaced relatively to the incident wave towards greater as well as smaller wave-lengths by a value depending upon the kind of liquid, but not differing greatly from 0·05 A. for all the liquids studied. The spectrogram of the scattered light has thus the shape of a triplet with a distance between the components of about 0·05 A. In the case of highly scattering liquids, such as toluene and benzene, I observed also some lines displaced by a multiple of this value. In the last-named liquids, up to three displaced lines on each side of the unmodified line, that is, 7 components in all, could be discerned, so that the farthest of them were at a triple distance, namely, c. 0·15 A. (The exposures could be so chosen that the components of hyperfine structure of line 4358 A. did not hinder the observations.)

These results were obtained last summer but their interpretation remained for some time not clear. Some considerations and further experiments (which will be published elsewhere) have led me to the conclusion that it is scarcely possible to regard the displaced components as Raman lines due to the rotational quanta.

Another explanation of the observed splitting of the scattered light is that this splitting is due to acoustic oscillations like those used by P. Debye (*Ann. d. Phys.*, **39**, p. 789; 1912) for explaining the variation of the specific heat of solids at lower temperatures. These elastic heat waves propagate in the medium with the velocity of sound and produce periodical variation of the amplitude of the scattered light, thus giving rise to two new frequencies:

$$\nu = \nu_0 \pm 2\nu_0 \frac{v}{c} \sin \frac{\theta}{2}. \qquad (1)$$

Here ν_0 is the frequency of the incident light, v is velocity of sound and c that of light in the medium, and θ is the angle between incident and the scattered rays.

This equation was given by Brillouin (*Ann. de Phys.*, **17**, p. 88; 1922) and also by Mandelstam

(*Jour. Russ. Phys.-Chem. Soc.*, **58**, p. 831; 1926), who has derived it from somewhat different considerations. The possibility of a change in light frequency according to equation (1) was also pointed out by Bogros and Rocard (*Jour. de Phys. et le Radium*, **10**, p. 72; 1929). However, their conclusion as to the absence of the phenomenon referred to seems to be erroneous.

The observed and calculated values of the splitting of two adjacent components are given in Table 1.

TABLE 1.

	$\Delta\lambda_{obs.}$ in A.	$\Delta\lambda_{calcul.}$ in A.
Aniline . . .	0·050 ± 0·005	0·056
Toluene . . .	0·047 ± 0·003	0·039
Benzene . . .	0·047 ± 0·003	0·036
Water . . .	0·045 ± 0·004	0·040
Ethyl alcohol . .	0·039 ± 0·004	0·033
Ethyl ether . .	0·035 ± 0·004	0·027

The agreement between $\Delta\lambda_{obs.}$ and $\Delta\lambda_{calcul.}$ is surprisingly good, and it remained to verify the existence of the connexion between angle θ and ν predicted by the theory. Such an experiment was necessary because the presence of undisplaced and multiple components seemed to contradict the above interpretation. (The liquids used in the investigation were from the firm of Kahlbaum and I have not purified or distilled them. I think, nevertheless, that the occurrence of the undisplaced component cannot be ascribed exclusively to contamination, dust, or stray light from the arc.)

The experiments with crystalline quartz (to be described in a separate communication) have shown that a crystal, in which the splitting according to equation (1) is mostly probable, gives a splitting of the frequency of scattered light similar to that of liquids.

It was found also that the scattering of a radiation of a mercury lamp λ4047 A. in benzene gives the same splitting as λ4358 A. The dependence of ν on θ was checked with benzene. Light rays scattered at the angles $\theta = 45°$ and $\theta = 135°$ were investigated. With $\theta = 45°$ the displaced components were expected to approach the undisplaced line so closely that under actual experimental conditions they could not be resolved. The spectrogram showed only a broadening of the undisplaced line. But with $\theta = 135°$ not only could the components predicted by equation (1) be observed, but also those displaced at multiple distances. All the components (the undisplaced one included) are equidistant and more separated one from another than at the angle 90°. The position of the undisplaced line remained unaltered at $\theta = 45°$ (the middle of the broadened line) and at $\theta = 135°$.

Table 2 gives averaged experimental values of $\Delta\lambda_{135°}$ and those calculated by equation (1), as well as ratios $\Delta\lambda_{135°}/\Delta\lambda_{90°}$ observed and calculated.

TABLE 2.

θ.	$\Delta\lambda_{obs.}$	$\Delta\lambda_{calcul.}$	$\left[\frac{\Delta\lambda_{135}}{\Delta\lambda_{90}}\right]_{obs.}$	$\left[\frac{\Delta\lambda_{135}}{\Delta\lambda_{90°}}\right]_{calcul.} = \frac{\sin 67° 30'}{\sin 45°}$.
90°	0·047 ± 0·003	0·039	1·32	1·31
135°	0·063 ± 0·002	0·050		

The agreement between observed and calculated values is quite satisfactory.

It may be concluded from the above that a close connexion between the splitting of wave-lengths of the scattered light and the elastic heat waves in the given medium does exist. These results may be regarded as a demonstration of the reality of Debye's waves and at the same time suggest a new 'spectroscopic' method for the determination of the velocity of sound in liquids and solids.

Equation (1) in the case of light scattering in liquids is to be replaced by the equation

$$\nu = \nu_0\left(1 \pm 2n\frac{v}{c}\sin\frac{\theta}{2}\right), \quad \text{where } n = 0, 1, 2, 3, \ldots$$

and the theory of light scattering by elastic waves is to be modified accordingly.

The number of components I could observe with my apparatus corresponded to $n \leq 3$, yet it is probable that components corresponding to $n > 3$ are also present. The broadening of the scattered line observed by Cabannes, Daure et Salvaire (*C. R.* **186**, p. 1533; 1928; **188**, p. 907; 1929), Gerlach (*Ann. d. Phys.*, **5**, p. 301; 1929) and Raman (*Proc. Roy. Soc.*, **122**, p. 23; 1929) can be explained, I think, at least partly by this phenomenon.

The existence of an undisplaced component ($n = 0$) is probably not connected with acoustic oscillations, that is, it is not due to rapid fluctuation of density caused by the propagation of elastic waves, but more likely to some comparatively slow fluctuation, maybe to the orientation fluctuations, the rôle of which in light scattering in liquids has already been discussed (for example, Raman and Krishnan, *Phil. Mag.*, **5**, p. 498; 1928). On the other hand, the occurrence of the undisplaced component may be due to the association of molecules in liquid. In this connexion it is interesting to note that when scattering is produced by a crystal (quartz), where such slow fluctuations cannot take place, an undisplaced component is, as it seems, absent or at least very weak.

The existence of multiple components ($n = 2, 3 \ldots$) may perhaps be ascribed to the scattering from 'elastic gratings' of harmonics.

The phenomenon described, as it seems, may prove of importance for the theory of light scattering as well as for the theory of specific heat of liquids and solids. It may also play an important rôle in Raman effect and probably give, as I believe, some explanation of the observed considerable broadening of Raman lines (Wood, *Phil. Mag.*, **6**, p. 1282; 1928; Langer and Meggers, *Phys. Rev.*, **33**, p. 115; 1929).

In conclusion, I wish to point out that the above experiments may be regarded as an illustration of the change of wave-length of light produced by the modulation of the amplitude of oscillations—a problem which has attracted attention of physicists for a long time (Wood, "Physical Optics", p. 407; 1905; Cotton, *Le Radium*, **8**, p. 404; 1911; Rupp, *Zeit. f. Phys.*, **47**, p. 72; 1928).

Tercentesimal Temperature and the Kelvin Absolute Scale.

IN NATURE of July 19 a review entitled "Discursive Meteorology", meaning as I think 'discursive physics', asks a question to which I ought if possible to find an answer. The reviewer writes: "Some of his own usages arouse criticism, in particular, that of *tt* to denote absolute temperature (not only in the form 300° *tt*, but also in formulæ); why should not meteorologists adopt the now growing physical practice of writing 'K' to denote the Kelvin absolute scale, just as 'C' and 'F' are used for the Centigrade and Fahrenheit scales?"

To begin with, the answer is categorically in the negative.

(1) I have never used *tt* to denote absolute temperature. (2) So far as I know I have never used the form 300° *tt* and never shall; if it is in any one of my volumes it is a misprint; it shocks my æsthetic sense to see

it printed in NATURE. (3) I have never known a meteorologist use the Kelvin absolute scale to express the temperature of the air numerically.

What many of us use is the temperature as read on an ordinary thermometer with 273 added, either by the instrument maker, the observer, or the computer. The result is often loosely called absolute temperature, and may be so called anywhere except at one's writing-table. With rather surprising emphasis, the most incisive of my scientific friends insist upon drawing a very marked distinction between it and the absolute scale, a distinction which I find it impossible to repudiate or ignore though numerically (about a tenth of a degree) it is of no importance.

Equally I find it impossible to regard the so-called absolute temperature as something of the same order as a scale, be it 'C' or 'F' with an arbitrary zero. The one connotes energy; the others connote only the reading on a scale and have no dimension. To my mind there is the same difference betwen the two as there is between volts, amperes, or microfarads and the number of degrees of deflection of a spot of light on the screen of a galvanometer.

I have called the measure of energy by C + 273 the 'tercentesimal temperature'. To-day, for the atmosphere, I would prefer to call it the thermancy and leave temperature to retain its popular usage; but, so far as I am concerned, the opportunity for that has been allowed to go by.

While I was writing discursive meteorology or discursive physics, I came upon a paragraph in a preface by Prof. Ernest Barker of a book on national character which appealed to me so strongly that I may be excused for quoting it.

"It is impossible to think clearly with Protean terms; and the first necessity of argument is the use of clean words which are always used to denote the same things and connote the same attributes. To use a single word when three or four different ideas are in question and to use it now for one and now for another of the ideas, is a confusion of ideas and of argument." From that point of view I was quite pleased with 'tercentesimal temperature' as distinguishing what I was using from veritable absolute temperature as well as from 'C' or 'F'. I thought it a clean, crisp note direct from the International Bank of Scientific Intelligence, Ltd., which still keeps my small account. It never occurred to me to regard it as a bit of old newspaper picked up from the scrapheap of abortive science, and criticism notwithstanding, I do not so regard it even now.

As to *tt* for a symbol of quantity, I have only to say for that, that it is new and crisp and quite useful. So is another piece of apparent duplicity, namely, *bb* for pressure-gradient in absolute units. Any other symbol that is used for either has been overworked for years. If the reviewer or any other of my scientific friends who have to face the terrible discursiveness of the physics of the atmosphere will give such suitable double letters a trial, with the understanding that always and everywhere they will carry exactly the same meaning, he will find them, as I have done, extraordinarily convenient. NAPIER SHAW.

Isotope Effect in the Spectrum of Boron Monoxide: Intensity Measurements and Structure of the β-Bands.

MEASUREMENTS of the intensities of the lines in four bands in the β system of boron monoxide excited by active nitrogen have enabled the intensity ratios of the $B^{11}O$ and $B^{10}O$ bands to be determined. Each band has been measured on two plates, and the intensities of the corresponding lines in the two isotopic bands compared. The following table gives the mean ratio of the lines for each of the bands, for each of the two plates:

Band.	$1\rightarrow5$.	$2\rightarrow5$.	$2\rightarrow6$.	$3\rightarrow7$.
Intensity $B^{11}O/B^{10}O$.	3·36	3·34	3·50	4·30
	3·46	3·22	3·17	4·38
Mean . . .	3·41	3·28	3·34	4·34

The first three agree quite well, but differ from the result for $3\rightarrow7$ by an amount considerably greater than the probable error; it is most unlikely that the discrepancy is due to 'blending' with lines of other bands. The result appears to show a real difference in the intensity ratios of the isotopic bands for different vibration transitions. It is possible that the difference is due to some selective excitation properties of active nitrogen.

These results may be compared with the isotope ratio calculated from the atomic weight of boron. Taking 11·0110 and 10·0135 for the atomic masses of B^{11} and B^{10} respectively (F. W. Aston, *Proc. Roy. Soc.*, **115**, 487; 1927), and 10·82 for the atomic weight of boron (German Atomic Weights for 1927), the calculated abundance ratio of the isotopes is 4·22 : 1. There appears to be a possibility that the atomic weight of boron varies according to the source from which it is obtained (H. V. A. Briscoe and P. L. Robinson: *Jour. Chem. Soc.*, **127**, 696; 1925), and since the atomic weight of the boron used in the intensity measurements has not been determined, the calculated isotope ratio must be regarded as uncertain.

It appears from the above measurements that, in this case at least, the intensity ratios of isotopic bands do not give a true measure of the relative abundance of the isotopes as they occur in nature.

STRUCTURE OF THE β-BANDS OF BORON MONOXIDE.

It has been known for some time that only one series of lines occurs in the β bands of boron monoxide excited by active nitrogen, whereas in the same bands excited in the arc, a second series of approximately equal strength appears (R. S. Mulliken, *Phys. Rev.*, **25**, 259; 1925). It was suggested by Mulliken (loc. cit.) that the P branch was missing in both cases, that the two series in the arc were electronic doublets constituting an R branch, and that only one member of the R branch doublet was excited in active nitrogen.

The arc bands have been examined with a Hilger $E1$ quartz spectrograph, and it was found that the lines in both series are very close doublets, the doublet separation increasing with distance from the head. The frequencies of the lines in the $0\rightarrow1$ and $0\rightarrow2$ bands have been measured (neglecting the fine structure), and good agreement of the combination differences for the excited state of the two bands is found, if the two series are assumed to be P and R branches, the P branch being the series which appears only in the arc. The lower state combination differences for the $0\rightarrow2$ band then agree very well with those for the $0\rightarrow2$ band in the α system (W. Scheib, *Zeit. f. Physik*, **60**, 74; 1930), which has the same final state as the β bands.

From these considerations, it appears practically certain that doublet P and R branches of approximately equal strength occur in the arc β bands, whereas (see Mulliken, above reference, for possible exceptions) only the R branch occurs in the bands excited in active nitrogen; it is not known whether this branch is double or not, as the rotation structure is not sufficiently developed in this case to enable the doublets to be resolved with the instrument employed.

From the above measurements, a preliminary value of $B'_0 = 1{\cdot}53$ cm.$^{-1}$ is obtained. The values of B'' are already known from the work of Scheib (loc. cit.), since the α and β bands have the same final state.

Sputtered Nickel Films and the Synthesis of Ammonia.

I HAVE recently found that when a film which has been sputtered from a nickel cathode in an atmosphere of nitrogen is afterwards heated to 150° C. or more in hydrogen, ammonia is produced. The process undoubtedly consists in the reduction of a nitride of nickel formed in sputtering: the quantity of ammonia —10-20 mgm. for a film of perhaps 200 sq. cm.—checks reasonably well with the amount of nitrogen absorbed in sputtering. Heating in a large excess of hydrogen, with added nitrogen, has not as yet been found to increase appreciably the yield of ammonia, so the process does not appear to be catalytic in the ordinary sense—for the pressures and temperatures tried so far.

Of course, the production of ammonia from nitrides is common (cf. the Serpek process), and the nitride of nickel is not unknown (see, for example, Beilby and Henderson, *Jour. Chem. Soc.*, **79**, 1251; 1901: Vournasos, *C.R.*, **168**, 889; 1919). The chief novelty in the present work, aside from the method of production of the nitride, is the comparatively low temperature at which the reaction takes place. This is probably due to the nitride being produced in sputtering in a very finely divided form (although doubtless still crystalline, cf. Ingersoll and Hanawalt, *Phys. Rev.*, **34**, 975; 1929).

It may be pointed out that the sputtering process—when used under conditions such as the present, of relatively high gas pressure and low voltage—offers a method, hitherto little used, for the formation of many unusual compounds or quasi-compounds. With the metal (probably) in the vapour state and the gas largely excited, combinations are certainly to be expected (cf. v. Hippel, *Ann. d. Phys.*, **81**, 1072; 1926), if they are at all possible. Conditions of current density and gas pressure are likely to be somewhat critical. In the present case nitrogen is most rapidly absorbed in sputtering when the pressure is about 0·5 mm., with a current density around half a milliampere per sq. cm. of film surface, at 1500 volts. Too high a current, or insufficient cooling, breaks down the compound as fast as formed. Heating to 300° C. decomposes this nitride, driving off the gas and leaving a crystalline film of metallic nickel. If pure compounds are to be formed in this way, the cathode should be in a thin strip form which can be given a preliminary heating to redness for some time, as otherwise the gas released from the metal in sputtering forms a serious source of contamination.

Spitsbergen Whale Fishery of the Seventeenth Century.

As is well known, in the seventeenth century a right-whale fishery was prosecuted in the inlets of West Spitsbergen, the whales being caught by boats launched from the shore. Were the whales caught at this fishery Greenland whales, as is asserted, or were they, as seems more likely, Atlantic whales?

In 1827, on May 14, Parry [1] found Mauritius Bay, on the shore of which Smeerenberg, the Dutch whaling station, stood, still frozen over, the edge of the land ice or land-floe extending across its mouth from Hakluyt's Headland to Vogel Sang; in 1880, on July 20, the late Mr. Leigh Smith [2] found Fair Haven blocked with ice; and last year in June, according to a Danish Meteorological Office report,[3] Foreland Sound was still frozen over.

Taking the foregoing and certain other facts connected with the ice into consideration, the inshore fishery of the seventeenth century must have been prosecuted in July and August, months in which the inlets of West Spitsbergen are usually free from 'land ice', that is, the ice that forms *in situ* in the winter months. Until this kind of ice breaks and drifts away, the fishery could not be prosecuted by boats launched from the shore.

The Greenland whale is a migratory animal, keeping amongst or in the near vicinity of the polar ice and in water having a temperature never much above its freezing-point. According to the log-books of Scoresby, senior, it was only seen near Spitsbergen in April. In May and June it had to be looked for amongst or near the ice half-way between Spitsbergen and Greenland, and even this situation it usually deserted in the latter month. In July and August it had usually to be looked for in a lower latitude near the Greenland coast, but in that situation it was seldom seen except in limited numbers and only when there was plenty of ice.

The Atlantic whale is also a migratory animal, migrating north in summer and south in winter, but it prefers ice-free waters with a temperature well above their freezing-point. In recent years it has been seen so far north as Iceland and Bear Island; and west of Spitsbergen, where the temperature of the water is unusually high, it may quite well have gone still farther north.

Distribution of the Pigmy Hippopotamus.

UNTIL Major Hans Schomburgk's search in 1911-12 for the headquarters of the pigmy hippopotamus (*Choeropsis liberiensis*), little was known of its distribution except that it hailed from the country to which it owes its specific name. Schomburgk found that it extended from the coastal belt of Liberia back to the boundary of French Sudan, but how far it spread along the coast into Sierra Leone and French Ivory Coast he could not discover ("Distribution and Habits of the Pigmy Hippopotamus", in *17th Ann. Rep. New York Zoo. Soc.*, 1912 (pub. 1913), pp. 113-120). His farthest east record is from Du Queah (Dukwia) River, on the boundary between the Mamba and the Bassa Country, about 10° 15′ W. long.

Two skulls, recently presented to the Royal Scottish Museum by Mr. J. B. I. Mackay, were given to him in 1928 by the chief of Abo. The animals to which these skulls belonged lived in marshy ground of limited area not far from the banks of the Niger and within a hundred miles of its mouth, more than a thousand miles west of previous records. I do not specify the locality more definitely, because, although the animals are sufficiently numerous to warrant the attentions of a professional native hunter who spends most of his time in the dry season hunting them, they might readily be exterminated owing to the circumscribed area inhabited, and in spite of the moderate protection granted by law.

There is a possibility of geographical differentiation in such a colony, especially if it be a very isolated outpost. I add, therefore, the chief dimensions of the skulls, in mm.:

Length along face, premaxilla to occiput, 310, 311; condylobasal length, 297, 299; zygomatic breadth, 185, 196·5; least inter-orbital breadth, 93·5, 96; nasal, 152·5, 147·5; greatest combined breadth of nasals, 38·5, 40; occipital depth (median), 89, 86; mandible, 242; mandibular tooth row, including canine, 180·5; ditto excluding canine 144; maxillary tooth row, including canine, 164, 166·5; ditto excluding canine 136·5, 142; 3rd upper molar, 21, 22; 3rd lower molar, 27.

In the above list the first number refers to skull 1929.176.1, the second to skull 1929.176.2, of which the lower jaw is missing. James Ritchie.

Royal Scottish Museum,
Edinburgh, July 7.

X-Ray Spectra and Chemical Combination.

The element sulphur offers a very interesting case for the effect of chemical combination on X-ray spectra. Lindh has already established remarkable changes in the K-absorption edges of this element with varying valency (see Siegbahn: "Spectroscopy of X-rays", pp. 146-147). The $K\beta$ lines of this element also show peculiar changes, especially regarding relative intensity and structure of β_1 and β_x lines in various chemical compounds of sulphur. In the course of a study of the X-ray spectrum of sulphur and its compounds, I have made the surprising observation that one line, with the wave-length 5043 X.U. (apparently identical with the $K\beta_3$ line listed by Hjalmar), is emitted by certain sulphur compounds, but not by pure sulphur or by certain other chemical compounds of this element.

It has been found that sulphates of lithium, sodium, potassium, rubidium, cæsium, silver, and mercury, as well as the sulphides of sodium, potassium, strontium, barium, and cadmium, give quite an intense $K\beta_3$ line, whereas in the sulphides of copper, silver, magnesium, zinc, mercury, lead, and molybdenum this line is entirely suppressed. For sulphates of copper and magnesium and the sulphide of calcium a faint indication of this line is obtained. In all cases a copper anticathode was used.

The ordinary spectral lines so far known are all of atomic character, that is, they are emitted on transitions between levels belonging to the atom of the free element. In some cases, especially with light elements, an influence on the wave-length and the structure of the lines by adjacent atoms has been found. The observations here reported seem to indicate the existence of a new type of X-ray lines arising from transitions within a *molecule*.

Details of this communication will be published elsewhere. G. B. Deodhar.

Physical Laboratory,
University of Uppsala, July 11.

Mortality amongst Plants and its Bearing on Natural Selection.

In a communication in Nature of May 31, p. 817, Prof. E. J. Salisbury describes some exact quantitative observations on the mortality which takes place in the seedling condition of flowering plants, and he points out the bearing of these facts upon natural selection. The sycamore furnishes another good instance of this high infant mortality, since almost every year the tree produces an abundance of viable seeds. The winged indehiscent fruits provide a very efficient means for seed-dispersal, and seedlings bearing the first pair or two of young foliage leaves are plentiful in almost every situation throughout the summer. It is well known from experience that only a very small fraction of these seedlings will ultimately survive, or even pass beyond the two-leaved stage, and grow into trees.

Some light might be thrown upon the problem as to which, if any, characters possessed by the seedlings are of help in bringing about this apparent survival of the fittest, if observations were made upon the *causes* of this excessive mortality. Is it due, for example, to unfavourable climatic conditions, too much or insufficient light, overcrowding, insect or other animal enemies, fungus pests, etc.? Information upon this point, which so far as I am aware has not previously received attention, cannot fail to be of interest. A. W. Bartlett.

Simultaneous Electronic Transitions in X-Ray Spectra.

In a letter to Nature of Oct. 26, 1929, by D. Coster and M. Wolf, the results were published of some investigations on the fine structure of X-ray absorption edges of copper and zinc.

Whereas with copper a very complicated fine structure was easily obtained, in the case of zinc, in the beginning, no fine structure at all could be observed. Mr. Suekichi, however, recorded a fine structure of the zinc-K-edge of zincblende when this crystal was used as analysing crystal (Nature, Mar. 29, 1930, p. 509). In the meantime, in continued experiments, I have succeeded at last in observing also a fine structure in the case of zinc, when metallic zinc foil was used as absorbing screen. This fine structure of zinc, however, seemed to be less pronounced than that of copper.

Experiments are in progress to measure the variations in the absorption coefficients in the fine structure range of the K-edges of copper and zinc in order to draw more definite conclusions about the probability of simultaneous electronic transitions in both elements.

The Quantum Theory of Chemical Valence.

Dr. J. C. Slater has shown in a most valuable paper (*Phys. Rev.*, Vol. 34, p. 1293; 1929) that one can develop the complete theory of atomic states (multiplets) in a simple way without the application of the methods of the group theory. This is of considerable importance; for the difficulties of these methods interfere greatly with the understanding of the simple relationships which are derived. I should like to point out (no doubt Slater has already done so himself) that one can treat the theory of the interaction of several atoms in the same simple way and indeed more exactly than merely to the first approximation. One obtains the results first obtained by Heitler and London with help of the methods of the group theory and, furthermore, the valence forces between atoms in all various excited states. In the interest of the further propagation of Slater's ideas, I shall in the near future publish these considerations in greater detail in the *Zeitschrift für Physik*.

M. Born.

The Great Barrier Reef of Australia.*

By Dr. C. M. YONGE, Leader, Great Barrier Reef Expedition.

AUSTRALIA possesses in the Great Barrier Reef the largest and most impressive series of coral reefs in the world. The realisation of the unique opportunities so presented for scientific research—geological, geographical, and biological—led in 1922 to the formation of a Great Barrier Reef Committee with headquarters at Brisbane. Its chief promoters were the Right Hon. Sir Matthew Nathan, at that time Governor of Queensland, and Dr. H. C. Richards, professor of geology in the University of Queensland. Valuable work of a geological and geographical nature was carried out, and then, in 1927, following representations by Sir Matthew Nathan on his return to Great Britain, a British Association Committee was formed to organise an expedition for the biological investigation of the Great Barrier. To the expedition, which sailed in May 1928, was attached a geographical section organised and largely financed by the Royal Geographical Society.

The position of the coral reef controversy at that time can best be realised by a study of Prof. W. M. Davis's book, "The Coral Reef Problem", published in 1928. From the time of Darwin it has been regarded as essentially a geographical problem. As a matter of common experience it is known that reef-building corals live only in water 30 fathoms or less in depth and in temperatures at or above 20° C. Although Madreporarian corals flourish even to the fringe of the polar oceans and in the deep seas, they never form true reefs—unless we include the banks of *Lophohelia prolifer* in the deep waters of the Norwegian fjords—except in the tropics. Where in these regions they occur depends on the presence of a suitable substratum, namely, a platform not deeper than 30 fathoms, and where there is never any serious admixture of fresh water or extremely heavy fall of silt. Cold currents from the poles or the upwelling of cold water from the deep seas inhibit their growth and are responsible for the absence of coral reefs from the western coasts of the great continents.

Darwin divided coral formations into fringing reefs, barrier reefs, and atolls. The first develop in the shallow waters round the coasts of continents and continental or volcanic islands, and their origin is clear and undisputed. The others grow up far from land, though in the case of the former in clear connexion with it, and the mystery of the origin of the platform on which they have developed *is* the coral reef problem. Little is known of the biology of corals; few have been examined when alive, and the long-continued and careful investigations necessary for the full elucidation of their life histories, growth, food and manner of functioning, and the numerous factors which control these, have seldom been attempted. It was to fill in some degree this great gap in scientific knowledge that the expedition worked. The results it obtained from investigations into the nature, organisation, and

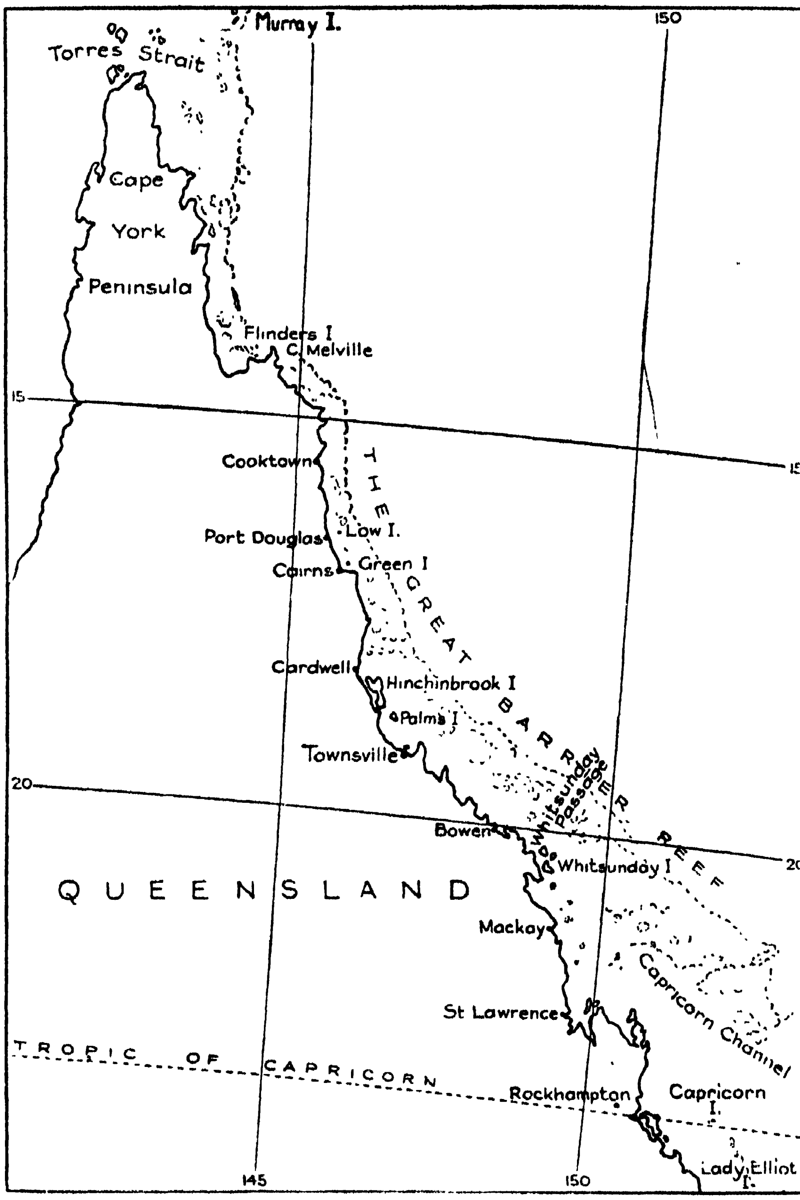

FIG. 1.—Map of the Great Barrier Reef. (Map by Mr. J. A. Steers, by kind permission of *Discovery*.)

* Friday evening discourse delivered at the Royal Institution on May 16.

life of the unique marine communities known as coral reefs will constitute its main contribution to the science of marine biology.

The series of reefs which are grouped together as the Great Barrier Reef of Australia run roughly parallel to the north-east coast and, in the words of Jukes, one of its early investigators, " may be said to commence with Breaksea Spit, in S. lat. 24° 30′, and extend to Bristow Island, on the coast of New Guinea in S. lat. 9° 15′ ". Measured in a straight line, this is 1260 statute miles (Fig. 1). It must clearly be understood that these reefs do not form an unbroken chain, like a gigantic breakwater, although they certainly possess the function of one by sheltering the coastal waters from the Pacific storms. The term Barrier Reef is here one of convenience rather than accurate description. We are dealing with a vast series of reefs which have grown up on a shallow submarine platform of immense length and, in its southern portions, of great width.

The most southern reefs, immediately north of Breaksea Spit, are a series of isolated islands, first Lady Elliot Island and then the Bunker and the Capricorn Groups, all in the region of the Tropic of Capricorn. The reefs are oval in outline, each with a sand cay covered with dense vegetation upon it. Although they extend so much as 60 miles from the coast, none of the islands is on the edge of the platform. The Capricorn Group is separated from the remainder of the Barrier Series by the Capricorn Channel, which is considerably deeper than the waters between the Barrier and the mainland (which seldom exceeds 20 fathoms) and through which vessels pass to enter the steamer channel within the Barrier which leads to Thursday Island and the ports of the Far East.

The Barrier Series proper may be said to begin with Swain Reefs, a confused mass of reefs fifty miles wide and separated by a distance of about one hundred miles from the mainland. These reefs are little known; they are separated from one another by intricate channels, shallow and full of coral patches. They are in no sense barrier reefs. Similar reefs, but not extending over such wide areas and coming gradually closer to the coast, and separated by occasional channels wide and deep enough for ocean-going vessels to negotiate, comprise the southern half of the Great Barrier.

North of Cairns, about latitude 17°, the reefs really do begin to assume the character of a true barrier. The submarine platform becomes narrower and the reefs extend to its outermost margin, so that in places depths of 1000 fathoms are reached only a few miles beyond the reef. This was the region in which the expedition worked, the headquarters, Low Isles, being some fifty miles north of Cairns. The lagoon channel narrows from twenty miles at Cairns to a little more than five opposite Cape Melville, 200 miles farther north, beyond which it becomes much wider owing to the deep inlet of Princess Charlotte Bay. The reefs, however, continue to run roughly parallel to the coast for another 150 miles, but north of Cape Direction the coast runs north-north-west to Cape York, but the reefs almost due north, so that they are separated by a channel eighty miles wide from the far north of Cape York Peninsula.

Within the Torres Strait, itself a shallow water area, the Barrier forms the outer margin of the vast series of reefs which extend between the coasts of Cape York Peninsula and New Guinea.

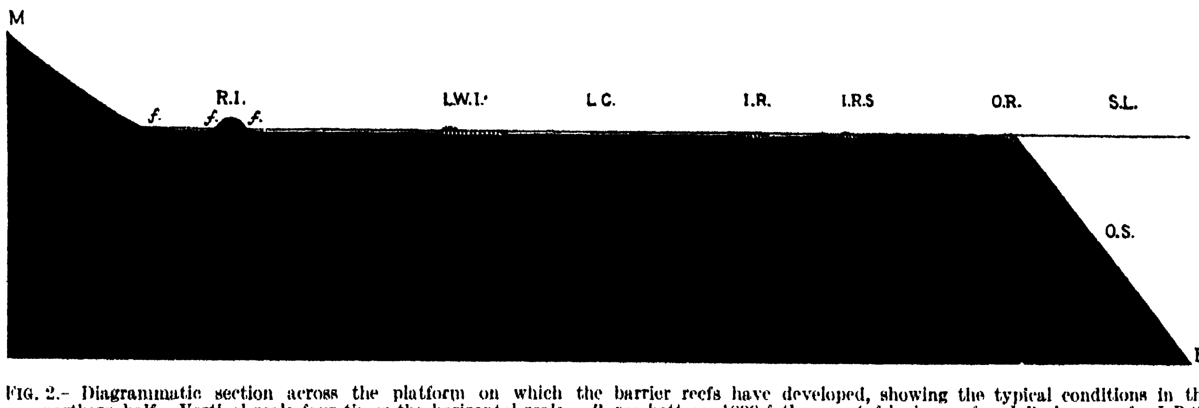

FIG. 2.—Diagrammatic section across the platform on which the barrier reefs have developed, showing the typical conditions in the northern half. Vertical scale four times the horizontal scale. *B*, sea bottom, 1000 fathoms; *f*, fringing reefs; *I.R.*, inner reef; *I.R.S.*, inner reef with sand cay upon it; *L.C.*, lagoon channel 16-20 fathoms; *L.W.I.*, low wooded island with vegetated sand cay; *M.*, mountain, 2500 feet high, on mainland; *O.R.*, outer reef, true barrier; *O.S.*, outer slope of platform; *R.I.*, rocky island, 400 feet high with fringing reefs; *S.L.*, sea level.

Such, then, is the general disposition of the Great Barrier. The origin of the great submarine platform on which it stands is, and is likely to remain so for many years to come, a great geographical problem. Mr. J. A. Steers, the leader of the Geographical section of the expedition, has summarised elsewhere [1] the various opinions that have been held. Some have thought that it has been cut by the seas, possibly when the level of the sea was lowered during the glacial periods, others that it has been formed by a sinking of the land. Upholders of the latter—and more probable—view are divided into those who regard the platform as having been built up by corals, that is, a fringing reef which has grown outwards owing to a sinking of the coast, as Darwin postulated, and others who think that the coral forms only a thin veneer over the surface of a pre-existing platform formed by the submergence of a coastal plain. There are various views as to the manner in which this submergence may have taken place, but Mr. Steers, with the majority of recent workers on the subject, ascribes it to faulting.

The shallow lagoon channel contains innumerable islands. Many of these are rocky, high, richly vegetated, and of great beauty. They show every indication of having originally formed part of the land mass near them and constitute important evidence in favour of land subsidence. Most of them are close to the coast, but Lizard Island, seventy miles north of Cooktown, is sixteen miles from the land. These islands, like the mainland coast wherever suitable, are usually bordered with fringing reefs.

In the far north of the Barrier lies a small group of extinct volcanic cones, the three Murray Islands and Darnley Island. They have no connexion with the continental mass, and in general character and richness of vegetation resemble much more the volcanic islands of the Pacific, such as Samoa, Tahiti, or Hawaii.

The northern half of the lagoon channel is dotted with coral islands, of which Low Isles was a typical example. Trees are abundant and are responsible for the name, Low Wooded Islands, which is given to them in the "Admiralty Pilot". Owing to their protected position and proximity to the land, they have many unique features. The contours of the reefs are influenced by the South-easterly Trade wind which blows with steady force for nine months in the year. They are crescent-shaped with the point of the convexity facing south-east, the reef on this side descending quickly into deep water. On the lee side the water deepens much less quickly. As a result of abrasion by the waves on the weather side, fragments of coral are broken off and carried round the reef to be accumulated in the area of 'dead' water behind it. Here in time a sand cay is formed which, at first entirely at the mercy of any change in winds and currents, gradually becomes consolidated by vegetation and the formation around it about low water mark of a thick zone of beach rock. This is sand cemented together by calcium carbonate precipitated among it when rain water which has fallen on the surface of the cay seeps through it at low tide and is evaporated at its surface.

On the windward side great banks of shingle accumulate and frequently form northward projecting spits. Behind the cover of these shingle banks mangroves have established themselves until, as on Low Isles, an almost impenetrable forest of *Rhizophora mucronata*, fringed at a slightly higher level with *Avicennia officinalis*, is formed. Infrequent openings amongst the tangled mass of strut roots give passage into central lagoons the black mud bottoms of which are exposed at low tide. On the outer side the mangroves are being destroyed by the advancing line of shingle, on the inner side they are advancing over the reef flat towards the sand cay, and in certain islands, notably the Turtle Group, the two seem to have fused, the mangroves growing round the central sand cay.

FIG. 3.—The reef edge at Northwest Island, Capricorn Group, exposed at low water spring tides. The surface of the reef is cemented with *Lithothamnion* and has little living coral, which flourishes on the outer slopes. (Photograph by M. J. Yonge.)

The shallower water on the lee of the reefs is full of coral patches, flat-topped pinnacles of living coral. Sudden storms from the north, sometimes of cyclonic fury, which occur during the summer months, break away this coral and throw great boulders high on to the reef surface, forming a boulder tract along the northern shores. Boulders are also carried on to the south-easterly side of the reef, but not to the same extent. The general

surface of the reef flat, which is some four feet above datum line, is composed for the greater part of dead coral, but there is an abundance of animal and plant life in the numerous pools and particularly in the wide moat which is enclosed by the shingle rampart. Around the sand cay there are wide sand flats, while the mud of the mangrove, which supports a fauna and flora totally different from that of the reef flat proper, extends for some distance westward of the swamp itself.

The Barrier reefs may be divided, in the northern half in particular, into an inner and an outer series. The inner ones are a little higher than the outer reefs and not infrequently have sand cays, smaller and seldom vegetated, upon them. The vegetation consists of coarse grass and creeping convolvulus, and such cays are often the haunt of vast flocks of sea birds, sooty terns, or wide-awakes, and noddies predominating. Even at half-tide the outline of such reefs is frequently indicated by the great boulders which fringe them. These 'nigger' or 'negro heads' have been the subject of much controversy, early workers on the Barrier considering that they have grown *in situ* and were thus the evidence of reef elevation. There can be no doubt, however, that, like the boulders on Low Isles, they have been cast up by cyclones. Although present on the southern and central reefs, they are absent from the reefs about Murray Island, which is north of the cyclone belt.

The outer reefs are exposed to the full force of the Pacific, on which there is usually a great swell even in the calmest weather. Their outer slopes, clothed with living coral for the upper 30 fathoms, descend at a sharp angle to hundreds of fathoms. The reef crest, never exposed except at the lowest spring tides, is cemented by *Lithothamnion*, which always, apparently, flourishes best in regions where the surf breaks, into a solid rampart, on which only a few stunted corals, sessile molluscs and the like, manage to lead a precarious existence. Boulders of a gigantic size are occasionally to be seen; smaller ones will be rolled over the crest into the shallow water in the lee. Here, as in the lee of all reefs, there is a great abundance of coral growth, the size of the coral-covered boulders increasing as the water deepens.

These outer and inner reefs of the Barrier Series all show the same moulding by the South-easterly Trade winds, though in the case of the former it is not so apparent; they frequently stretch almost due north and south along the edge of the submarine platform, sometimes, as in the case of Ribbon Reef, for a length of fourteen miles, with only a curling back at the ends to show the effect of the prevailing wind. The reefs of the Capricorn Group, south of the Trade-wind belt, are not moulded in this way. The occasional deep channels between the outer reefs which give passage for large vessels from the Pacific into the lagoon channel, are kept open by the effect of tidal currents which run in and out with the flood and ebb tides like a mill-race, with a speed of not less than 8 knots.

The accompanying section (Fig. 2) across the platform shows the distribution of the fringing reefs, Low Woody Islands, rocky islands, and inner and outer 'Barrier' reefs, and the sudden descent into deep water off the edge of the platform.

FIG. 4.—Living coral exposed at low water spring tides in the 'anchorage' at Low Isles, showing the wealth of coral which grows in the shallow water in the lee of reefs. (Photograph by M. J. Yonge.)

Between thirty and forty genera of corals and well over one hundred species are concerned with the formation of these reefs. Probably no region in the world is so rich in coral species. They are assisted in their building action by coralline algæ, *Lithothamnia*, and by the minute calcareous skeletons of foraminiferans, and also to a smaller extent by the dead shells of molluscs—foremost amongst which is the giant clam, *Tridacna gigas*, which may attain a length of four and a half feet and a weight of four or five hundredweight. The growth of corals, the study of which formed an important part of the programme of the expedition, is greater than might be expected, certain species doubling their size in six months. Such powers of growth are necessary, however, if the reefs are even to maintain themselves. They are continually being battered by the seas, they are subject to the destructive action of a host of molluscs and worms which bore through their skeletons until these are honeycombed with their tunnels, and even algæ play some part in this destructive process. Exposure during low spring tides invariably kills corals which have grown above a certain height, thus maintaining the level surface of the summit of the reefs. Near the coast the fringing reefs are in constant danger of being destroyed by great floods of fresh water running off from the land during the summer rainy season. A striking example of this was furnished in 1918 when Stone Island Reef near Bowen was completely destroyed after 36 inches of rain had fallen in eight days.

The nature of communities known as coral reefs is too great a subject to discuss here; a detailed census of the population of different reefs and different zones of them was undertaken by the expedition. Corals themselves, it was found after careful studies, live on the minute floating animal life of the seas—the zooplankton—for the capture and digestion of which they are admirably equipped. They contain within their tissues vast numbers of minute algæ, zooxanthellæ, which dispose of the waste products of coral metabolism, and provide, as a result of their photosynthetic activities, abundant supplies of oxygen (possibly of vital importance in view of the density of the population on a typical reef), but do not, as has been thought, play any great part—if any at all, the matter is still *sub judice*—in the nutrition of the coral.

The conditions in the seas which bathe the reefs are of primary importance; they control the food supply and the 'climate'. The changes in the physical condition and in the principal chemical constituents—notably those which can be utilised as food by plant life—are far smaller than occur in temperate seas. The plant and animal plankton is also much poorer and shows fewer fluctuations, but there is no reason to doubt that the latter provide all the food required by the corals, which, in spite of their apparent bulk, are really thin sheets of living matter spread over a great surface of calcareous skeleton. Life on the sea bottom, as revealed by dredging and trawling, is abundant where the bottom is rocky or sandy, but very poor in the inner parts of the platform where it is covered with a soft mud. Fish, not unnaturally, are abundant in the former regions and scarce in the latter.

The reefs are a source of both profit and loss to Australia. They are rich in a number of commercially valuable animals, notably pearl shell—the smaller black-lip (*Pinctada margaratifera*) everywhere and the large gold-lip (*P. maxima*) in the Torres Strait and farther west—the large *Trochus* shell from which pearl buttons are made, edible oysters of various kinds, bêche-de-mer (Holothurians), both edible and tortoise-shell turtles, dugong, many kinds of fish, while sponges of some commercial value are present. In its capacity as a breakwater the Barrier Reef has gained for the enclosed steamer channel the title of Australia's Grand Canal, but it is a canal full of dangers from reefs and, in the summer, from cyclones, and loss from shipwreck forms a very serious item in the debit account.

The Discovery of a Second Braincase of *Sinanthropus*.

By Prof. G. ELLIOT SMITH, F.R.S.

AT a meeting of the Geological Society of China in the last week of July, Prof. Davidson Black announced the discovery of another skull of Peking man.

In NATURE of Mar. 22, 1930 (p. 448), an account was given of the discovery of a series of remains of *Sinanthropus* culminating in the recovery of an almost complete braincase by Mr. W. C. Pei on Dec. 2, 1929, while clearing a sheltered recess of the main deposit at Chou Kou Tien. Some days (Oct. 28) before this skull was found, five human teeth were recovered from a spot higher up in the shaft (locus *D* of the excavators' report), where they were associated with the skull of a large deer and some pieces of fossilised bone and blocks of stone, which were brought to the laboratory in Peking for examination.

This material was 'developed' during the third week in June by the technical assistants working under Prof. Davidson Black's supervision, and he found that there were enough fragments, which fitted together, to form the greater part of another uncrushed skull of *Sinanthropus*. He waited until the return to Peking of Dr. Wong (Wong Wen Hao), the Director of the Survey, before making the public announcement of his important discovery.

For reasons which are not yet clear to those who have not seen the actual specimens, Prof. Davidson Black regards the skull found on Dec. 2, 1929, as that of a young woman, and the calvaria the discovery of which is now reported is in his opinion that of a young adult male. It conforms to the same general type as the skull previously found, and its proportions are similar. But the braincase is not so thick and the frontal eminences not so pronounced. The most interesting new fact revealed in this

discovery is the nature of the root of the nose, which is broad and flat and quite unlike that of Piltdown man.

The newly discovered skull was found in association with a number of teeth which can be assumed to have belonged to the same individual. This fact adds to the interest of two mandibles found in 1928 in association with the crushed parts of the respective braincases.

The remains of four skulls of *Sinanthropus* and teeth of at least six other individuals have so far been found. Thus there is available for study in China a much richer material of early Pleistocene man than the fragments of the individual specimens of *Pithecanthropus* and *Eoanthropus* provide. Moreover, the geological age of the Chinese fossils can be established with more certainty than that of the other two primitive genera, which are assumed to be roughly contemporaneous.

The fossils from Java and Sussex were found in gravels, where they had been deposited by running water. Although there is little doubt which of the heterogeneous fossils found in these gravels were contemporaneous with the human remains, in the case of the men of Peking, who left their bones in the cave where they lived, there is less room for doubt that the bones of animals deposited alongside them provide more certain data for the estimation of their geological age. Thus the claim made by Père Teilhard de Chardin and Dr. C. C. Young that *Sinanthropus* lived in Lower Pleistocene times rests upon a surer foundation than the similar claims that have been made in the cases of *Pithecanthropus* and *Eoanthropus*.

Further, the conditions under which the discoveries are being made at Chou Kou Tien hold out a greater promise of further evidence than in the cases where the fossils have been scattered by running water. Thus a series of fragments have already been recovered every autumn since the type tooth was recovered in 1927, and it is not unreasonable to expect that much more still remains to be found in this cave, and possibly in other fossil beds in the neighbourhood. So far no worked tools have been found in the cave; but if such should be recovered, their association with the human remains will be less uncertain than in the case of the other Pleistocene men's implements.

For these reasons, in addition to the intrinsic interest and morphological significance of the skulls of *Sinanthropus*, the discoveries in China have an importance which is unique. It is a matter for congratulation that the investigation of this site should have fallen into such competent hands and that ample facilities and skilled assistance should be available for the work, which is being conducted with great thoroughness and insight.

News and Views.

PROF. ELLIOT SMITH's announcement in another column of this issue that Dr. Davidson Black has reconstructed still another skull of Peking man from material obtained from the now famous cave of Chou Kou Tien is assuredly welcome though perhaps not entirely surprising. Four skulls and teeth belonging to probably six individuals have now been obtained from this source, and it is therefore evident that the fortunate explorers have lighted upon what must have been the final resting place and perhaps the home of a family group or horde of this type of early man. So far, no implements have been found which would determine the cultural horizon of Peking man, but the conditions of discovery are such as to afford grounds for hope. It is at any rate fortunate that the association of the remains with fossilised bones of animals assigned with some confidence to the Lower Pleistocene appears to place the date beyond question. Dr. Davidson Black has pronounced his latest skull to be that of a young adult male, while that found in December last is said to be that of a young woman. Comparative study of the two will no doubt be fruitful of results. A first inspection of the new skull has already yielded a new character of the nose in which it presents a marked difference from the Piltdown skull. A more detailed examination of the two skulls than is yet possible will be necessary before it can be determined what are the precise relationships of Peking man and other early types. It is already clear, however, that these remains will make possible a further advance in the reconstruction of man's ancestral forms. Prof. Elliot Smith is sailing for China on Aug. 14, and in this connexion the results of his personal examination of the material will be awaited with the keenest interest.

IN the interesting little church at Longfield, Kent, close to Fawkham Station, is to be seen the memorial window erected by some members of the University of Cambridge to the memory of Dr. Thomas Plume, the founder of the Plumian professorship of astronomy, of which Sir A. S. Eddington is the present holder. Though never rector of Longfield, Plume for many years lived at Longfield Court, just behind the church, and he died there on Nov. 24, 1704. At his death Plume was seventy-four years of age, having been born just three hundred years ago, in the summer of 1630. The exact date of his birth does not appear to be known, but he was baptised on Aug. 18, 1630, in All Saints' Church, Malden, Essex, of which place his father was an alderman. Educated first at Chelmsford Grammar School, Plume entered Christ's College, Cambridge, and at the age of nineteen took the degree of M.A. Entering the Church, in 1658 he was made vicar of Greenwich, a living then in the gift of Richard Cromwell, and both Pepys and Evelyn speak of his excellent preaching. This important living he held for the remainder of his life, but from 1679 onward was also Archdeacon of Rochester.

LIKE Lucas and Lowndes, the founders of two other famous professorships at Cambridge, Plume did not add to mathematical or astronomical knowledge, but he lived in an age when among men of education

some acquaintance with science was considered a desirable acquisition. Moreover, as vicar of Greenwich when the Royal Observatory was built, he became known to Flamsteed, and it is said that on Flamsteed's recommendation he read Huygens' "Cosmotheoros". It is also said it was the perusal of this work which induced him to leave a part of his fortune to found a professorship and erect an observatory at Cambridge. Newton and Flamsteed were both connected with the arrangements made to carry out Plume's wishes, and when Roger Cotes was appointed to the Plumian professorship in 1707, the King's gate of Trinity College was appropriated to his use, while the observatory erected over the gateway was described by Bentley as "the commodiousest building for that use in Christendom". In spite of the provision of the observatory, little was accomplished in the eighteenth century, and a report of 1792 said that "the professor had neither occupied the said rooms and leads nor fulfilled the conditions for at least fifty years". Instruments and observatory alike had fallen into disrepair, and a few years later the observatory was demolished. A new observatory was built in 1822; with the appointment of Airy as Plumian professor in 1828, astronomical studies at Cambridge were pursued with greater energy, and under his successors much has been done to add prestige to the chair which perpetuates the name of its generous and enlightened founder.

THE Earl of Harewood performed a useful service to the agricultural community by initiating the discussion in the House of Lords on July 22 on the position of the Royal Veterinary College, Camden Town. He pointed out that the position of the College was so desperate that unless further substantial guarantees of capital and income from Government and private sources were immediately forthcoming, the governors would have no alternative but to give notice of their intention to close and to refuse to accept any new students. The annual deficit of the College is a diminishing one owing to the fact that students' fees are increasing year by year and private subscriptions are also bringing in a larger yearly income; but the College buildings are in an irreparable state of disrepair and their entire reconstruction is an imperative necessity. An appeal for the necessary funds to make the College worthy of its cause was made three years ago, but of the £350,000 needed only £30,000 had been raised from those who have most to gain from the maintenance of the supply of adequately trained veterinarians, namely, the great breeders of pedigree cattle, small farmers, sportsmen, and animal lovers generally. The governors of the College had asked the Ministry of Agriculture and Fisheries for advice and a Departmental Committee was appointed. This Committee reported a year ago and recommended that the governors should purchase for £20,000 the freehold of the land in Camden Town from the Ecclesiastical Commissioners, spend £280,000 on new buildings, provide £25,000 for a research laboratory outside London and affiliated to the College, and guarantee an income of £21,000. No reference was made in this report to the financial help the Government might be expected to give, although the offer of £100,000 made by the Government in 1918 presumably still held good, although this offer had been contingent upon the College removing to Cambridge.

A FURTHER appeal for financial assistance was recently made to the Government by the governors of the College, whereupon a further Departmental Committee was appointed which modified the above proposals by suggesting that the purchase of the freehold was unnecessary, that £250,000 instead of £280,000 be spent on new buildings, towards which the Government would be prepared to contribute £70,000 in addition to pound for pound of the subscriptions raised from private sources. Further, the Government was prepared to make a final grant of £50,000 when the sum collected by the governors from all sources had reached £200,000. This offer Lord Harewood, Lord Ernle, and others characterised as not sufficient to justify the governors committing themselves to keep the College open. Lord Ernle suggested that the British Government lagged behind those of other countries in its encouragement of veterinary education, citing the case of Germany, which provides £280,000 a year for this purpose. After Lord Phillimore had pointed out that he had been asked, as the chairman of a veterinary subcommittee on the 'pig', to emphasise the need for more attention to be given by pig-breeders to research, but that it was useless for him to do so unless there were enough veterinary experts adequately trained to make use of the results of such research, Lord De La Warr, on behalf of the Government, invited to a conference those interested in veterinary education and the future of the Royal Veterinary College, in order that the governors of that institution might reconsider the position. Since then, a further powerfully worded appeal has been made to the Government by Sir Merrik Burrell, chairman of the governors of the College, in a letter to the *Times*. Apparently these appeals have not been fruitless, for Lord Harewood, in his address to the eleventh International Veterinary Congress, which he opened on Aug. 4, expressed the hope that the position of the Royal Veterinary College would soon be remedied.

A RECENT Order in Council directs that the Lord President of the Council (Lord Parmoor), the Minister of Agriculture and Fisheries (Dr. Addison), the Home Secretary (Mr. Clynes), the Secretary of State for Scotland (Mr. W. Adamson), and the President of the Board of Education (Sir Charles Trevelyan) shall be a Committee of the Privy Council for the organisation and development of agricultural research. It is also ordered that during His Majesty's pleasure the Lord President of the Council shall be the chairman, and the Minister of Agriculture and Fisheries vice-chairman of the Committee. No information is vouchsafed regarding the relationships between this new body and the Development Commission, the Agricultural Research Council, and the Empire Marketing Board, all of which are concerned with the promotion of agricultural and fisheries research. Presumably this new committee, the personnel of which is exclusively political, will undertake the task of co-

ordinating the efforts of these other important bodies, although the further announcement made in the House of Commons on Aug. 1 by the Chancellor of the Exchequer (Mr. Snowden) creates the impression that it will be concerned mainly with the appointment of *ad hoc* committees for advising the Government on schemes for the prosecution of research on urgent problems confronting the agricultural community. It is to be hoped that the Government will make a further announcement or issue an explanatory memorandum defining more precisely the functions of this new Committee of the Privy Council, and why it differs so radically in constitution from those already in existence for the prosecution of medical research and scientific and industrial research.

THE visit of H.R.H. the Duke of York on July 30 to the works of the British Aluminium Company at Fort William, N.B., may be said to mark in a quasi-formal way the inauguration of the very notable hydro-electric undertaking known as the Lochaber Power Scheme, which has been promoted by the company for the purpose of supplying power to its factory for the production of aluminium. The portion of the undertaking which is so far completed has been in operation for the past few months, but the plant at present installed, with a capacity of 50,000 horse power, represents only about half the energy available when the sources of supply are developed to their full extent. As it stands, however, the installation is of a remarkable character, being the most important of its kind in Great Britain and ranking high among similar undertakings throughout the world. The scheme is designed to utilise the impounded water contained in Loch Laggan and Loch Treig, at a height of about 800 ft. above sea level, to drive turbines in the power house at Fort William a few feet above the same datum. In order to connect the two lochs and convey the water therefrom to Fort William, tunnelling through the intervening mountain rock is necessary for an aggregate distance of 19 miles, and of this, a length of 15 miles, constituting the portion connecting Loch Treig with the Power House, has been completed. The Lochaber Tunnel, as it is designated, is one of the longest tunnels in the world, and far longer than any other in Great Britain. Its nearest rival on the Continent is the Simplon Tunnel between Switzerland and Italy, which is 12¼ miles in length. The Shandaken Tunnel for the water supply of New York is slightly more than 18 miles long, but in cross sectional area it is less than the Lochaber Tunnel, which is approximately circular and 15 ft. in diameter. The Power House at Fort William contains, at present, five main turbo-generator units each of 10,000 horse power. The inception of the Lochaber scheme is due to Mr. Murray Morrison, director and general manager of the British Aluminium Company, which in 1921 obtained powers under the Lochaber Water Power Act for its realisation. The engineers are Messrs. Meik and Halcrow of Westminster.

A CEREMONY of striking appropriateness took place at Inchnadamph, in the wilds of the north-western highlands of Scotland, on July 25, when a memorial to Drs. B. N. Peach and John Horne was unveiled by Sir John Flett. Mr. H. M. Cadell of Grange, who presided over a company which included many well-known Scottish scientific workers, recalled the days when with Peach and Horne he commenced the final survey of the much discussed structure of the Western Highlands, and gave a summary of the dispute which had centred upon that complicated region, and had at length been settled through the labours of his former colleagues. In dedicating the memorial, Sir John Flett described its site as properly selected in the centre of a remarkable area to which the discoveries and interpretations of Peach and Horne had given world-wide fame, a temple of geology to which geologists from all parts of the earth made pilgrimage. He paid a warm tribute to the work of his friends, to their spirit of co-operation and goodwill, and to the single-mindedness of their scientific endeavours. The memorial, a massive pillar of stone set on a height overlooking Loch Assynt, carries a bronze tablet with the inscription : "To Ben N. Peach and John Horne, who played the foremost part in unravelling the geological structure of the North-West Highlands, 1883–1897 : An international tribute. Erected 1930."

UNDER the title of "The Organisation of Mosquito Control Work" Mr. John F. Marshall, Director of the British Mosquito Control Institute, Hayling Island, Hants, has issued a useful practical pamphlet. Its contents formed his presidential address in the Zoology Section of the South-eastern Union of Scientific Societies at the Portsmouth Congress held in May last. The object of this pamphlet is to describe, in simple language, the best methods of suppression of mosquitoes in England. It is pointed out that these insects must be dealt with during the larval or pupal stages of their existence, and that the most satisfactory method is to do away with the water in which such stages are passed. This may be a simple matter in so far as water butts or small ponds are concerned. With ditches, large pools, or marshes, drainage is required, but this procedure, for various reasons, is often quite impracticable ; in such cases the problem is best dealt with by covering the surface of the water with oil, or by mixing chemicals with the water so as to poison the larvæ. In the case of ornamental ponds or lakes, fish, water bugs, and various other creatures which devour the eggs or larvæ are to be encouraged, and the addition of oil or chemicals to the water is then undesirable or harmful.

MR. MARSHALL gives a list of the British mosquitoes grouped according to their habitats or, in other words, according to the nature of the environment in which each species lays its eggs and where, in consequence, its larvæ are to be found. The first step to be taken is to find out what species are present, and when this has been done the anti-larval campaign is simplified. It then becomes possible to seek out their breeding places and take necessary measures at the right time. Indiscriminate oiling of all and sundry collections of water is wasteful and of little use. As an example it is mentioned that at a children's hospital where sleeping out of doors was part of the treatment, mosquitoes rendered this procedure impossible at certain times of the year. All tanks and butts were regularly sprayed

with paraffin in the hospital grounds, without result. Afterwards specimens of the offending insects were sent to the Mosquito Institute, and the species was found to be *Aedes punctor*, which breeds chiefly in pine woods. A number of small pools occurred in the neighbouring woods, and since these have been abolished further annoyance from mosquitoes has been avoided. Methods of identifying mosquitoes either from the larvæ or adults are briefly described. It is further pointed out that adequate control work needs the services of an inspector who, after identifying the species concerned, examines their breeding places and advises whether the collections of infested water shall be oiled, poisoned, or abolished. The pamphlet, it may be added, can be obtained at the British Mosquito Control Institute, price 9*d.*

It is now generally admitted that the radiation of the sun varies when periods of a month or more are considered, and the comparison of data from different stations is justifying Dr. C. G. Abbot's view that there also exist variations from day to day. In a paper entitled "The Atmosphere and the Sun", published as No. 7 of vol. 82 of the Smithsonian Miscellaneous Collections, Mr. Clayton sets out his grounds for adopting two further conclusions, namely, that these solar variations are periodic, and that they provoke definite reactions in terrestrial weather, which behave in a complicated but still predictable manner. The first element of weather to be affected is naturally temperature, but this is complicated by changes of cloudiness, and for the most part the author deals with waves of pressure. As a result of a somewhat superficial discussion, he concludes that there are systematic differences between the pressure distribution over the northern hemisphere associated with high solar radiation and that associated with low radiation, the effects changing from one latitude to another, from season to season, and from land to sea. The differences found are small, however, and as no criteria of reality are given, it is impossible to tell to what extent they are accidental. The disturbances once set up travel like ordinary barometric systems, and since the solar changes which cause them are periodic, the results are series of supposedly regular waves of pressure in all parts of the world. Mr. Clayton thinks that when the sudden changes of phase and amplitude which mar these 'cycles' are understood their use will supplant all other methods of forecasting, but one fears that this day is very distant. Nevertheless, this is an interesting study, which opens out a distinctly promising line of investigation.

Further light has been thrown on the development of the circle in Britain by recent excavations carried out by Captain and Mrs. Cunnington on a site known as "The Sanctuary", on Overton Hill, between Marlborough and Devizes. Stukely records that the double circle on Overton Hill was destroyed in 1724; but nothing was known of it beyond the fact that it had consisted of two circles of sarcens, until Captain and Mrs. Cunnington succeeded in locating its position by ingeniously making use of a clue afforded by Stukely's theory that Avebury and "The Sanctuary" were connected with serpent worship, and that Avebury was the body and Overbury the head of the serpent. An account of their excavations was presented at the annual meeting of the Wiltshire Archæological Society, of which a report appeared in the *Times* of Aug. 1. The excavations revealed not only the position of the stones of the double circle, but also holes in which had stood wooden posts forming six rings concentric with the stone circles. This site, being so closely connected with Avebury, thus links up the latter with "Woodhenge" (Durrington Walls), the forerunner of Stonehenge. One burial only was found. With this was associated a small vessel of 'beaker' type. It is, therefore, suggested that the original construction took place in the early Bronze Age, and that when later—still in the early Bronze Age—Avebury was constructed and the two sites connected by an avenue of standing stones, the wooden posts of "The Sanctuary" were replaced by two circles of standing stones. Captain and Mrs. Cunnington have added further to their great services to British archæology by purchasing the site on Overton Hill, and they now propose to reconstruct the wooden and stone circles by erecting concrete pillars as they have already done on their previously purchased site of Woodhenge.

In an article published in the *Times* for July 31, Dr. C. Davison gives a new estimate of the average annual loss of life by earthquakes. During the last century covered by Milne's great catalogue of destructive earthquakes (1800–99), there are recorded by him 364 earthquakes of the highest degree of intensity and 510 of the second degree those of the lowest degree do not contribute sensibly to the loss of life. From 1601 to 1900, the number of persons killed by the most destructive earthquakes in Italy was 4222 per earthquake, and by those of the second degree 8·3, so that, if the same rates governed all earthquakes, the mean annual loss for the whole world would be 15,410. The stronger Japanese earthquakes of the eighteenth and nineteenth centuries give an average of 3892 deaths per earthquake or of 14,169 every year for the whole world. Dr. Davison thus concludes that, on an average, fourteen or fifteen thousand persons are killed by earthquakes every year, a number that is much less than the number killed by motors annually in the United States, and not much more than twice the number killed in Great Britain.

The three expeditions which Dr. Johs. Schmidt describes in the "Introduction to the Oceanographical Reports" (Danish *Dana* Expeditions, 1920–22, Copenhagen, 1929) were the post-War continuation of the researches on the development and breeding of the European eel begun in 1903 with the *Thor* and *Margrethe*. As soon as possible after the War, three cruises were made to the Sargasso Sea, two of which were undertaken in the auxiliary schooner *Dana I.*, and were confined mainly to the study of pelagic fauna. The third and most extensive voyage was made with the Royal Danish R.S. *Dana*, a steam trawler of the Lord Mersey class, adapted for marine research. The programme on this occasion was

augmented by physical observations, notably hydrographic sections across the North Equatorial Current and the Gulf Stream. Some of the results then obtained in the Gibraltar straits were published in NATURE of Jan. 12, 1922. A seasonal periodicity in the biological phenomena of the Sargasso and Caribbean Seas was demonstrated, and a number of very young larvæ of the European eel (and possibly the ova also) were taken in the Sargasso Sea at between 200 and 500 m. depth, thus completing the series of developmental stages. Dr. Schmidt and his colleagues have now returned from a two years' expedition, the most ambitious so far undertaken with the *Dana*, to the Pacific Ocean, where the breeding habits of the eels common to those waters have been found similar, though with less extensive migrations, to those of the Atlantic forms.

The announcement has just been made that the whole human population of St. Kilda is to be evacuated from the island in September next, 27 to Mull, 8 to Skye, 1 each to Glasgow and Inverness; and thereafter St. Kilda will take its place with North Rona and others of the Scottish isles, which, once inhabited, have become derelict. In this connexion a short article in the *Scottish Naturalist* (p. 69), by Dr. James Ritchie, discusses some of the unique features of the fauna of St. Kilda, its indigenous wren, field-mouse, and house-mouse, and its Soay sheep, the most primitive of surviving races of domesticated sheep. He also endeavours to show how the change in the feeding habits of the human population when it was brought in regular contact with mainland civilisation, first in 1877, affected the numbers of fulmar petrels breeding on the islands. This was ultimately responsible to a great extent for the extraordinary exodus of fulmars which has resulted in the colonising of many of the islands and of the mainland cliffs so far south as Flamborough Head.

SEARCHLIGHTS are usually associated with naval and military operations. It is not generally realised that there is a great demand for them for commercial purposes, such as canal lighting, the flood lighting of buildings, and cinema studios. There are manufacturing firms which are mainly if not solely engaged in making searchlights and projectors of all types and sizes. In the *British Engineers' Home and Export Journal* for July, a description is given of very large searchlights manufactured by the London Electric Firm, Croydon, for a continental government. The candle power of each searchlight was rated by the National Physical Laboratory as 3500 million. This means that if the horizon were sufficiently far away and meteorological conditions were suitable, the lights would be visible for hundreds of miles. These lights are to be used for frontier defence, and although they are seven feet in diameter can easily be controlled electrically by an operator at any distance away. By means of a signalling shutter mechanism, morse signals can be sent by the beam. The same firm has also made searchlights for use in navigating the Suez Canal at night. They send out a divided beam illuminating each side of the canal and leaving a dark patch in the centre so as to avoid dazzling the eyes of the pilot of a ship coming in the opposite direction. The electric carbons burn for 6½ hours, thus obviating the necessity of trimming the lamp when in the canal. The lamps used in cinema studios give either 'spot' or wide angle lighting. Searchlights are also used in aerodromes for fog penetration and for 'writing' on the clouds.

THE "Bulletin de l'Union des Sociétés Savantes Polonaises de Léopol (Lwow)" for 1927–1928 records the successful attempt of a local bureau to bring together the work of the local branches of Polish learned societies. It has been edited by Prof. Sigmond Czerny, (15 rue Tarnowskiego) of the University of Léopol. One hundred pages comprise reports from some three dozen societies. Contacts are maintained with a wider world through Paris and America, by exchanges of periodicals and by representatives to international congresses. The interests of the bureau include much recording of unhappy histories, some care of orphans and widows, cemeteries ancient and modern, excursions to historic monuments, the collection of books and archives into museums and libraries, archæology, jubilees and centenaries of brighter moments, folklore, regional survey, heraldry, classical studies, school geography, local natural history, Slavonic philology and ethnology, the glacial epoch, reorganisation of finances, economic discussions in collaboration with the ministry, publications in Polish with abstracts in French, English, Latin or German, international law in relation to Chorzow and Dantzig, echoes of western science, some medical and mathematical research. The general picture presented by these reports is that of a struggle out of confusion and towards the light. The particular device of a local bureau of local branches of national societies is one that might be useful elsewhere, if only as a clearing-house for harmonising time-tables.

IT is announced in the *Journal of the Society for the Preservation of the Fauna of the Empire* for 1930 that in future the *Journal* will be issued more frequently, and an appeal is made to members for articles on any matter relative to the conservation of wild life. The present number, apart from recording the activities of the Society during the past year, contains some interesting extracts from faunal reports dealing with various parts of the Empire. In Uganda the "astonishingly small number of young gorillas in the troops" is attributed to the attacks of leopards; in Victoria it has been found that the complaints of fishermen regarding the serious menace of seals to fisheries have not been substantiated; and the success of the inoculation of domestic stock in Southern Rhodesia against trypanosomiasis is a matter of first-rate importance to the wild life of the country, as well as to the farmer.

THE Arctic archipelago of Franz Josef Land, now within the realm of Soviet jurisdiction, is seldom visited except by Norwegian walrus and bear hunters, although the scientific knowledge of the group is due chiefly to British, Austrian, Italian, and American expeditions. It is useful to have a summary of what

is known. This has been prepared by Dr. G. Horn and appears as No. 29 of *Skrifter om Svalbard og Ishavet* (Oslo, 1929). The paper includes a fairly complete bibliography and a sketch map showing the routes of the chief expeditions. Dr. Horn antedates the discovery which is generally attributed to J. Payer in 1873 to two Norwegian sealers in 1865. He cannot, however, adduce any written evidence of the discovery of North-East Spitsbergen in that year or proof that the land called by this name was Franz Josef Land, although the identity is not impossible.

THE Medical Research Council has appointed Major A. G. Church, M.P., Col. F. E. Fremantle, M.P., and Sir John H. Parsons to be members of its Industrial Health Research Board.

SIR CHARLES MARTIN, who will shortly retire from the directorship of the Lister Institute, has accepted a pressing invitation from the Commonwealth Council for Scientific and Industrial Research to take charge of its Division of Animal Nutrition for at least two years. This Division was established in 1927 under the late Prof. T. Brailsford Robertson, and has been concerned mainly with problems of wool production. The central laboratory is in the grounds of the University of Adelaide, while there are eight field stations scattered over the more important pastoral areas. Sir Charles Martin will probably leave England towards the end of December and will break his journey at South Africa in order to visit the veterinary research station at Onderstepoort.

THE thirty-sixth annual report of the governing body of the Lister Institute of Preventive Medicine has recently been issued. It contains a brief but useful and interesting survey of the researches which are, or have been, in progress during the year in the various departments of the Institute. Sir Charles Martin, the Director, and Prof. Arthur Harden will be retiring under the age limit towards the end of this year, and the governing body has appointed Prof. J. C. G. Ledingham and Dr. R. Robison to fill the vacancies thus created, the appointments to date from Jan. 1 next.

THE fact that cancer occurs with some frequency in human beings, for example, mule-spinner operatives, as a result of contact with lubricating mineral oils, has caused some alarm among those taking mineral oils for medicinal purposes. We learn from a recent *Science News Bulletin* (Science Service, Washington, D.C.) that Dr. Francis Wood of the Institute for Cancer Research, Columbia University, has tested several makes of medical mineral oil for the presence of carcinogenic properties upon mice, of a strain known to be liable to the development of cancer, by painting the skin and by internal administration. The results were negative, so that mineral oils of the type used for medical treatment may be regarded as being free from any risk of producing cancer.

CATALOGUE No. 13 of second-hand books (543 in number), on mammals, birds, insects, shells, etc., geology, fossil plants, botany, and horticulture, has just been issued by Mr. J. H. Knowles, 92 Solon Road, S.W.2.

THE Cambridge University Press announces the publication in September of vol. 3, in 2 parts, of Prof. Karl Pearson's "Life, Letters and Labours of Francis Galton"; IIIA will deal with "Correlation, Personal Identification and Eugenics", and IIIB with "Characterisation, especially by Letters".

THE latest catalogue (No. 528) of Messrs Francis Edwards, Ltd., 83 High Street, Marylebone, W.1, deals with books, pamphlets, engravings, maps, and original drawings relating to Latin America, the British colonies of the Falkland Islands, Honduras, and Guiana offered for sale by the firm. The catalogue, which is an interesting one, contains upwards of a thousand items.

UNDER the title of "Principles and Practice of Geophysical Prospecting", and edited by Mr. A. Broughton Edge and Prof. T. H. Laby, the Report of the Imperial Geophysical Experimental Survey will be published by the Cambridge University Press in December. The work is in two parts, one dealing with the actual field results obtained in Australia, and the other giving a more theoretical discussion of the subject, which, is is hoped, will be of service to students of practical geophysics in English-speaking countries.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant at the Road Experimental Station of the Ministry of Transport Roads Department at Harmondsworth, near Colnbrook, Middlesex—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1 (Aug. 11). An engineer in the Midland Division of the Ministry of Transport Roads Department—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1 (Aug. 11). An assistant lecturer in agricultural biology (bacteriology, botany and zoology), at the East Anglian Institute of Agriculture, Chelmsford—The Clerk of the County Council, Shire Hall, Chelmsford (Aug. 12). A lecturer in engineering at the Plymouth and Devonport Technical College—The Secretary for Education, Rowe Street, Plymouth (Aug. 16). Four technical assistants (either sex) at the Manchester Royal Infirmary, for clinical laboratory work—The Chairman of the Medical Board, Royal Infirmary, Manchester (Aug. 16). A horticultural instructor for Norfolk County Council—The Horticultural Superintendent, 30 Cattle Market Street, Norwich (Aug. 21). A professor of physics, and head of the department, in the Muslim University, Aligarh, U.P., India—Vice-Chancellor S. R. Masood, Box 24, c/o NATURE Office (Aug, 23). A general secretary of the Eugenics Society—The Honorary Secretary, Eugenics Society, 20 Grosvenor Gardens, S.W.1 (Sept. 15). A Norwegian professor of marine engineering in the Technical University of Norway—Kirke-og Undervisningsdepartementet, Oslo, Norway (Oct. 1). A medico-physicist to organise and take charge of the Sheffield National Radium Centre—The Secretary, Royal Infirmary, Sheffield.

Research Items.

Composition of Ancient Glassware.—Most people are familiar with Pliny's story of the discovery of glass, but modern researches have shown that it must be regarded as apocryphal, for glass-making has been found to antedate the Phœnicians by many centuries. Glass beads, for example, are plentiful in the excavations of a cemetery of the Third Dynasty of Ur (2450 B.C.). In a discussion of ancient glassware, G. M. Morey shows that the oldest analysed glasses, including specimens from the tombs at Thebes dating from 1500 B.C., have much the same composition as the common glass of to-day (*Art and Archæology*, Dec. 1929). All have silica, lime, and soda as their essential ingredients, and the composition range is remarkably narrow. Only three types of mixtures are known which possess the glass-making property of passing through their freezing points without transformation to crystalline solids; these are characterised by the presence of phosphates, borates, or silicates. Moreover, only the latter can resist successfully the attack of atmospheric agencies. The reason for the restricted composition range is that, of all possible mixtures, only those near the composition represented by $Na_2O \cdot 3CaO \cdot 6SiO_2$ can give a glass with the desired properties. With variation in silica either way the melting-temperature rises and the resulting 'glass' is opaque. Too much lime also gives opaque material; too little makes a readily weathered glass. With too much soda the resulting glass is not durable. In primitive glass-making a low melting-temperature was an important feature and in consequence the older glasses carry more alkali than would to-day be considered good practice.

Transformative Protective Coloration.—Complaint has often been made of the assumptions on which cases of protective coloration are founded, and this complaint would appear to be based on good grounds in the case of the so-called 'transformative protective coloration', described by Karny, by which he means the capacity of an insect or other animal to transform its juvenile protective coloration to a further and different protective coloration in adult life. A searching criticism is made by F. Heikertinger (*Biol. Zentralbl.*, vol. 50, p. 193, 1930) of the work of Karny on transformative protective coloration in the Bornean species of *Asthates*, one of the Longicorn beetles. Karny, he says, founds his work on the uncritical and hypothetical work of Shelford, curator of the Sarawak Museum, on the mimetic insects of Borneo. The latter regards the case of the Asthates as typical protective coloration, the models belonging to the sub-family Galerucinae. Shelford writes with no positive knowledge as to whether Asthates is tasteful or repulsive to its enemies, ignoring the modern biological requirements essential to a discussion of the question, namely, a really exact knowledge of the perceptions, tastes, and food of the enemies against which the animals are supposed to be protected. On the other hand, Heikertinger now contributes practical or positive data relating to the food of local birds, whence it appears that both models and mimics are devoured with equal impartiality. Karny's new case of 'transformative' coloration has therefore no scientific ground, and the author pleads for a more critical treatment of the whole ecological problem of so-called mimicry.

Arctic Birds of Historic Interest.—In the last two numbers of the *Scottish Naturalist*, Admiral J. H. Stenhouse continues his accounts of the birds of historic interest in the Royal Scottish Museum. In the second paper of the series he discusses the birds of Parry's voyages: from the second voyage (1821–23) thirty-five specimens, representing nineteen species, survive, from the third voyage (1824–25) ten, and from the fourth voyage (1827) twelve. The third paper deals with the birds of Franklin's Overland Expeditions, of which the second is best represented by fifty-eight birds, some being type specimens described by Swainston and Sir John Richardson, and the *Tetrao franklinii* of Douglas.

Chromosome Cycle in the Actinomyxidia.—In the epithelium of the intestine of *Tubifex tubifex*, Naville (*Quart. Jour. Micro. Sci.*, May 1930) discovered a new species and genus of an Actinomyxidian which he has named *Guyénotia spherulosa*. It is characterised *inter alia* by the possession of a spheroidal spore with three suture lines 120° apart, three polar capsules, and three digitiform appendages. The female germ line shows a marked meiotic inertia as compared with the male. Each shows three successive divisions in the formation of the gamete; the first is homotypic with four diploid chromosomes; the second is heterotypic reducing the four to two diploid chromosomes; and the third again homotypic. Fertilisation is accompanied by a restoration of the diploid number. The formation of the spore nuclei is somewhat like that in *Triactinomyxon legeri*, but residual nuclei are not formed. It is claimed that the results obtained are homologous with those found by the author in the Myxosporidia. Sex differentiation is more precocious in the Actinomyxidia and leads to the immediate formation of male and female germ lines. It has been shown in the Myxosporidia that increasing precocity in sex differentiation gradually leads to a dioecious condition, although this does not seem to have occured in the Actinomyxidia.

History of the Rhône Delta.—In the *Quart. Jour. Geol. Soc.*, vol. 86, pp. 64-93, 1930, Mr. R. D. Oldham presents the results of his researches into the historic changes of level in the delta of the Rhône. At the opening of the Pleistocene period, the whole area was covered by a deposit of gravel and well-rounded boulders. A period of subsidence then set in and an alluvial delta was built up, the lower part being arenaceous and the upper of finer sand and silt. A period of uplift followed and the land rose not less than 14 metres above the level to which it had previously sunk. The settlements and structures of the Romans were erected on the weathered surface of erosion then developed, but before the Roman occupation a period of intermittent subsidence had already begun. One of the episodes of movement probably occurred between the years 1000 and 1500 B.C. The next change took place in the eighth and ninth centuries A.D. and involved a downward displacement of 5 metres. Lastly, there was a fresh movement of subsidence of about a metre which was practically completed during the latter half of the eighteenth century. Thus, at the present time the total amount of subsidence has reached some 10 metres, so that the land still stands about 4 metres above the lowest level reached before the period of 14 metres uplift set in (see also NATURE, April 19, p. 601).

River Flow Records.—Two Reports on River Flow in the rivers Garry and Morriston, in the Ness Basin, Inverness-shire, which have been received from the offices of River Flow Records (Parliament Mansions, Victoria Street, S.W.1), continue for a further period of three months (that is, from October to December 1929) the observations which were initiated as a private enterprise by Capt. W. N. McClean in the

earlier part of the year. The first instalment of data for the period July to September 1929 was the subject of notice in NATURE of Mar. 1 last; and while this second series is unquestionably helpful in extending the record of exact measurement, and will on that account be cordially welcomed by all who are interested in river development work, it suffers from the disability of its predecessor in that obviously the observations have not yet been carried sufficiently far to render them useful to a higher degree than that of assisting to arrive at approximations of flow of a very general character. Time and continuity will, of course, remedy this deficiency. The fresh records during the three closing months of 1929 are confined to rainfall gauge and water level readings, with calculated deductions therefrom, and no further actual measurements of river flow were made, the hope being expressed in the reports that those may be resumed during the year 1930. The two pamphlets will be valuable for filing and reference. They are further of serviceable interest in indicating how records of river flow may be computed and compiled in an organised manner under some general supervision by a staff of local helpers, aided by occasional expert survey work.

Changes of Rock Temperature.—In the *Proceedings* of the Royal Society of Edinburgh, vol. 50, pp. 153-165, R. W. Wrigley writes "On Changes of Rock Temperatures and Irregularities of the Earth's Rotation". The work is based on the long and unique series of rock temperatures at depths of about 6, 12, and 25 feet made at Calton Hill, Edinburgh, 1838-1876, 1880-1929. These were used by Forbes and Kelvin for the discussion of the downward conduction of heat from the earth's surface; they are here used in a search for any indication of variability in the supply of heat to the earth's crust from below. It is concluded that, when freed from the influence of surface changes, the thermometers show real and distinct fluctuations, accordant with one another, and attributable to deep-seated causes; confirmation of this view is obtained from Greenwich measures of the temperature at 25·6 ft. depth, for the period 1868-1910. The course of these temperature changes is then compared with the 'minor' fluctuations of the moon's motion, according to E. W. Brown; the correlation is thought to be "too close to be the result of mere coincidence", and it is sought to relate both phenomena to crustal movements.

Infra-Red Radiation.—A good survey of the properties and applications of near infra-red radiation, based on two lectures by H. D. Babcock, of the Mt. Wilson Observatory, is given in a *News Service Bulletin* recently issued by the Carnegie Institution of Washington. It appears that the recent developments in the technique of infra-red photography, which have already been of the greatest value in spectroscopy, have come largely from the needs of the motion-picture industry; a daylight photograph taken by infra-red light appears not unlike a night scene, as is shown very well by two mountain photographs in the *Bulletin*. The present limit of sensitivity is put at 11600 A. A remarkable infra-red photograph taken from an aeroplane at an altitude of 17,000 ft., which is also reproduced, shows distinctly the peak of Mt. Rainier (14,400 ft.) at a distance of 227 miles.

Spectroscopy of Soft X-rays.—A spectrograph for the analysis of soft X-rays is described by Prof. M. Siegbahn and T. Magnusson in the *Zeitschrift für Physik* for June 18. It employs a plane grating, ruled with about the same spacing as for optical work, but used at almost grazing incidence. The grating itself, which is ruled only for a width of from one to three millimetres, replaces one slit in the collimating system for the incident beam. The spectra are recorded photographically on ordinary plates. The preparation of the grating is carried out with a new machine, in which the ruling point is brought down so gently at the beginning of each line that the usual pitting of the blank at this point is completely eliminated, and special care is also taken to avoid irregularities elsewhere on the prepared surface. The instrument is designed for use in the difficult region between about 10 A. and 100 A., where neither crystal spectrometers nor the new concave grating vacuum spectrograph—also elaborated at Uppsala—can be applied satisfactorily, so that instruments of good resolving power are now available for the whole of the far ultra-violet and soft X-ray sections of the spectrum.

Tests of Creep Stress.—The June issue of the *Transactions of the Institute of Marine Engineers* contains a reprint of the paper read to the Institute by Mr. S. L. Archbutt, of the National Physical Laboratory, on recent metallurgical research in relation to marine engineering. The reprint is accompanied by a report of the discussion which followed. Restricting his review to work done during the last ten years, Mr. Archbutt dealt in turn with materials for use at high temperatures; light alloys; corrosion; nitrogen case-hardening, and a new cutting tool material. In the design of turbines, boilers, and internal combustion engines there is an ever-increasing demand for materials which will not deteriorate at high temperatures, and one of the most important requirements in this connexion is ability to withstand prolonged loading; as for example in the walls of a steam superheater tube or drum. Extraordinary interest had been aroused by the phenomenon of creep which can occur when material is stressed for a long time at high temperature, the study of which led to the introduction of the term limiting creep stress, which is the upper limit of stress which a material will withstand without ultimate failure. To investigate creep under load, test pieces are hung vertically between shackles and surrounded by an electrically heated furnace. The importance of this study of creep is shown by the fact that, starting in 1921 with four creep furnaces, the number at the National Physical Laboratory has now been increased to twenty-five or more to cope with demands for tests. The report of Mr. Archbutt's paper is accompanied by many illustrations, among which is a view of the creep stress laboratory at Teddington.

Damage by Lightning to Telephone Cables.—In the March number of the *Europäischer Fernsprechdienst*, a journal for European international communication, published in Berlin, there is an interesting account by R. Wicar of damage done by lightning to a telephone cable connected with the Budapest-Vienna line. The lightning struck a large and flourishing acacia tree and severed the trunk completely in a transverse direction. The photograph given shows that the upper portion was partially buried in the ground and was left standing vertically beside the stump of the tree, giving the impression that two trees had been involved. From the trunk the lightning made its way at a depth of about a yard under the surface to the long-distance telephone cable. The path of the lightning was plainly marked by a channel about two square centimetres in cross section and six yards long. Notwithstanding the heavy rain, the earth round the tree was almost as dry as dust. The cable was bent and flattened for a length of about two feet where the lightning entered it. About two yards farther on, the cable sheath had been opened up and

partially deflagrated. During the repair work, it was noticed that the lightning had travelled along the lead sheath for several miles. It is instructive to learn that the insulation of the telephone conductors nearest to the sheath was damaged and even at a distance of more than a mile from the point of entry many broken wires were located. Photographs are shown of the damage done to the cable. Within forty-eight hours of the occurrence, the cable was again working satisfactorily. In 1929, southern Europe had unusually violent thunderstorms.

Efficiency of Telephone Transmitters.—The efficiency of a telephone transmitter varies largely with the distance of the mouth from it and also with the angle at which the air waves impinge on the diaphragm. It is not generally realised, however, that the loss in output for increasing distance between mouth and mouthpiece is greater than that due to the reduction in the air pressure. This is due to the fact that the sensitivity of the carbon granules diminishes rapidly as the amplitude of the vibrations diminishes. In *Electrical Communication* for April, L. C. Pocock gives an interesting account of progress in subscribers' transmission apparatus. He points out that transmitters used in handsets are like other transmitters spoken into from various distances, but are unlike fixed transmitters as this variation is unavoidable. The person using the telephone places the receiver on his ear and the transmitter is then automatically located at some distance from the mouth which depends on the shape and size of the user's head. If the handset is made rather small, people with rather large heads are not able to get the mouthpiece opposite their mouths at all, and so generally place it right underneath their chin, where it gives very bad transmission. On the other hand, if the handset is made larger the transmission will be poor except for the small number of outsize type of users who, owing to the increased length, can bring the transmitter opposite the mouth. To get over this difficulty, the Bell Telephone Laboratories made measurements on the heads of more than four thousand people. The result enabled them to construct a handset which the great majority of people will be able to use with the transmitter in the proper position with regard to the mouth. A description is given in detail of the new modern headset for automatic telephony developed by the International Telephone and Telegraph Corporation. The articulation gain with this instrument over the ordinary fixed set is about fifteen per cent.

Measurement of Interfacial Tension.—The previous measurements of surface tension by determining the pull necessary to detach a ring from the surface of a liquid have given results 30 per cent too high or too low in many cases, and in a paper in the May number of the *Journal of the American Chemical Society*, Harkins and Jordan show that this was due to the use of an inaccurate equation. The correct theory is given in a paper by Freud and Freud in the same journal, in which Laplace's differential equation is used to calculate the shapes of the surfaces upheld by rings. It is shown that the ring process could give results of the degree of accuracy of about 0·25 per cent, and is now an absolute method, since the surface tension can be determined by it without reference to any other method.

Distillation Products of Peat.—The commercial exploitation of peat, apart from its use as a crude fuel, remains as one of the challenging problems of applied chemistry of special interest to Ireland. J. T. Donnelly and J. Reilly have examined the carbonisation of peat at low temperatures (550°) (*Proc. Roy. Dublin Soc.*, February, 365; 1930). By carrying out the distillation in an atmosphere of coal gas, unusually high yields of tar (16·6 per cent) and ammonia (17·4 lb. per ton) were obtained. The peat itself contained 10 per cent of soluble wax and bitumen. Unfortunately, tars of all kinds are at a discount just now, and as these tars have the 'low temperature' character, their value at present is problematical. In the April number of the same publication, C. O'Sullivan and J. Reilly have recorded investigations showing that the yields of tar are increased by distilling separately the wax extractable from the peat.

Low Temperature Carbonisation Tests.—In accordance with the scheme in vogue whereby the Department of Scientific and Industrial Research makes official tests of plants for the low temperature carbonisation of coal, the staff of the Fuel Research Board has carried out a 6-days trial of the 'Babcock' plant installed at the Dunston station of the Newcastle Electric Supply Co. This plant is unusual in that it is specially designed for the pre-carbonisation of boiler fuel and works in conjunction with a power station steam-raising unit. The retort tested was worked at its rated capacity, 30 tons per day of Northumberland coal slack being treated. The coal is first pre-dried by products of combustion and then carbonised by 'internal heat' by a mixture of steam with flue gases containing some oxygen. The coke produced (14·6 cwt. per ton of coal) is led straight on to the chain grate of the boiler stoker while the gas, of very low calorific value, is also consumed under the boiler. Of liquid products the yields were 16·4 gal. of tar and 2·5 gal. of spirit, these being the only by-products. Some of the coke was large enough for use on the domestic grate, for which it was very suitable. The test showed that the plant was technically successful and would eliminate the production of smoke in power-station practice. It should be remembered that the low value of the main product, coke, which must be produced in competition with cheap boiler slacks, makes the economic problem very difficult.

Ekatantalum.—The May number of the *Journal of the American Chemical Society* contains a paper by A. V. Grosse on element 91, or ekatantalum. The existence of such a metal, between thorium and uranium, was predicted by Mendeléeff in 1871, and at present three isotopes of it are known, all radioactive, namely, brevium, protoactinium and uranium *Z*. Of these, protoactinium is most important. It was discovered by Soddy, and independently by Hahn and Meitner, in 1917, and is, as its name indicates, the parent of the actinium series. It occurs in Nature in considerable quantities, uranium ore containing about 0·6 gm. per gm. of radium. Up to the present, all attempts to concentrate and isolate protoactinium have been unsuccessful, and this has been due, according to Grosse, to a mistaken assumption that there would be a similarity in properties between the new element and tantalum. He arrived at the conclusion that it would be more basic than tantalum, and more analogous to thorium and uranium. This prediction has been verified, and Grosse has succeeded in extracting about 40 mgm. of the element. The experiments on its chemical properties were carried out by ordinary chemical methods, using 10 mgm. or more of material. The oxides of ekatantalum and tantalum have only one reaction in common, the solubility in hydrofluoric acid. Attempts by previous experimenters to concentrate protoactinium in tantalum are now known to have had the effect of removing from the tantalum preparations the last traces of protoactinium which they may have adsorbed.

Deep Sea Investigations by Submarine Observation Chamber.

ON June 11, 1930, in lat. 32° 16′ N., long. 64° 39′ W., in the Atlantic Ocean off Bermuda, Dr. William Beebe, accompanied by Mr. Otis Barton, descended to a depth of 1426 feet below the surface of the sea.[1]

This announcement marks a new era in the exploration of the sea. All previous diving records shrink into insignificance compared with this depth; it was with no wish for record-making achievements that the descent was undertaken, but a real explorer's desire to see the animals beneath the waters as they live and not at second-hand from the collections of deep sea nets.

The construction of the chamber was financed by Mr. Barton, and he and Dr. Beebe, working from the New York Zoological Society's Oceanographic Expedition's headquarters at Nonsuch Island, have now made several descents, of which three were to a depth of 800 feet and one to 1426 feet. The chamber is a steel sphere 57·3 in. in outside diameter and 1½ in. thick. Observations could be made through a 6 in. diameter port fitted with a quartz window. Outside the window was hung a bag of decayed fish and some baited hooks, and a strong electric searchlight could be used to illumine the surrounding water. Telephonic communication was maintained with the ship above and a supply of oxygen carried.

One of the most striking phenomena was the " blue brilliance of the watery light to the naked eye, long after every particle of colour had been drained from the spectrum ". The visual degeneration of the spectrum was observed, in connexion with an intensity metre. In Dr. Beebe's own words:[2] "The red had gone completely a few feet down . . . ; orange had been absorbed at sixty feet below the surface and yellow at less than 400. At our depth (800 feet) lavender, too, was non-existent, together with the two opposite ends of the spectrum, infra-red and ultra-violet, while green still persisted, but greatly diluted. All that remained to our straining eyes were violet and blue, but blue such as no living man had ever seen."

It proved quite possible to observe pelagic animals drifting and swimming past the window, such as medusæ, shrimps, and fish, and about a dozen true bathypelagic fish were identified. A very interesting result of these observations was the presence of certain species of fish and invertebrates in water layers well above the depth at which their occurrence is first indicated by net catches in the daytime.

Four descents have also been made in water up to 350 feet in depth along the shelving bottom of the Bermudian insular shelf as the vessel drifted seawards. Such exploration revealed a new fish fauna at these offshore depths, the recognisable shore fish also being of great size.

The observations will be continued another year, and it is to be hoped that this new weapon of marine research has come to stay and that similar submarine observation chambers may be built in time for a study of the floor of shallower seas and the habits of food fishes. Already shallow water diving has proved its scientific value. We shall await Dr. Beebe's and Mr. Barton's full reports with great interest.

The Leakey-Harper Drawing Machine.

IN many branches of science, and more especially in zoology, palæontology, anthropology, and anatomy, it is often necessary to make illustrations of irregular and intricate objects, which must be true to scale and accurate in detail. It has been found that photography does not fulfil the requirements, and the illustrations have in the past been made by accurate freehand drawings. Such drawings require a large number of measurements to be made, and if a high degree of accuracy is required the work entailed is very considerable. If the specimen being drawn is of a fragile nature, considerable risks are involved because of the amount of handling entailed.

The drawing machine illustrated in Fig. 1 has been especially designed by the Cambridge Instrument Co., Ltd., 45 Grosvenor Place, London, S.W.1, to enable true-to-size drawings to be made quickly and conveniently, with the minimum amount of handling. It further makes it possible for drawings to be made of any of the six different views which represent six projections on to the sides of a cube surrounding the object, without moving the specimen after it has been once put into position.

This fact is of special importance in that branch of work for which the instrument was originally suggested by L. S. Leakey, namely, making drawings of human skulls, where it is often necessary to make drawings of the profile, full face, base, etc., with the skull orientated on the Frankfurt plane. The instrument is very easy to use and combines both greater accuracy and greater speed in the drawing of any object. The outline drawing of a skull that is illustrated in Fig. 2, including the teeth, sutures, and orifices, took forty-five minutes. A similar drawing done by the ordinary measurement and freehand method would have taken approximately twelve hours, whilst the degree of accuracy obtained on a complete set of freehand drawings could not equal that obtained by the drawing machine.

The principle of operation of the Leakey-Harper machine (Fig. 1) is as follows: A telescope, *A*, fitted with crosslines and with a horizontal line of sight, is fixed rigidly to a carriage that is capable of horizontal and vertical movement in a plane normal to its axis but so that the line of sight remains accurately parallel to its original direction. The horizontal and vertical movements of the telescope are obtained by rotating two hand wheels, one on the left hand, *B*, effecting the horizontal adjustment and one on the right, *C*, the vertical adjustment. Rigidly attached to the hand wheels, and at right angles to one another, are two long screws, one on the left hand carrying the telescope carriage, so that any rotation of the wheel moves the telescope in a horizontal direction. Rotation of the wheel on the right moves the telescope vertically. Attached to the base of the telescope carriage is a pencil, *D*, that inscribes in one plane on a sheet of paper the horizontal and vertical movements of the telescope.

Attached to the pencil is a circular soft iron plate that is supported above a solenoid by a helical spring; the pencil itself is fed through the solenoid so that the point is supported immediately above the paper; when a current is passed through the solenoid the soft iron plate is magnetically attracted and the pencil pulled down until it is in contact with the paper. When the circuit is broken the pencil is automatically raised from the paper.

The object to be drawn is mounted on a square glass plate on which have been inscribed crosslines intersecting in the centre at angles of 90° to one another; this plate is then placed upon a glass shelf, *E*, similarly ruled, that is fitted in an open frame in a position opposite to the line of sight of the telescope. To obtain an alternative view of the object to the line of sight it is only necessary to rotate the subsidiary glass plate through an angle of 90°, as indicated by the ruled lines, and by rotating the plate in this way through a succession of right angles the four different views necessary for a complete set of drawings may be obtained. The plan views of the top and bottom of the object are obtained by two large plane mirrors, *F*, fixed to the frame at an angle of 45° to the horizontal, one above and the other below the specimen to be drawn. These mirrors reflect the desired images and it is only necessary to raise or lower the frame carrying

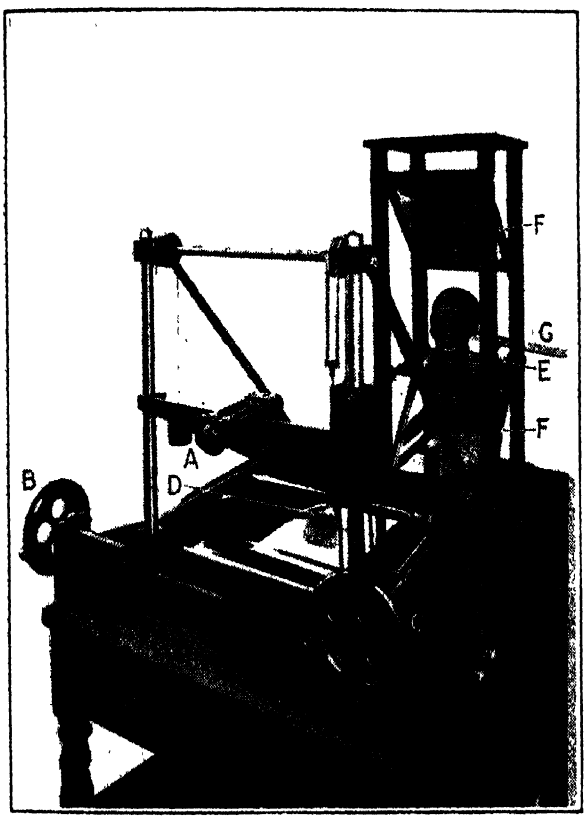

FIG. 1.

the object until the reflected image is in the line of sight of the telescope. The framework carrying the specimen is open, but a suitably coloured curtain may always be hung behind the object to give contrast when drawing edges of white or black objects.

To make a drawing of a skull, the specimen is set up on the glass plate on the Frankfurt or any other desired plane; the skull may be supported by a block and held in position by small pieces of plasticine. Fragile fragmentary specimens may be supported by a moulded block of plasticine, but it will be recognised that this will prevent a detailed drawing of the base view being made without resetting the specimen. The observer sets the telescope so that the intersection of the crosslines in the telescope coincides with the outer extremity of the skull; the right hand wheel controlling the vertical motion should then be rotated through the whole length of adjustment; this will cause a straight line to be drawn by the pencil on a sheet of paper that has been previously fixed to the drawing board. By suitably dividing this line a scale is obtained on which vertical measurements may be made. Similarly, the lowest extremity of the skull may be taken and a line drawn by means of the horizontal adjustment to provide the horizontal scale.

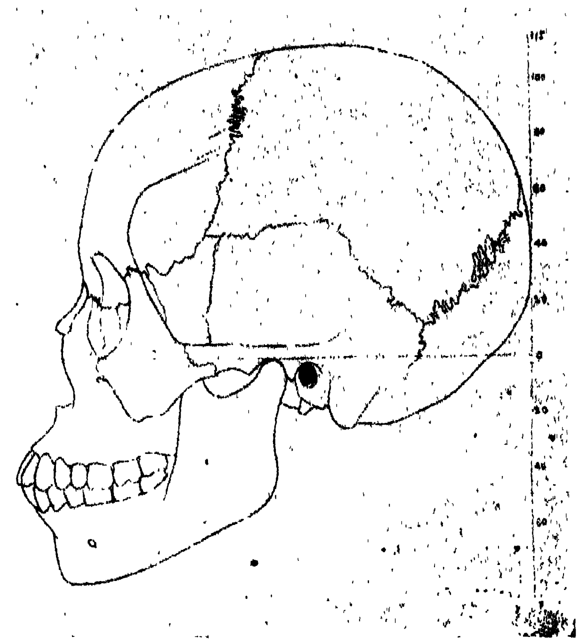

FIG. 2

The telescope is then focused and the crossline intersection made coincident with a point on the main outline of the skull; by rotating the hand wheels the observer may make the telescope traverse the complete outline, and in this way make the pencil draw out the projection of the complete skull in this plane. Similarly the sutures, orbits, teeth, etc. can be drawn in detail.

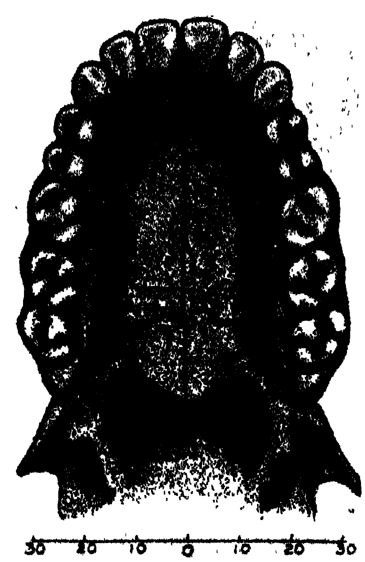

FIG. 3.

A further attachment has been devised by Mr. E. Smith to enable the depths and contours of orifices or cavities in the specimens to be drawn. This is of

great service in connexion with drawings of skulls, as it is often desirable to show on profile drawings the depth and the shape of the orbit, palate, etc. The attachment for this work consists of a U-shaped metal pointer with parallel prongs, *G*, that is capable of horizontal and vertical adjustment and which is carried on an arm that is fixed in a runner at the side of the frame supporting the specimen; this runner is also capable of vertical adjustment. The width between the prongs is such that it is rather larger than half the maximum width of an average skull and the length of each of the prongs is precisely equal, so that the pointed tips are exactly in the same line of sight when viewed by the telescope. It follows that if the posterior prong is placed within a cavity and thereby hidden from view, then the anterior will indicate the actual depth of the cavity and by following the movements of the anterior pointer with the telescope an outline of the cavity may be drawn.

It will be appreciated that all subsequent measurements can be made on the drawings instead of on the object. This is of great convenience, as it enables drawings to be submitted for examination rather than the actual object; in addition, any number of precisely similar drawings may be made.

Although the machine was primarily designed for drawing skulls, it can be used to advantage in making a series of true to size drawings of any object in any plane where accuracy of detail combined with speed are a consideration.

The illustrations show the complete apparatus with a skull mounted in position for drawing, and also two drawings—one of a skull (Fig. 2) and the other of a palate (Fig. 3)—obtained with the instrument.

Recent Work on Vitamin D.

II.

CHEMISTRY.

VARIOUS colour tests have been proposed for the detection of vitamin D, but none of those yet described is specific. Thus W. A. Sexton (*Biochem. J.*, vol. 22, p. 1133; 1928) has investigated the reaction obtained by heating a source of vitamin D with aniline hydrochloride in excess of aniline, when a red colour is produced. It was found that in addition to cod-liver oil and irradiated ergosterol, a similar colour was given also by unsaturated ketones, such as cholestenone, oxycholestenone, oxycholesterylene and carvone: with saturated ketones, such as cholestane-4-one or camphor, only slight darkening of the mixture was observed. The results suggest, however, that the vitamin, or an accompanying irradiation product of ergosterol, is ketonic in character. The phosphomolybdotungstic acid test is even less characteristic; though cod-liver oil gives a positive reaction, irradiated ergosterol is negative. Ergosterol itself, however, shows certain colour reactions which not only are useful for detecting its presence in mixtures, but also throw light upon its chemical structure as well as that of some other sterols.

O. Rosenheim (*ibid.*, vol. 23, p. 47; 1929) has found that when it is warmed with chloral hydrate or its chloroformic solution treated with a concentrated aqueous solution of trichloroacetic acid, an immediate red colour is produced which soon changes to a deep blue (passing through a green in the case of chloral hydrate). So little as 0·005 mgm. can be detected. The red colour is also given by cholesterylene, ψ-cholestene, allocholesterol, and allositosterol, and is therefore dependent upon the presence of the $\Delta^{1,2}$ (or $\Delta^{1,13}$) ethenoid linkage: it is probable that a coloured carbonium salt is formed. The colour is discharged by water or alcohol. The final blue stage observed in the case of ergosterol is presumably due to the presence of the third double bond. Oxycholesterol gives a gentian blue colour with the reagents, which, however, shows only the absorption band of oxycholesterol and not those of the ergosterol blue.

I. M. Heilbron and F. S. Spring (*ibid.*, vol. 24, p. 133; 1930), in further studies of the structure of sterols, have investigated the reaction with bromine: ergosterol and certain hydrogenated derivatives of this substance which do not give the red colour with trichloroacetic acid, when dissolved in glacial acetic acid show a green colour on addition of a solution of bromine in chloroform. It appears that this reaction depends upon the $\Delta^{10,19}$ (or $\Delta^{10,11}$) ethenoid linkage, which is inert to hydrogenation: all cholesterol derivatives, for example, are easily hydrogenated completely; they fail to give the bromine test. Heilbron and Spring also direct attention to the fact that only those sterol compounds show selective absorption which contain the $\Delta^{1,13}$ (or $\Delta^{1,2}$) ethenoid linkage as one of two which are present in the molecule.

Since the discovery that ergosterol shows the highest antirachitic potency of any substance on irradiation with ultra-violet rays, search has been made for other substances which could be activated to a similar degree, but without success. Thus O. Rosenheim and T. A. Webster (*Biochem. J.*, vol. 22, p. 762; 1928) found that naturally occurring saturated sterols and artificially reduced sterols, cholesterol and sitosterol with one double bond, stigmasterol and cholesterylene with two were not activated on irradiation. Again, other unsaturated compounds containing three or more double bonds such as squalene, certain terpenes, sphingosine, and phrenosine were unable to replace ergosterol as precursors of vitamin D. Isomers of ergosterol, fungisterol from ergot and zymosterol from yeast, iso- and neo-ergosterol were equally impotent. The work on zymosterol was carried out by E. M. Hume, H. H. Smith, and I. Smedley-Maclean (*ibid.*, vol. 22, p. 980; 1928) and was complicated by the fact that the sterol still contained, after purification, as much as 5 per cent ergosterol, the impurity being detected by spectroscopic examination, since neither zymosterol nor fungisterol possesses any selective ultra-violet absorption. However, the biological test on rats showed that daily administration of $\frac{1}{20,000}$ mgm. irradiated ergosterol prevented rickets almost entirely, whilst the same slight activity was shown by doses of $\frac{1}{100,000}$ mgm. irradiated ergosterol and $\frac{1}{5000}$ mgm. irradiated zymosterol: hence the effect produced by the latter can be ascribed to its ergosterol content.

In a further communication, Rosenheim and Webster (*ibid.*, vol. 22, p. 1426; 1928) give details of their examination of irradiated fungisterol for antirachitic potency as well as results obtained with two other sterols isolated from ergot. The fungisterol and one of the others contained small amounts of ergosterol as shown by spectroscopic examination and their biological activity after irradiation was low and certainly due to the presence of irradiated ergosterol. The third sterol showed no absorption bands, gave a negative colour test for ergosterol and was completely inactive after irradiation. All the evidence so far obtained, therefore, suggests that ergosterol is the only naturally occurring precursor of vitamin D.

In following the course of the reaction ergosterol→vitamin D, it has been found that other products be-

sides the vitamin are formed: in fact, under conditions of irradiation such as are frequently employed, the latter forms only a small proportion of these products. Observation of the changes in the absorption bands of ergosterol forms a convenient method of following the course of the reaction, but potency tests are necessary before any particular band can be assigned to vitamin D, more especially since the changes vary to some extent according to the conditions of irradiation. By following these changes, Heilbron and his co-workers were first led to suspect that 'pure cholesterol' contained a contaminating provitamin, and finally to suggest that vitamin D was characterised by a band at 2470 A.; the ergosterol bands are at 2935 A., 2815 A., and 2700 A. Irradiation was carried out in alcoholic solution for 60 min. (I. M. Heilbron, E. D. Kamm, and R. A. Morton, *Biochem. J.*, vol. 21, pp. 78 and 1279; 1927; *J. Chem. Soc.*, p. 2000; 1927).

T. A. Webster and R. B. Bourdillon (*Biochem. Jour.*, vol. 22, p. 1223; 1928) found that irradiation with rays of wave-length longer than 2700 A., by the use of a filter of alcoholic cobalt chloride which cuts off the shorter rays, did not alter the equilibrium reached and that exposure of the solution of ergosterol during irradiation to temperatures ranging from - 18° to 77·8° did not alter the potency of the final product, although at temperatures of -183° and -195° the preparations were markedly less active: these results suggest that the temperature coefficients of the changes causing production and destruction of the vitamin are similar and small and that both reactions are directly photochemical in Nature. A highly active preparation was obtained by a short irradiation followed by removal of the bulk of the unchanged ergosterol with digitonin, evaporation to dryness and extraction in ether to remove traces of digitonin and ergosterol digitonide. The product was a glassy solid, melting at about 30° and much more soluble than the original ergosterol in organic solvents. When the absorption spectra of the irradiation products were studied, it was found that the first change was a marked increase in the absorption below 3000 A., especially in the regions 3200-2900 A., 2650-2500 A., and 2900-2700 A. More prolonged irradiation decreased the absorption and, at the same time, the activity. The authors conclude that vitamin D probably has an absorption maximum at 2800 or 2900 A. and from it is formed a secondary product with an absorption maximum at about 2300 A. Still longer irradiation of the products first obtained leads to complete disappearance of both absorption and activity. They point out that the presence of a band together with some activity in a preparation does not indicate that the band is to be attributed to the vitamin, unless a quantitative relation between such absorption and activity can be demonstrated.

Bourdillon and Webster and their co-workers consider the absorption spectrum of vitamin D also in a later paper (*Proc. Roy. Soc.*, B, vol. 104, p. 561; 1929). Their evidence suggests that three substances are formed in succession by the irradiation of ergosterol: the first (which is vitamin D) shows increased absorption as compared with ergosterol in the region 2500-3100 A. with maxima at about 2800 A. and 2700 A. More prolonged irradiation results in decrease in the absorption in this region with a concomitant increase in that between 2300 and 2500 A. and finally in almost complete disappearance of any absorption in the ultra-violet region. Quantitative comparisons of absorption spectra and antirachitic activity showed a roughly linear relation between intensity of absorption at 2700-3100 A. and potency, so that presumably the substance first formed is the vitamin. The other two substances are inactive. When a filter cutting off all radiation below 2650 A. was used, there was a marked decrease in the formation of vitamin D, suggesting that shorter wave-lengths favour its production rather than its destruction.

The irradiation was carried out usually in alcoholic solution in the absence of oxygen: vitamin D was not easily oxidised in alcoholic solution, but very readily when exposed dry to oxygen at 100°. By calculations depending on the rate of destruction of ergosterol (determined gravimetrically) and the rate of production of absorption due to vitamin D, it was found that the purest preparations obtained probably contained about 55 per cent of the vitamin. The minimum dose detectable biologically was about $2·5 \times 10^{-9}$ gm. or, in 14 days, $3·5 \times 10^{-8}$ gm. If only half this was vitamin D, the smallest detectable dose of the pure vitamin would be $1·9 \times 10^{-8}$ gm., a figure which agrees closely with Steenbock's and Coward's estimates.

E. H. Reerink and A. van Wijk (*Biochem. J.*, vol. 23, p. 1294; 1929) irradiated ergosterol in solution in hexane, exposing it to wave-lengths longer than 2750 A. and to the wave-length 2540 A. by interposing between the mercury arc and the solution filters of benzene solution or chlorine gas and potassium nitrate solution, respectively. Oxygen was rigidly excluded. With the long wave irradiation it was found that the absorption increased at first over the whole range, diminishing as irradiation proceeded in the long wave range. At 2820 A., absorption decreased from the beginning, but at 2715 A. it at first increased. It was possible to calculate that for the first 15 min. the conversion of ergosterol into vitamin D was the only reaction taking place and that in this time about half the ergosterol was converted. More prolonged irradiation resulted in slow destruction of the vitamin and disappearance of the above bands with the development of an ill-defined band at 2400-2500 A. The product of a short irradiation was highly active and was obtained in the crystalline state, free from ergosterol, provided that oxygen was rigidly excluded during all manipulations: the crystals had a melting point below 0°.

Irradiation at 2540 A. resulted in an increase in absorption over the whole range, including 2800 A., the increase being much more marked than with the long wave irradiation: the absorption at 2930 A. and 2820 A. increased much more than that at 2715 A.: further irradiation resulted in almost complete disappearance of the absorption. The vitamin was formed only during the first few minutes and was then rapidly destroyed: the most potent preparation had an activity of only about a tenth of that of the material obtained by long wave irradiation. In certain respects these results do not agree with those obtained by Bourdillon and Webster *et al.*, and it is obvious that further work is required before agreement is reached on the absorption spectrum of vitamin D, but the preparation of pure specimens appears now to be assured.*

It may be pointed out that the stability of the vitamin may be influenced by the presence of accompanying compounds in a similar manner to the parent substance ergosterol. H. King, O. Rosenheim, and T. A. Webster (*Biochem. Jour.*, vol. 23, p. 166; 1929) point out that although ergosterol itself is labile, as a contaminant of cholesterol it appears stable: they have, in fact, found it present in the cholesterol esters isolated from the brain of a mummy 1400 years old, both by colour test and also by obtaining an antirachitic product of the same order of potency as irradiated 'cholesterol', by its irradiation.

* In a recent note in our columns (NATURE, vol. 125, p. 635; 1930), Bourdillon, Jenkins, and Webster state that they have now come to the conclusion that the absorption band at 2800 A. is not that of vitamin D, but of a decomposition product: the vitamin shows low absorption at this wave-length.

University and Educational Intelligence.

CAMBRIDGE.—The electors to the Woodwardian professorship of geology have elected Prof. O. T. Jones, professor of geology and mineralogy at the University of Manchester, to succeed Prof. J. E. Marr, who will vacate the post on Sept. 30 next. Prof. Jones, who was educated at Pencader Grammar School and the University College of Wales, Aberystwyth, took first class honours in both parts of the Natural Sciences Tripos at Cambridge, where he also gained the Wiltshire prize, the Harkness prize, and the Sedgwick essay prize. He has been professor of geology at Manchester since 1910.

The Vice-Chancellor announces that the annual Treasury grant payable to the University as from the beginning of the academic year 1930–31 will be £107,500, an increase of £14,000.

Dr. G. H. F. Nuttall has been re-elected into the Quick professorship of biology.

The Appointments Committee of the Faculty of Agriculture and Forestry has appointed H. E. Woodward to be University lecturer in agricultural chemistry, W. K. Hubble to be University demonstrator in agriculture, and Dr. Marshall to be director of the Animal Nutrition Institute. This Committee will shortly proceed to appoint a University lecturer in agricultural chemistry to give instruction in soil science. Particulars as to stipend and duties may be obtained from the Secretary, Appointments Committee, Department of Agriculture, University of Cambridge.

The Vice-Chancellor has appointed Sir Arthur Evans to the Frazer lectureship in social anthropology for the academical year 1930–31. The Managers of the Benn W. Levy Research Studentship in Biochemistry have elected L. H. Strickland, Christ's College, to the studentship.

LONDON.—Dr. J. M. W. Morison, lecturer in radiology at the University of Edinburgh, has been appointed to the University chair of radiology tenable at the Cancer Hospital (Free). Dr. H. D. K. Drew, lecturer in the Department of Chemistry at the University of Birmingham, has been appointed to the University readership in organic chemistry tenable at East London College.

The following appointments have been made to the staff of Birkbeck College: Mr. H. C. K. Henderson to be lecturer in geography; Mr. C. E. M. Joad to be lecturer in philosophy and psychology, and Mrs. M. E. Robinson to be lecturer in economics.

At a meeting of the Court of the University held on July 30, it was announced that the London County Council will, subject to certain conditions, make a total capital grant of £250,000 towards the erection and equipment of buildings on the Bloomsbury site, and a capital grant for the quinquennium 1930–35 of £150,000 towards the capital requirements of schools not connected with the Bloomsbury site.

MANCHESTER.—The Council, at a recent meeting, unanimously adopted a resolution expressing to Prof. F. E. Weiss its very deep regret on his retirement from the George Harrison chair of botany, which he has held since 1892. "During his tenure of the Chair, he has built up a great School of Botany, which bears a distinguished name both at home and abroad. It is renowned for the researches which have been carried out by the members of the School and for the unusually large number of men and women it has trained who now occupy positions of influence in many spheres of botanical work. . . . His singleness of purpose, inspiration, and exceptional abilities as a leader and administrator have been a constant source of strength, and have done much to place the University of Manchester in the position it now occupies."

Historic Natural Events.

Aug. 10, 1591. Atlantic Gales.—A fleet of 77 sail, which left Havana for Spain on July 17, encountered a terrible gale on Aug. 10, and the commander of the fleet with 500 men perished. Three or four days later, in another gale, five or six of the largest ships with all their crews and the vice-admiral were lost. About the end of August, in lat. 38° N., they experienced a third gale in which 22 sail perished. Finally, within sight of Flores, the survivors were scattered by a fourth gale on Sept. 6; very few reached Spain.

Aug. 10, 1893. Heavy Rain at Preston.—At Preston, Lancashire, 2·09 in. of rain fell in 35 minutes, but the observer was of opinion that 1·25 in. of rain and hail fell in five minutes. This storm did a great amount of damage.

Aug. 10, 1901. Hailstorm.—A series of very violent thunderstorms brought terrific falls of hail during the morning in Derbyshire, Yorkshire, and the south-east of Scotland. Great damage was caused to crops, especially near Galashiels, and thousands of panes of glass were broken. The violent storm was very brief, but the hail blocked up the drains and caused flooding.

Aug. 10-16, 1924. Aberrant Typhoon in the Pacific.—A typhoon which originated in the western Pacific, near the Marianna Islands, on Aug. 5, followed a most unusual track. The majority of these disturbances either travel steadily towards the west or north-west until they strike the mainland of Asia, when they fill up, or else follow a simple parabolic path, travelling first towards the west-north-west, then turning north and finally north-east. This particular example, however, a well-developed, violent typhoon, followed a looped track south-west of Japan, travelling south-west on Aug. 10, south and south-east on Aug. 11, and very slowly eastwards on Aug. 12-16. Finally on Aug. 17 it resumed its normal track and continued across the Sea of Japan. So unusual was the looped track that a steamer was wrecked because its captain believed that a typhoon could not possibly advance towards the south-west, and neglected to take the necessary precautions.

Aug. 12, 1582. Storm in Norfolk.—There was a great thunderstorm and whirlwind, with hailstones shaped like rowels of spurs, two or three inches in circumference. On the same night arose the greatest storm since the "Calais" storm on Jan. 7, 1558. Many houses, barns, and gates were blown down, and many vessels were lost.

Aug. 12, 1891. Record Rainfall.—At Campo, San Diego, Calif., on Aug. 12, 1891, a total of 11·50 in. of rain fell in one hour. This is the world's record for one hour's precipitation.

Aug. 13, 1868. Peruvian Earthquake Sea-waves.—The epicentre of the earthquake was near Arica on the coast of Peru. The resulting sea-waves were observed along the South American coast from the Chincha Islands on the north to near Valdivia on the south, places that are 2000 miles apart. They were also recorded in the Hawaiian Islands (6218 miles), Samoa (6633 miles), New Zealand (7047 miles), and New South Wales (8500 miles).

Aug. 14-27, 1873. Nova Scotia Cyclone.—A violent storm, after traversing the West Indies, travelled northward off the east coast of the United States, causing an immense amount of damage. It is said that 1223 vessels were wrecked, and at least 223 lives were lost. The storm played havoc with the fishing fleets of Canada and the United States, and was long remembered as the 'Nova Scotia Cyclone'.

Aug. 15, 1537. Hailstones in Central Europe.—At Gottwick, Austria, men and beasts were killed by hail. At Bologna the hailstones were said to have weighed 28 pounds. As this weight would give them a diameter of more than nine inches, it must be regarded as greatly exaggerated.

Aug. 15, 1905. Thunderstorm over the West of England.—A thunderstorm of exceptional violence occurred over Devon and Somerset during the evening, accompanied by heavy rain. There was much damage by lightning, buildings being set on fire and many cattle killed, but there is no record of the loss of human life.

Aug. 16, 1664. Thunderstorm.—Pepys wrote under this date: "Wakened about two o'clock this morning with the sound of thunder, which lasted for an hour, with such continued lightnings, not flashes, but flames, that all the sky and ayre was light; and that for a great while, not a minute's space between new flames all the time; such a thing as I never did see nor could have believed had ever been in nature. . . . And that accompanied by such a storm of rain as I never heard in my life; . . . it seems it has been here and all up and down the countrie hereabouts the like tempest, Sir W. Batten saying much of the greatness thereof at Epsum."

Societies and Academies.

PARIS.

Academy of Sciences, June 11.—**P. Villard**: The reduction of soda by hydrogen. Caustic soda, heated in a current of hydrogen at 800°-900° C., gives sufficient sodium vapour to reverse the sodium lines and to cut off all the light from a sodium flame. This result cannot be due to dissociation, since at the same temperature the replacement of the hydrogen by nitrogen causes the sodium vapour to disappear.—**Louis Roy**: The propagation of waves on elastic surfaces with three parameters.—**Paul Vuillemin**: A new species, *Corethropsis Puntonii*.—**O. Borůvka**: The surfaces represented by spherical functions of the first species.—**Ch. Sadron**: The ferromagnetism of the alloys of nickel and chromium. The study of the magnetic properties of nichrome alloys has been made by Safranek. On the same specimens the author has studied the saturations at the absolute zero and the ferromagnetic Curie points.—**Léon Bertrand**: The Trias of the neighbourhood of Betchat and of Salies-du-Salat.

June 16.—**Léon Lecornu**: Funicular surfaces.—**V. Grignard** and **J. Colonge**: The condensation of ketones. Extension of the classical method. The substitution of hydrochloric acid by hydrobromic and hydriodic acids gives higher yields, and some ketones which resist the condensing action of hydrochloric acid suffer condensation in the presence of hydrobromic acid.—**Léon Guillet** and **Marcel Ballay**: The influence of tempering on the electrical resistance and resistance to shearing of the silicon-aluminium alloys. The electrical resistance of pure aluminium.—**Jean Rey** was elected a member of the division of the applications of science to industry.—**L. Abélès**: The nomographic representation of analytical functions. Application to complex trigonometry.—**Mme. Julie Różańska**: The continued decompositions of surfaces into Cantorian curves.—**André Roussel**: Functions the infinitesimal increase of which has a given expression.—**Marcel Winants**: Linear differential equation of the third order and the integral curve passing through three given points.—**M. Fekete**: The changes of sign of a continuous function in an interval.—**Vignaux**: A method of summation of divergent integrals.—**H. E. Bray**: Functions with finite deviation.—**P. J. Myrberg**: The existence of Green's function for a given plane domain.—**G. Maneff**: Gravitation and the energy at the zero.—**Al. Proca**: Dirac's equation.—**N. Stoyko**: The influence of the terms of the third and fourth orders in the use of E. Esclangon's method for the determination of the orbit of a star. Application to the trans-Neptunian body.—**Ernest Esclangon**: Remarks on the preceding note.—**Fernand Baldet**: The nucleus of the Schwassmann-Wachmann comet (1930*d*). The nucleus does not appear to have had a diameter much greater than 400 metres, and is at least as small as that of the Pons-Winnecke comet.—**L. Décombe**: The undulatory theory of quantic phenomena. New results.—**F. Holweck** and **P. Lejay**: A portable instrument for the rapid determination of gravity.—**H. Muraour** and **G. Aunis**: The agreement between calculated explosion pressures and experimental explosion pressures. The calculated explosion pressures, starting with the new specific heats of Nernst and Wohl, for the gaseous mixture obtained in the experiments, are in complete agreement with the experimental pressures corrected for cooling.—**R. Forrer** and **J. Schneider**: The production by annealing of two states of pure iron, stable at the ordinary temperature.—**Armand de Gramont** and **George Mabboux**: The comparison of piezoelectric quartz oscillating at slightly differing frequencies.—**L. Abonnenc**: The measurement of the magnetisation coefficient of aqueous solutions by the method of falling drops. The method has been applied to measure the diamagnetism of the halogen ions. The results are in good agreement with the values obtained by Hocart by a different method.—**A. Turpain** and **R. de Bony de Lavergne**: An ultramicroscope permitting the direct projection of ultramicroscopic tests and the Brownian motion.—**V. Fock**: The mechanics of the photons.—**F. Prevet**: The mode of action of boric acid on the phosphorescence of sulphides of zinc prepared by the explosion method. The use of boric acid in the preparation of phosphorescent zinc sulphide is known to increase the intensity and persistence of the phosphorescence. Attempts to replace boric acid by other substances have proved unsuccessful, and it is concluded that the boric anhydride acts by influencing the crystalline medium necessary for phosphorescence.—**R. Coustal**: Poisons and phosphorogens for phosphorescent zinc sulphide.—**E. Estanave**: Integral photographs obtained without objectives.—**Hubert Garrigue**: The passage of the continuous current in acetone.—**Georges Fournier**: A relation between the filiation capacity of radioactive atoms and the velocity of the α-rays which they emit.—**Augustin Boutaric** and **Mlle. Madeleine Roy**: The radioactivity of materials arising from old roofs. The radioactivity of substances exposed to the open air is not due to exposure to sun, but to contact with rain water. Rain water was collected on a roof and passed into a cistern containing a filter of sand and charcoal, the filtering material not being exposed to the sun: both the charcoal and the sand were clearly radioactive.—**W. Broniewski** and **J. Strasburger**: The structure of the copper-zinc alloys. The brasses were examined after long periods of annealing at 400° C. Curves are given showing the electrical conductivity, the temperature coefficient of the electrical resistance, the thermoelectric power with reference to lead and other physical properties. The compound CuZn appears on all the curves and there are indications of $CuZn_2$ and $CuZn_6$.—**H. Colin** and **A. Chaudun**: The complex between the enzyme and the products of hydrolysis during the diastatic inversion of sugar.—

Guichard, Clausmann, Billon and Lanthony: The hardness of cold-hardened and electrolytic nickel.—**G. Dupont and J. Allard**: The mechanism of the antoxygen action.—**H. Forestier**: The action of the magnetic field on the velocity of solution of iron in a solution of cupric chloride. The velocity increases rapidly with an increase in the strength of the magnetic field; with fields between 500 gauss and 4000 gauss the increase of velocity of solution is proportional to the strength of field. Above 4500 gauss the velocity of solution is independent of the magnetic field.—**Alfred Molnar**: New researches on the cold hardening of lead, tin, cadmium and zinc at different temperatures. A comparison of the hardening effects produced by slow and rapid extension. The latter presents all the characteristics of a cold-hardened metal.—**Jean Cournot and Jean Bary**: The treatment of siderurgical alloys with solutions of some metallic phosphates. A study of the effects of mixtures of various phosphates as regards the protection of mild steel against corrosion. Protection by phosphate of iron alone was unsatisfactory, the best results being obtained by using solutions of mixed phosphates, iron and zinc, or zinc and manganese.—**F. Taboury**: The action of sulphuric acid on mercury at the ordinary temperature. Sulphur dioxide is the only gaseous product and crystals of acid mercurous sulphate, Hg_2SO_4, H_2SO_4.—**Picon**: Mercury camphocarbonate and some derived mercurial products.—**Charles Combaluzier**: The limits of the Burdigalian deposits in Lower Provence.—**H. Derville**: Henriette marble, a reef constructed by calcareous Algæ.—**Yves Milon**: The presence of Globigerina limestones in the Bartonian of Sarthe.—**E. Huguenard, A. Magnan, and A. Planiol**: A method of measuring the turbulence of the atmosphere.—**Guilliermond, Dufrenoy, and Labrousse**: The germination of tobacco seeds in media containing neutral red: the coloration of the vacuome during the development of the seedlings.—**Mlle. Eudoxie Bachrach and Mme. Pillet**: The micro-incineration of diatoms without carapace.—**Aug. Chevalier**: The three periods of renewal of vegetation in Senegal.—**G. Nicolas and Mlle. Aggery**: A third example of generalised bacterial infection in plants.—**Marcel Chopin**: The additive mechanical properties of dough made of wheat flour.—**C. Vaney and A. Bonnet**: The phenomena of autotomy in *Spirographis Spallanzanii*.—**Jean Régnier and Guillaume Valette**: A study of the mode of fixation of cocaine hydrochloride on the nerve fibres. A comparison of the absorption of cocaine by animal charcoal and by nerve substance showed a close similarity as regards rapidity of fixation and shape of curves. These results indicate that cocaine is fixed on the nerve fibre by a normal process of adsorption.—**L. Lutz**: The soluble ferments secreted by the Hymenomycete fungi. The degradation of the ligneous material.—**M. Lemoigne and P. Monguillon**: The presence of acetylmethylcarbinol and of 2.3. butylene glycol in the higher plants. Formation during germination.—**Claude Fromageot and Mlle. M. Watremez**: Comparison between the buffering powers of glycocoll and glycylglycine.—**Radu Codreanu**: The nutrition and action on the host of *Symbiocladius rhithrogenæ*.

GENEVA.

Society of Physics and Natural History, June 19.—**Leon W. Collet**: Preliminary report on the geological expedition of Harvard University in the Canadian Rockies (1929). The Canadian Rockies, from their eastern border to Yellow Head Pass, are made up of seven 'blocks' thrust one over the other from west to east, and separated by 'clean cut thrusts' of the type of the Northwest Highlands of Scotland. The Athabasca valley, from the town of Jasper to the eastern border of the Rockies, follows an axis depression of the thrust masses. The quartzites forming the mountains to the west of Maligne lake, as far as the Tonkin valley, are of Lower Cambrian age and not of Mesozoic age. Ammonites found in the Jurassic black shales show that upper Lias and Bajocian are present in the interior of the Canadian Rockies in Jasper National Park.—**L. Reverdin**: The neolithic fauna of the station of Port Conty (St. Aubin, Neuchâtel) from material collected from 1928 to 1930. Two groups of deposits belonging to the old and middle neolithic yielded 273 and 73 specimens. These proved, from one group to the other, a variation from 70 to 50·8 per cent for the domestic species and from 30 to 49·2 per cent for the wild species.—**G. Tiercy**: The gravitational derivation of the solar rays and the thermal regime of the high plateaux. The author proposes a new theory capable of explaining the thermal advantage enjoyed by the high plateaux, especially the Asiatic plateau, as compared with other regions of the same latitude. The calculation allows the estimation of the order of magnitude of the age of the Asiatic protuberance, or 1400 millions, figures which agree with those based on radioactivity and relative to the time necessary for the terrestrial crust to have acquired its present chemical constitution starting with uranium and thorium.—**N. Danoz**: The free surface of the fluid stars. The author has applied Wavro's method to the study of the internal movements of the fluid stars, and has been able to establish the following: if the equator rotates more rapidly than the pole caps, the free surface is an ellipsoid compressed between the pole and the equator. In the contrary case, it will be an expanded ellipsoid.

ROME.

Royal National Academy of the Lincei, Mar. 16.—**A. Angeli**: Certain relationships between constitution and odour. Unlike the artificial musks (aromatic nitro-compounds) and violet ketones (ionone, etc.), the cyclic polymethylene carbonylic compounds described by Ruzicka, although having similar odours, are free from methyl groups. It is suggested that the presence in the molecules of these compounds of a large number of methylene groups may render possible deformations of the ring so as to produce lateral nodes able to act like methyl groups. Certain evidence in support of this view is advanced. **A. Angeli and A. Polverini**: The oxidising power of diazohydrates and their analogies with nitrous acid. Reactions are described which justify the argument that the three molecules, $O:O$, $(HON):O$, and $(C_6H_5 \cdot N_2H):O$, are analogous in structure and behaviour.—**A. Terracini**: The projective quasi-applicability of a surface on a plane.—**Luisa Pelosi**: Generalisation of a theorem of F. Neumann on the calculation of certain integrals.—**M. Calonghi**: The mean curvature of surfaces. It is shown how the consideration of geometric elements connected with a surface along an infinitesimal cycle leads naturally to the notion of mean curvature of the surface itself. The procedure approximates the mean curvature to the total curvature, the rigid connexion of which with the properties of the infinitesimal cycles traced in the surface is rendered evident by the theory of surface parallelism.—**G. Pfeiffer**: The integrals of S. Lie.—**G. Krall**: Point loads for rods with moment of inertia variable with discontinuity.—**W. Kusnetzoff**. The regularisation of the general problem of three bodies.—**G. Bargellini and Lydia Monti**: 2:6-Dibromophenetidine and 3:5-dibromophenetidine. Various derivatives of these two compounds have been prepared and compared.—**A. Baroni**: Diphenyl

polysulphides, sulphodiselenide, and selenodisulphide. The melting-points and densities (at 20° : 4°) of the various compounds described are: $(C_6H_5)_2S$, 62°, 1·353; $(C_6H_5)_2S_3$, 30°, 1·418; $(C_6H_5)_2Se_2$, 59°, 1·743; $(C_6H_5)_2S_2Se$, 50°-51°, 1·593; $(C_6H_5)_2Se_2S$, 55°, 1·873.—**S. Visco** : Hysteresis of electrical conductivity in colloidal solutions. The electrical conductivity of solutions of granular gelatine of various concentrations exhibits distinct hysteresis.—**Mario Betti** : Optical resolution of racemic aldehydes (1). By means of β-hydroxy-naphthylphenylaminomethane, which combines readily with aldehydes to form highly stable, crystalline compounds, the racemic form of *p*-methoxyhydratropic aldehyde has been resolved into the two optical isomerides. Other aldehydes may be similarly resolved.—**G. Bini** : A new method for the identification and determination of nitrates in waters. Quinosulphonic acid gives with NO_3 ions a coloration varying from pale green to brown according to the concentration of the ions, and serves as a satisfactory reagent for the detection and determination of nitrates in water. It is less sensitive than, and hence preferable to, pyrogallolsulphonic acid.—**G. Checchia-Rispoli** : A case of metamerism in an exocystic echinoid.—**Fausta Bertolini** : Regeneration of the digestive apparatus in holothurians. The emission of the whole of the intestinal tube, leaving in position the first tract of the œsophagus and the last part of the rectum, united by the thin mesenteric lamina, with subsequent regeneration of the digestive system, has been observed in *Stichopus regalis*, and appears to be relatively more frequent with this species than with the genus *Holothuria*.—**G. Cannicci** : Contribution to the study of glutathione in Teleostei (2). The proportions and variations of glutathione in various species are described.—**G. Brunelli and N. Apolloni** : Certain characteristics of Mediterranean lagoon associations.—**V. Rivera** : The biological action of penetrating radiation (cosmic or ultra-γ rays) on the development of seeds of land vegetables. Penetrating radiation has not only no positive influence on the germination of the seeds of land plants, but even exerts a slight depressive action, retarding the onset of germination or slowing the growth of seedlings.—**Silvia Colla** : Variations in the oxygen content of the hydrostatic bladders of certain brown algæ. The results of experiments on *Fucus serratus L.* show that oxygen is accumulated in these bladders on exposure to light and is consumed or eliminated in the dark, so that the accumulation of oxygen is to be regarded as a photosynthetic effect. A parallel phenomenon was noted by Stiles and Langdon with a species of *Neurocystis*.

VIENNA.

Academy of Sciences, May 8.—**L. Haberlandt** : Researches on the heart-hormone in invertebrates. Experiments were made on the excised hearts of snails, of *Helix pomatia* in Innsbruck, of *Aplysia* in Naples. Isolated hearts were put into Ringer's solution and kept until spontaneous or mechanically excitable pulsations ceased in a time which varied from some hours to three days. Extract of muscle from the foot (with Ringer) produced no pulsation when added; extract of heart muscle proved a stimulant. Heart-hormone preparation from vertebrates also proved exciting even in extreme dilutions. Also adrenalin stimulated *Helix* hearts, and extract of heart from cattle stimulated *Aplysia*.—**F. Wessely and G. H. Moser** : Synthesis and constitution of scutellarine.—**L. Kober** : Structural elements of the Apennines in Calabria and Sicily and of the Atlas in Algeria.—**H. Gräven** : A method for determining uranium, thorium and potassium in hand specimens of minerals and rocks.

May 15.—**W. Knapp** : The action of *o*-phthalyl-chloride on the methyl ethers of *p*-bromo-phenol and of *p*-bromo-thio-phenol.—**C. Mayr and G. Burger** : Potentiometric titration using mercurous nitrate and sodium oxalate as titration solutions.—**P. Goldmark and F. Kammer** : Methods for measuring the mobilities of ions in gases.—**H. P. Cornelius and M. Furlani-Cornelius** : The Insubric line from Tessin to the Tonale pass.—**M. Radakovic** : Determinants that can be made symmetrical.—**F. Halla and E. Mehl** : Fibrous structure of plastic sulphur.—**F. Witt** : The distribution of radium emanation between the liquid and solid phases of water and of benzol. Radium emanation is occluded not absorbed by ice.—**J. Hoffmann** : Coloration of glasses and some minerals by β- and γ-rays. Lead glasses are recognisable by characteristic fluorescence in ultra-violet light. Neutral atoms of the alkalis, also Pb, Ba and Zn may be causes of colour.—**K. Marbach** : The disturbance of the equilibrium of radium B and radium C in preparations freed from traces of emanation.

WASHINGTON, D.C.

National Academy of Sciences (*Proc.*, Vol. 16, No. 4, April 15).—**Jan Schilt** : The velocities of *B*-type stars.—**C. R. Burnham** : Genetical and cytological studies of semisterility and related phenomena in maize. Two new types of semisterile maize have been found and examined.—**H. J. Muller and L. M. Mott-Smith** : Evidence that natural radioactivity is inadequate to explain the frequency of 'natural' mutations. As measure of the intensity of radiation, the ionisation per cubic centimetre per second in air was used. The mutation rate in untreated *Drosophila* is about 1 : 150 of the highest rate artificially induced, whereas the intensities of natural and artificial radiations are in the ratio of 1 : 200,000. Thus the natural mutation frequency is at least 1300 times as high as it would be if caused by radiation normally received by the flies.—**J. H. Hildebrand and J. M. Carter** : The influence on the ideal solution laws of the distribution of polarity within the molecule. Using the data for benzene with nitrobenzene, the three dinitrobenzenes and 1-3-5 trinitrobenzene, it appears that it is the number and polarity of the substituent groups rather than the electric moment of the whole molecule which determine deviations from Raoult's law.—**Wilder D. Bancroft and C. E. Barnett** : Pentavalent nitrogen in organic compounds. The conditions under which organic nitrogen will add on hydrogen chloride stoichiometrically are brought together in eight generalisations.—**Wilder D. Bancroft and Herbert L. Davis** : The tautomeric form of malic acid. Changes in optical rotation and anomalous dispersion of *l*-malic acid in solution are due to two tautomeric forms in dynamic equilibrium; the lævo-acid is ordinary malic acid and the dextro-acid contains an ethylene oxide oxygen linkage and two hydroxyl groups attached to the same carbon.—**J. L. Walsh** : On the overconvergence of sequences of polynomials of best approximation.—**H. S. Vandiver** : Summary of results and proofs on Fermat's last theorem (fifth paper).—**G. A. Miller** : Groups generated by two given groups.—**A. Adrian Albert** : (1) On the structure of pure Riemann matrices with non-commutative multiplication algebras.—(2) On direct products, cyclic division algebras, and pure Riemann matrices.—**Joseph W. Ellis** : The near infra-red absorption spectrum of calcite. Three new bands with wave-lengths shorter than 1·7μ are reported and doublet structure has been observed in most of the bands in this region.—**Richard C. Tolman** : The effect of the annihilation of matter on the wave-length of light from the nebulæ. It is assumed that there is a general

transformation of matter taking place throughout the universe at a rate necessary to account for the radiation from stellar objects; a non-static line element for the universe is derived mathematically and its implications examined.

Official Publications Received.

British.

Commonwealth Bureau of Census and Statistics, Canberra. Official Year Book of the Commonwealth of Australia. No. 22, 1929. Prepared under Instructions from the Minister of State for Home Affairs by Chas. H. Wickens. Editor: John Stonham. Pp. xxxii+1074. (Melbourne: H. J. Green.) 5s.

University College of Wales, Aberystwyth: Welsh Plant Breeding Station. Grazing and Manurial Trials on Permanent and Prepared Swards: and Factors affecting Seed Production of Red Clover. (Series H, No. 11, Seasons 1921-1929.) Pp. iii+91. (Aberystwyth.) 3s. 6d.

The Journal of the Institution of Electrical Engineers. Edited by P. F. Rowell. Vol. 68, No. 403, July. Pp. 801-944+xxxii. (London: E. and F. N. Spon, Ltd.) 10s. 6d.

Cambridge Observatory. Annual Report of the Observatory Syndicate, 1929 May 19-1930 May 18. Pp. 8. (Cambridge.)

CONGRESS.

AUGUST 7 TO 15.

INTERNATIONAL HORTICULTURAL CONGRESS (in London).—*Papers to be read on Aug. 8, 11, and 13*:—

Prof. Priestley: Vegetative Reproduction from the Standpoint of Plant Anatomy.
Dr. Van der Lek: Anatomical Structure of Woody Plants in Relation to Vegetative Propagation.
Dr. R. Salaman: Vegetative Mutations.
Prof. E. Baur: Production of Mutations by External Stimulus.
Dr. F. E. Denny: The Excitation of Dormant Buds under External Influence.
John Innes Horticultural Institution: Graft Hybrids.
John Innes Horticultural Institution: Vegetative Production of Polyploids.
John Innes Horticultural Institution: Sterility.
G. E. Yerkes: Raising Root Stocks from Seed.
Dr. C. G. Dahl: Root Stocks from Seeds of known Parents.
Dr. R. J. D. Graham and L. B. Stewart: Special Methods of Practical Utility in the Vegetative Propagation of Plants.
Miss Mary E. Reid: The Influence of the Nutrient Conditions of Seeds and Cuttings upon the Development of Roots.
Prof. P. W. Zimmerman: Factors influencing Root Growth of Cuttings.
Dr. A. B. Stout: The Inter-relations between Vegetative Propagation and Seed Reproduction.
N. Esbjerg: Varieties grown on own Roots.

The Imperial Conference and Science.

IN the House of Commons on July 30, the Prime Minister, Mr. Ramsay MacDonald, stated that the Imperial Conference, which is to be held in the autumn, will afford an opportunity for the Home Government and representatives from the various parts of the British Empire to make a general survey and discuss all matters, both in the political and economic spheres, of common interest to the members of the British Commonwealth. These matters will be dealt with under three headings: (1) inter-imperial relations; (2) foreign policy and defence; (3) economic questions. As regards inter-imperial relations, particular questions for consideration will be the recommendations of the recent conference on the operation of Dominion legislation and other matters of a constitutional character cognate to and arising from those discussed in the Report of the Inter-Imperial Relations Committee of the Imperial Conference of 1926.

As regards foreign policy and defence, the agenda will cover the further development of peace and arbitration policy, and will include the question of the reduction and limitation of armaments. Obviously, any consideration of the problems arising out of the effort made by the constituent parts of the British Commonwealth to reduce and limit armaments must include in its scope the bearing of scientific research on the materials for defence. But even more obvious is the ultimate connexion between science and the economic questions to be considered by the Conference. These questions include the general one of the trade of the Empire, the effect of successive tariff changes, and the extent and effect of inter-imperial tariff preferences; bulk purchase and price stabilisation; oversea settlement; the past and future work of the Imperial Economic Committee, the Empire Marketing Board, and the Imperial Institute; co-operation in agricultural research (including cotton-growing), forestry, and minerals; special meetings of experts on industrial research and standardisation; transport and communications, including review of the work of the Imperial Shipping Committee and the Oversea Mechanical Transport Council, survey of steamship services and development of civil aviation, cable, radio, broadcasting, postal and news services.

The programme is certainly comprehensive. It includes consideration of a number of subjects around which the fiercest political controversy has raged for many years past in every part of the Commonwealth. The only grave omission is a

reference to any discussion on the effect of the return to the Gold Standard in 1925 on trade and industry, a subject which has lately become one of most serious concern to economists, industrialists, and financiers. But the programme will commend itself as an honest attempt to project into the field of discussion almost every subject worthy of consideration, however unpalatable some of them may be to certain members of His Majesty's Government, charged as they are with potentialities for exhibiting marked differences of opinion, not merely between the oversea members of the Commonwealth and the Home Government, but also between those representing the Home Government itself. It demonstrates, moreover, that since 1926 the emphasis of the Conference has been shifted from constitutional to economic questions, the basis of which must in future be free co-operation, each Dominion being the sole judge of the nature and extent of its co-operation.

It is interesting to compare the subjects for discussion at the Imperial Conference with those which engaged the attention of representatives from the non-self-governing dependencies of the Crown and Mandated Territories at the recent Colonial Office Conference. At that conference discussion ranged mainly around the methods by which the potential resources of the Colonial Empire could best be developed. The report of that Conference has already been issued,* and more than half of it is devoted to subjects of direct interest to scientific workers. It surveys in broad outline the administration of the scientific and technical departments of the Colonial Empire, with special reference to the possibilities of creating a unified agricultural service, the Imperial College of Agriculture, veterinary services and research, the organisation of work on animal husbandry, medical services and research and their bearing on the recent report of the Colonial Development Public Health Committee, the place of the biologist in the education services, and forest services and research. The work of the Empire Marketing Board in fostering general research and assisting various colonies to undertake *ad hoc* investigations into problems of special interest was reviewed, and consideration was given to the development of fisheries, the extension of cable and wireless communications, civil aviation, transport services, and the function of the Imperial Institute. No questions relating to tariffs were discussed, with the result that full time was given to and due emphasis laid on considerations of the place of science in the life of the subject races of the British Empire.

We do not suggest that consideration of tariffs and imperial preferences, or what has come to be regarded as the alternative, bulk purchase and stabilisation of prices, should not be adequately discussed by the assembly of imperial statesmen. Everything is to be gained by the ventilation of these subjects, more particularly if the protagonists of these economic dogmas will provide the Conference with adequate statistical data bearing on their convictions. But there is a danger that most of the plenary sessions of the Conference may be taken up by such discussions, and those questions dealing with the bearing of science and co-operation in scientific research upon the development of the resources of the Dominions will be relegated to sub-committees consisting solely of experts. The inevitable consequence will be that the proceedings of these sub-committees will receive scant attention from the popular organs of the Press, wedded as these are to acutely controversial matter which the Conference will provide in abundance, and their reports will be presented at the end of the Conference and hurriedly adopted without comment or discussion.

It may be urged that the prominence given at the Imperial Conference in 1926 to the need for the encouragement of scientific research is a guarantee that there will be the same interest in science at this one. We trust this may prove to be the case, but there is reason to doubt it. It has to be remembered that the late Lord Balfour presided over the Research Sub-Committee appointed by the last Imperial Conference. He presented its report to a plenary session. His was a personality which commanded attention. He added to political renown an intimate knowledge of the subject-matter he presented and an unrivalled capacity in a statesman for presenting the facts and the outlook of science to the uninitiated. Unfortunately, none of the statesmen at the forthcoming conference possesses this unique combination of qualities. It does not follow, of course, that the reports of the sub-committees of experts presented to the Conference will not be of the greatest importance, or that lack of publicity in the Press or adequate discussion at a plenary session necessarily means that their recommendations will not eventually be put into effect. But it does mean that a restatement of the claims of science to the attention of the civilised world and the bearing of science on world progress, as well as the re-emphasis of the place of science in education, must be made without rather than within the Conference,

* Colonial Office Conference, 1930. Summary of Proceedings (Cmd. 3628.) (London: H.M. Stationery Office.) 2*s*. net.

What is wanted is a mobilisation of the supporters of science to take part in a preliminary educative campaign. Help can be expected from certain statesmen no longer in office, of whom the most prominent in England are Mr. Amery, Mr. Ormsby-Gore, and Major Walter Elliott. They have already done much to awaken their political colleagues at home and in the Dominions and Colonies to the need for more earnest encouragement of scientific research, and they have in their recent Empire travels done much also to spread the gospel of science among the unofficial classes in the various countries which they have visited. But the task is primarily one for scientific workers themselves. They should not ignobly depend upon others to interpret their work for them. It is a confession of impotence. It is their obvious duty to the peoples of the Empire to make unmistakably clear the problems which confront them, what new problems the application of science has created for the civilised world, and what hope there is of their solution.

The next few weeks will provide scientific workers with their opportunity to take part in this useful and necessary form of propaganda. A splendid lead has been given them by Dr. A. C. D. Rivett, deputy chairman of the Australian Council for Scientific and Industrial Research. In an article which appeared in the *Times* of Aug. 7 he pointed out that the coming Imperial Conference, in exploring the possibilities of closer economic co-operation, would do well to realise the fact " that before political and administrative measures can attain full success in dealing with the interchange of products it is essential to reach as high a degree of efficiency as possible in methods of production in both primary and secondary industries ". He adds that it will not " be without significance politically if, by improved methods, Empire goods are able to compete in British markets with a smaller measure of artificial aid than is deemed by some to be necessary at present ". These improved methods, he suggests, must be based on scientific experiment and reasoning, so that " it becomes of major importance to ensure that the growing scientific powers of the Empire shall be strengthened by union and made available, in the full force so attained, for the solution of problems of production and marketing ".

Much of Dr. Rivett's article is devoted to a survey of the problems confronting pastoralists and agriculturists in Australia. The diseases which ravage their sheep, blow-fly, foot-rot, braxy-like diseases, internal parasitic troubles, caseous lymphadenitis, are all preventable, he avers. The beef industry in North and North-West Australia is threatened by the rapidly spreading buffalo-fly pest. The prickly-pear has more or less ruined 60,000,000 acres of valuable stock-raising land in Queensland. Ignorance of soil science has been responsible for the economic ruin of many agriculturists and the failure of settlement schemes.

Fortunately, Australian statesmen of all parties realise that it is wise economy to spend money, even at a time of acute financial depression, on those services to which alone they can look for a solution of such problems, and it is equally fortunate that those in control of their scientific services realise the importance of co-operation and the pooling of knowledge through the medium of the various imperial bureaux and imperial research institutions which now exist in the different countries of the Empire. What is true of Australia is also true of every British Dominion, and Great Britain can be proud to have created the institutions which have served as models for them all.

Nevertheless, it is not enough to have persuaded governments that production and distribution are best improved by the assiduous prosecution of scientific research and its application. Science has a greater and nobler rôle to play than that in world affairs. Science, in fact, cannot be dissociated from any aspect of policy which seeks to determine the future course of the form of civilisation for which science itself is mainly responsible.

The Wider Biochemistry.

Outlines of Biochemistry: the Organic Chemistry and the Physico-Chemical Reactions of Biologically Important Compounds and Systems. By Prof. Ross Aiken Gortner. Pp. xv + 793. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1929.) 30*s*. net.

IT will be generally agreed that, up to the present time, the development of biochemistry has been most active in those aspects of the science which are associated with medicine in general and with animal physiology in particular. Such, according to Prof. Gortner, has been the case in most of the universities of America, and such, most of us will agree, has likewise been the case in Great Britain. Biochemistry has not on that account suffered any undue restriction of its activities. The reviewer feels personally that the future development of biochemistry can best be secured by retaining and even widening the administrative contacts with physiology and especially with

animal physiology. But such a viewpoint in no sense implies a denial of the necessity for developing biochemistry as an independent science incorporating within its wide bounds the methods of any sister science which give promise of elucidating the mechanisms of the living plant or animal.

It is clear that during the last two decades the younger science has found increasing utility for the techniques of the older physico-chemical sciences, and this ever-widening scope of biochemistry is very well brought before us in " Outlines of Biochemistry ", which collates and amplifies the lecture material used in Prof. Gortner's classes in agricultural chemistry in the University of Minnesota. It must be made clear, however, that this is not a text-book of agricultural chemistry in the strict sense. It is much more. Thus it devotes ten chapters and 277 pages to a consideration of physico-chemical problems intimately associated with cellular chemistry. Some may regard this as an undue allowance in a book of this size, but they are adequately answered by the originality of selection and the freshness of treatment of the matter embodied in these chapters, much of it distinctly unusual in biochemical text-books. Prof. Gortner is certainly to be congratulated on his breadth of vision in the more physical fields of biochemistry. The remainder of the book covers the proteins, nitrogen bases and alkaloids, carbohydrates and allied compounds, tannins, plant pigments, lipides, essential oils, and, finally, the ' biocatalysts '—the vitamins and enzymes.

The proteins are very fully treated, and special mention may be made of Chapter xiv. on protein structure and isomerism, and of Chapter xix. on the biological reactions of the proteins. The latter is perhaps unduly brief, but the matter of both chapters is presented in a most stimulating manner. In the section on nitrogenous bases the newer work on thyroxine, ergothioneine, and spermine is included, but the references to glutathione will require alteration in later editions. The carbohydrates are well treated, and in all cases the pyranoside and furanoside formulæ are used for the stable and reactive isomers respectively of the monosaccharide components. There is a mistake in the formula of gentiobiose on page 543, the reducing glucose component being represented as glucofuranose instead of glucopyranose. Glucofuranose has not yet been found in any natural source, either free or in combination. There is some confusion on pp. 549 and 550 regarding the individual monosaccharide components of some of the lesser known tri- and tetra-saccharides. Moreover, the α-configuration is given to the glucosidic linkage in sucrose. The reviewer is not aware of the evidence upon which this is based. All these are minor slips and can readily be rectified in a later edition. In the section dealing with the polysaccharides there is included the extremely interesting work of Heidelberger and his associates on specific immunological carbohydrates, whilst the nature of the problems to be considered in relation to the internal structure of cellulose is well illustrated by diagrams from the papers of Sponsler and Dore on X-ray analysis of ramie fibres—both very welcome features in a text-book of biochemistry. The chapters on fats and oils, sterols, and lipides are perhaps less satisfactory than those already reviewed; the treatment, though efficient, strikes one as being somewhat less original and lacking a little in enthusiasm.

There are certain omissions which are perhaps explained by the circumstance that the book is based on courses of lectures to students of agricultural chemistry. This notwithstanding, one feels that the important field of biological oxidations and reductions—including some reference to that fundamental plant product, cytochrome—might well have been included in a comprehensive work of this type. Moreover, although melanin and its formation are referred to in various parts of the book, no mention is made of the important work of Raper in this field. The rôle of hexose phosphates in fermentation is dismissed in two lines, and no reference is made to the parallel phenomena of muscle chemistry.

The reviewer is well aware of the impossibility of the author's anticipating all the strictures of the critic determined to be critical, and the above remarks are advanced, not with the intention of casting any reflection upon Prof. Gortner's noteworthy contribution to the literature of biochemistry, but rather that they may serve as a guide to the reader as to what fields he may expect to find covered, and what omitted, in the impressive mass of well-ordered information embraced within the covers of this work. Textual references to the original literature are ample, and are extended in a series of general references at the end of the volume. " Outlines of Biochemistry " will be deservedly popular on both sides of the Atlantic, and it is the certainty of the demand for further editions that encourages the reviewer to stress his personal regrets regarding what is omitted. In no sense does it lessen his enthusiasm for what is included and treated so admirably.

J. P.

A Biologist in the New Hebrides.

Man and Animals in the New Hebrides. By Dr. John R. Baker. Pp. xiv + 200 + 17 plates. (London: George Routledge and Sons, Ltd., 1929.) 12*s*. 6*d*. net.

On two occasions, in 1922 and 1927, Dr. Baker spent five and seven months in the New Hebrides, bent on scientific pursuits. No one will read in his account of these explorations vivid or wordy descriptions of tropical scenery and tropical mankind; the style is matter of fact, rather abrupt, sometimes a little careless, but no one will gainsay the importance of the facts themselves, or but admire the pains taken by the author to make his investigations as thorough as difficult conditions would allow.

The rapid depopulation of Melanesia has exercised the minds of many travellers, and various recent writers have attributed it to a score of different causes. Dr. Baker makes his own contribution. In Espiritu Santo, where the expedition was based, relics of villages the inhabitants of which had died off were frequent amidst the dense forests of the interior, and an estimate made by an English resident of some twenty-five years' standing placed the population then at ten times its present numbers. A census of a considerable number of the villages brought out the striking fact that for each 100 females there were 159 males, the second highest male/female ratio recorded of any people in the world at the present day. While Dr. Baker admits that introduced diseases and abortion are the chief causes of depopulation, he agrees with Buxton in regarding this abnormal sex-ratio as a factor of great importance. Unless the birth-rate were very high, and here it is the reverse, no race could fail to decline under such conditions.

To our knowledge of the fauna of the islands Dr. Baker made very considerable additions, as witness his list of some 29 new species (mostly Arthropoda). Undoubtedly his most interesting faunistic survey was that of the almost hitherto unknown "Steaming Hill Lake" in the hollow of the ancient crater of Santa Maria. Of thirty species, ten are probably new to science, a large proportion; but we are not prepared to agree with the author when he suggests that the specific differences cannot possibly be regarded as "of use" to their possessors. The physical conditions of the lake are so peculiar, its altitude, relatively high temperature, and curious temperature gradient, that who is to say what variations they may induce?

On the sea-shore of the island of Gaua some excellent ecological observations were made. A study of the coral reef in the mass suggested a modification of the gradual subsidence theory of fringing reef formation. The new idea is that a relatively slight sinking, which need not be continued, may offer conditions suitable for a gradually broadening fringe of coral, since even in the presence of the reef the coast-line itself recedes before the erosive action of shore breakers. Instead, therefore, of expanding outwards from the original shore-line, the reef expands inwards over erosion-submerged coast. Detailed examination of the half-mile of reef brought to light a fairly definite zoning of coral genera, and even more definite was the zonal arrangement of holothurian genera and species revealed by a count of individuals from the shore to the edge of the reef, an observation which fits in with recent work on the zoning of mollusca on Scottish shores.

Finally, reference must be made to the scientific use to which the extraordinary abundance of intersexual pigs was put. The abnormality elsewhere is extremely rare amongst mammals, but in these islands, where pigs are the most highly valued of possessions, between ten and twenty intersexes occurred to every hundred normal males. The type is quite distinct from those known in Europe, and its abundance and variety have led the natives to classify the intersexes into seven recognisable groups. Dr. Baker traces the probable development of these different stages, and suggests a convincing theory of their origin and of their genetics.

This is an interesting book, because, touching upon many different subjects, it sees all from the point of view of the scientific student. J. R.

Infra-Red Spectroscopy.

Das ultrarote Spektrum. Von Prof. Dr. Clemens Schaefer und Dr. Frank Matossi. (Struktur der Materie in Einzeldarstellungen, herausgegeben von M. Born und J. Franck, Band 10.) Pp. vi + 400. (Berlin: Julius Springer, 1930.) 28 gold marks.

The remark has not infrequently been made that progress in scientific knowledge depends ultimately upon the discovery of new methods of technique and the perfection of older ones. However much one may wish to uphold the claims of pure theory, there remains the conviction that, broadly speaking, it is the experimentalists who set the pace, either in providing trustworthy data or, for various reasons, failing to do so. In few branches of physics has this been more obvious

than in research upon infra-red radiation and its reactions with matter. As the authors of the book now under review remind us, it was Herschel who discovered the existence of these radiations so long ago as 1800; yet other parts of the spectrum—X-rays, for example—came to light decades later and grew in importance far more rapidly. The reason is to be sought in the exceedingly difficult nature of experimentation in the infra-red. It is not too much to say that the conquests of the last few years have reduced many of the technical rebels to a satisfactory degree of subordination: a few, however, still offer stout resistance, and against them a war of attrition is probably the only course.

Prof. Schaefer is not only a pioneer in infra-red spectroscopy and the founder of an enthusiastic school of disciples which includes Dr. Matossi, but it has also come his way to hold chairs of both theoretical and experimental physics at various times. The book now before us is the work of labourers in a vineyard who take no delight in picking to bareness for the say-so of it, but who have garnered judiciously, assessing almost to perfection the value of the crop. It is this that has made the laboratories at Marburg and at Breslau institutions whereunto seekers may resort, and be certain that they will come away humbler and wiser.

After a short historical introduction, the reader is asked to face some seventy pages devoted to experimental affairs. It is all very valuable, and the fact that it comes first serves to stress the hardly won battle for technical supremacy. The only drawback is that it might give the impression that the subject is little beyond the sum of its inherent difficulties. The next chapter is more encouraging, and deals adequately with the questions of heat radiation and their theoretical significance. A brief but sufficient treatment of the general Maxwellian relations follows, together with the work of Rubens on optical constants. The reader may now pause and take breath, for it is here that the book changes its outlook.

So far, infra-red rays have done all that electromagnetic waves of such a range of frequencies should, they have fitted reasonably well into the classical scheme and have provided a host of traps for the unwary observer. The authors, however, are not amongst those who ruminate on past victories: they are about to show how this region of the spectrum is of the first importance as the means whereby the physicist probes into the nature of the molecule. Theoretically, in this the chemist should rejoice (though in practice he usually does no such thing), and the X-ray worker will benefit from evidence on crystal structure from directions whence he least expected it.

Chap. iv. is devoted to the infra-red spectra of gases and liquids. After a general treatment along what must now be called classical quantum lines, the authors expound such portions of the new mechanics as are directly applicable. One wonders whether so much space need have been given to the Hamiltonian and the correspondence principle: they are discussed at length in countless text-books, while it seems unlikely that anybody would embark upon such a special study as that of infra-red spectra without a working knowledge of such matters. On the other hand, the recent verifications for polyatomic gases and the finer points of molecular structure provide very welcome reading; they are presented with a generosity to workers outside Germany which is a pleasure to record.

Solids next receive attention. Here, too, there is a good deal that one is accustomed to find elsewhere, included no doubt for completeness and the reader's convenience, but the story of the gradual unravelling of crystal spectra and the fitting together of fundamentals, overtones, combination tones, and inactive vibrations into a consistent whole is told as only those can tell it who have kept many a night vigil watching the excursions of the spot of light on the scale. The value of the results is great, both for crystal dynamics and sometimes even for the revelation (from the character of the absorption bands) of subtle niceties in crystal structure.

In spite of the high price, spectroscopists and physical chemists should strive to add this volume to their library: they will find in it not only enlightenment but also a certain majesty as of those who return from the harvest, bringing their sheaves with them. F. Ian G. Rawlins.

The Older Rocks and Physiography of Scotland.

Chapters on the Geology of Scotland. By the late Dr. Benjamin Neeve Peach and the late Dr. John Horne. Pp. xvi + 232 + 18 plates. (London: Oxford University Press, 1930.) 10*s*. 6*d*. net.

THE late Dr. B. N. Peach, of the Scottish Geological Survey, is well known to have advocated the view that the Moine gneiss, the most extensive formation in Scotland, is the metamorphosed eastern extension of the Torridon Sandstone. His remarkable personal influence gave that conclusion long currency among his colleagues and inspired a series of ingenious hypotheses to reconcile

it with the facts. This view was, however, never adequately explained in print and remained generally unintelligible. One of its unfortunate consequences was that it prevented the preparation of the work on the geology of Scotland which had been planned by Peach and Horne; for Horne rejected this view of the relation of the Moine and Torridonian rocks and the two authors could not complete their account of the first section of Scottish geology.

After Peach's death Horne resumed work on the book, and prepared five chapters, which give a valuable account of Scottish physiography, and of the petrography, distribution, and history of the investigation of the older rocks. These chapters contain so much inconsistent with Peach's opinions that they are clearly the work of Horne. The sixth and seventh chapters with the accompanying illustrations, Fig. 27 and Plate XVIII., are the work of Peach, and their publication is of importance as they record opinions which have had a great influence on Scottish geology. The arguments for Peach's conclusion that the Moine gneiss is altered Torridon Sandstone are clearly stated by Horne on pp. 199-200 ; and they are followed by three objections which appear unanswerable. In the text (p. 76) reference is made to the occurrence of Moine pebbles in the Torridon conglomerates of Loch Broom; if those pebbles are Moine they are an absolute objection to the Moine and Torridonian being of the same age. The text quotes Teall to the effect that the five pebbles from the Torridonian submitted to him could all be matched by rocks mapped by the Survey as Moine; and a footnote adds that Dr. Horne was of the opinion that they are typical Moine granulites.

In Peach's chapter on Islay some of the sandstones are represented as Torridonian, as if there were no doubt of the fact ; and on the map and the section (Plate XVIII. f. 3) those rocks are marked as Torridonian without the query which Horne insisted on inserting in the Survey maps. The note of interrogation is retained in the block reproduced on p. 204. The identification of these rocks as Torridonian is said on p. 205 to be convincing ; but it has been emphatically rejected by Mr. J. F. N. Green and the reviewer. The upper quartzites of Islay are identified as Cambrian on evidence that appears quite inadequate. Dr. Peach's general views are clearly shown by the Plate XVIII. and are bewildering. The succession includes neither Moine nor Dalradian. The Loch Tay Limestone is represented as the equivalent of the limestone in the slates of Toward, of the Margie Limestone of the Highland Border series and of the fossiliferous Stinchar Limestone (Llandeilo, or Middle Ordovician) near Girvan. The Ben Ledi Grits are claimed as Silurian ; the bulk of the Dalradian as Cambrian, and the Islay Limestone as Torridonian. Dr. Peach expressed such views in conversation, but they appeared vague and variable, and it was difficult to see how they could be reconciled with the general evidence. They are now published explicitly in Plate XVIII.

This definite statement of the opinions which Peach advocated so persuasively renders the volume of historic importance, though the sections which explain his views will probably be regarded ultimately as one of the curiosities of Scottish geology.

J. W. G.

Bibliographical Guides.

Reference Books : a Classified and Annotated Guide to the Principal Works of Reference. Compiled by John Minto. Pp. vii + 356. (London : The Library Association, 1929.) 21*s*.

THE need for a new guide to the literature of books of reference compiled from the point of view of the requirements of the larger libraries in Great Britain is undoubted, and no better choice could have been made in the selection of an editor-in-chief than Mr. Minto, the learned librarian of the Signet Library in Edinburgh. The Brussels decimal system of classification has been adopted as a basis for the classification of the entries. Strict adherence to any system of classification leads to unsatisfactory results, for while a work can be placed only in one class its contents may justify duplication or multiple entry in several. For example, the most complete bibliography of American literature is Sabin's " Bibliotheca Americana ", but it does not appear in this class, though it does elsewhere under works relating to America. This is a case where repetition is justifiable ; but when need for repetition arises from defects in the classification, the better course is to modify the classification by amending the class definition or by transferring the class elsewhere. For example, alchemy is treated in the Brussels classification as a branch of occult philosophy and only one entry appears relating to alchemical MSS. This is a case for class transference—for the bibliography of alchemy and chemistry are often combined. It cannot be too strongly stressed that in preparing guides of the character of this work great freedom is permissible in amending a classification if such amendment tends to clarify the results for the users of the book.

The classes most fully dealt with in the guide are "General Reference", Social Sciences", and "History and Geography". These classes go to confirm Mr. Minto's reputation for solid and scholarly workmanship; but in the classes "Natural Science" and "Useful Arts" Mr. Minto and his coadjutors are clearly out of their depth. The nature of the omissions may be gathered from the following examples. In the class "Chemistry" there is no reference to any of the chemical abstracts or under "Chemical Technology" to the annual reports of the Chemical Society. Under "Mining Engineering" "The Mineral Industry" is omitted, and there are only two entries under the "Bibliography of Agriculture"—one a 44-page pamphlet which is described as representing an important collection! The agriculturists' Bible, "The Experiment Station Record", is not recorded. In turning to the list of contributors mentioned in the preface we see that the advice of librarians of scientific institutions was not thought worth securing. It is regrettable that the Library Association did not insist upon a proper representation of scientific bibliographers upon the advisory panel. The neglect of scientific advice has rendered an otherwise valuable work useless for scientific and technical workers.

Our Bookshelf.

Geologische Karte der Erde. Von Franz Beyschlag. Bearbeitet mit Unterstützung durch die Preussische Geologische Landesanstalt. 1 : 15,000,000. Lieferung 2, enthaltend die Blätter 5, 6, 9, 10. (Berlin: Gebrüder Borntraeger, 1929.) Gesamt-Subskriptionspreis 150 gold marks.

THE second section of this map on the scale of 1 to 15 million, which is being issued by the Prussian Geological Institute under the supervision of Prof. Beyschlag, includes the four sheets of the southern part of the New World. Two of them were easily prepared, for one covers the Central Pacific with part of California, and another the south Pacific and New Zealand. The islands are too small to show their composition by colour, but initials might have been used for the purpose. As it is, islands such as Barbados and those off Brazil are left without any indication of their geology.

The most important of the new sheets is one covering Central and most of South America, and another of Patagonia and the South Atlantic Islands. These two sheets are especially useful. It is not easy to read them fully without the index of colours, which is to be issued with the last section; but they give a clear view of the general structure of South America. South Georgia is unfortunately coloured as Archean, and that mistake is the more remarkable since the fossil which most clearly proves that at least part of the slates in the island are Mesozoic was found by a German doctor, was determined by Pompeckj, and is in the collection of the University of Heidelberg. The uncertainty as to the geology of South America may be realised by comparison of this map with that compiled by Du Toit in 1927. Prof. Beyschlag greatly reduces the area of Lower Mesozoic volcanic rocks in the Upper Parana basin and south-western Brazil, but includes in the lavas a large area near Ascension which Du Toit marks as Devonian, Carboniferous, and Archean. The composition of the Sierra de Tanjil and range to the south of it are also different from Du Toit's map. The maps are an example of clear and beautiful colour printing.

Les Étapes de la physique. Par H. Volkringer. (Encyclopédie Gauthier-Villars.) Pp. ix + 217. (Paris: Gauthier-Villars et Cie, 1929.) 20 francs.

THIS little book of 200 pages is such a good example of the specially French art of popularisation that it is worth examining how the success is obtained. The first point is obvious and clearly attained in the case of M. Volkringer: the author must be a master of his subject. Wherever he gives details of any particular conclusion or experiment, he speaks clearly, as one who has been through that stage and knows it. In the second place, he must be able to select with judgment. This book, slight as it is, gives some enlightening illustrations of all the main stages from Archimedes to Planck and Rutherford. The third point is one on which the French are nearly always more successful than others, one on which the English populariser is apt to feel shy and open to comment. The successful author of such a book must give a certain amount of moralising and what may be thought commonplace generalisation. In this matter M. Volkringer is particularly good; he gives it and it does not appear cheap. Not only his own remarks but apt quotations from greater men punctuate and enliven especially the later pages. "Le succès est le plus puissant toxique." "Le but essentiel de l'industrie est l'adaptation des richesses à la satisfaction les besoins humains." "Tout le secret de sa valeur et son influence [that is, of physics] est dans le fait qu'elle est la science de la mesure."

The book concludes with two short but sufficient chapters on the place of theory in science and the nature of scientific law. The reader gets a glimpse of the philosophy of the subject, but is not immersed in it.

F. S. M.

An Introduction to Organic Chemistry. By Dr. Eric John Holmyard. Pp. xi + 282 + 10 plates. (London: Edward Arnold and Co., 1930.) 4*s.* 6*d.*

DR. HOLMYARD has attempted to arouse interest in organic chemistry among boys and girls in upper forms who have already passed the school certificate examination, by describing the structure and chemical properties of some of the simpler compounds in both the aliphatic and the aromatic series. Stress is laid upon methods used in the purification and analysis of compounds and upon the development of structural formulæ in order to

familiarise the student in the first place with the kind of reasoning by means of which a knowledge of molecular structure may be acquired, and, secondly, with the general properties associated with particular groupings. To each chapter is appended a list of questions to be answered, but no practical details are given for the guidance of beginners. The illustrations include ten full-page plates, six of which are portraits of eminent chemists. The descriptive narrative is occasionally relieved by the introduction of chemical theories, such as Baeyer's strain theory, the theory devised by Le Bel and van't Hoff to interpret the existence of optical isomerism, the polymerisation of formaldehyde to account for the photosynthesis of carbohydrates, and the discussion of the orientation of derivatives of benzene. Notes are also given upon modern commercial processes. The style is clear and the text is not overloaded with detail.

The Art and Religion of Fossil Man. By Prof. G.-H. Luquet. Translated by J. Townsend Russell, Jr. Pp. xiv + 213. (New Haven: Yale University Press; London: Oxford University Press, 1930.) 23*s*. net.

THIS volume is a translation—and it may be said an excellent translation—by Mr. Townsend Russell, of the American School of Archæology in France, of Prof. Luquet's "L'Art et la Religion des Hommes fossiles". M. Luquet is the author of a considerable number of works on the psychology of primitive and prehistoric art; but a wise choice was made in selecting this particular volume for translation into English. Not only is it a valuable description and analysis of the various classes of Palæolithic art, but it is one of the most important contributions to be made by French archæologists to the discussion of the meaning and purpose of that art. M. Luquet is a strong supporter of the view which holds to the disinterested origin of the art of Palæolithic man, though it is recognised that in certain cases a magical element must be admitted. The evidence for a belief in some sort of life after death to be deduced from the burial customs of Palæolithic man is here well marshalled and thoroughly sifted. The illustrations are excellent; they have been selected with discrimination, but at the same time without undue partiality to the line of argument followed by the author.

A Dictionary of Scientific Terms: Pronunciation, Derivation, and Definition of Terms in Biology, Botany, Zoology, Anatomy, Cytology, Embryology, Physiology. By I. F. Henderson and Dr. W. D. Henderson. Second edition, revised. Pp. xi + 352. (Edinburgh and London: Oliver and Boyd, 1929.) 16*s*. net.

THE first edition of this dictionary was published in 1920. Nine years later a second edition appears. Clearly the scientific workers for whom it was compiled have found the book useful.

The present-day student of science is usually ill-educated on the classical side. He often employs the commonest terms in vogue without any serious reflection as to their literal meaning, and his mispronunciations must appal the scholar of Latin and Greek. But if he possess this dictionary and consult it faithfully, there will be less excuse for his blunders.

The second edition contains fifteen hundred new terms, but is no bulkier than its predecessor. Much care and thought must have gone to the recompilation, and the publishers are to be congratulated on their wise decision to allow the whole book to be reset. The authors offer their thanks to those colleagues who have suggested new terms that might be included, and they hope that further suggestions will be forthcoming for future editions.

D. L. M.

The Wilderness of Denali: Explorations of a Hunter-Naturalist in Northern Alaska. By Charles Sheldon. Pp. xxv + 412 + 63 plates. (New York and London: Charles Scribner's Sons, 1930.) 21*s*. net.

THE late Charles Sheldon was a great hunter, and this posthumous work describes the last of his hunting trips, amongst the snows of Denali or Mt. M'Kinley in Alaska. But Sheldon was also a sound observer of Nature, and while the sportsman will be thrilled by his descriptions of difficult stalks after bighorn, moose, and reindeer, the naturalist turns, with some relief, from the tales and pictures of slaughter, to his comments upon the lives of these and other wild animals. Colour protection attracted his attention: snowy owls hunting for mice in the snow were inconspicuous, and motionless ptarmigan were invisible; the markings and coloration of the lynx blended with the rocks; but the colour of the moose rather revealed than concealed it, and the white bighorns were sometimes visible three or four miles away. A sudden plague of field mice and lemmings sprang up in 1907, where none had been seen before; marsh-hawks increased in numbers, and by May of the following year mice were scarce again. There are many such notes scattered throughout the text, but the book is primarily a hunter's account of the pursuit of big game and the habits which had to be explored to make the pursuit fruitful.

The Physiology of Love. By Dr. George M. Katsainos. Pp. vi + 326. (Boston, Mass.: The Author, 176 Huntington Avenue, 1929.) 4 dollars.

DR. KATSAINOS cannot be said to have contributed any great advance to our knowledge in the work under notice. He is somewhat intolerant of the views of others and shows a lack of the critical faculty in his discussion, allowing his emotions to run away with him. To attribute homosexuality to satiety with heterodox sex cravings shows a very superficial knowledge of up-to-date psychopathology, and this is confirmed when we find him attributing *Psychopathia Sexualis* to Freud! One would hesitate to compare dyspepsia to what the author pleases to call dyseros—surely this is a travesty of physiological principles. The book leaves a feeling of dissatisfaction.

Letters to the Editor.

Stellar Structure and the Origin of Stellar Energy.

THE generally accepted theory of the internal conditions in stars, due to Sir A. S. Eddington, depends largely on a special solution of the fundamental equations, and according to this a definite calculable luminosity is associated with a given mass. If this were the only solution of the equations it would conflict, as I have repeatedly shown in recent papers, with the obvious physical considerations which show that we can build up a given mass in equilibrium so as to have an *arbitrary* luminosity (not too large) whatever the assumed physical properties of the material. I have recently noticed that the fundamental equations possess a whole family of solutions, corresponding to arbitrarily assigned luminosity for given mass. These solutions show immediately that Eddington's solution is a special solution and corresponds to an unstable distribution of mass. In the stable distributions the density and temperature tend to very high values as the centre is approached, theoretically becoming infinite if the classical gas laws held to unlimited compressibility.

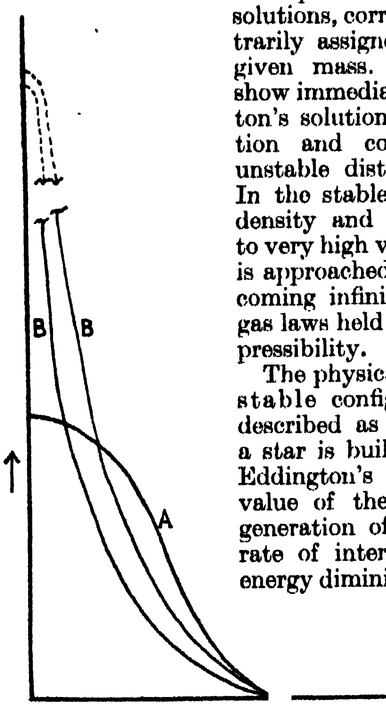

FIG. 1.

The physical properties of the stable configurations can be described as follows. Suppose a star is built up according to Eddington's solution with his value of the rate of internal generation of energy. Let the rate of internal generation of energy diminish ever so slightly. Then the density distribution suffers a remarkable change. The mass suffers an intense concentration towards its centre, the external radius not necessarily being changed. The star tends to precipitate itself at its centre, to crystallise out so to speak, forming a core or nucleus of very dense material. The star tends to generate a kind of ' white-dwarf ' at its centre, surrounded of course by a gaseous distribution of more familiar type; the star is like a yolk in an egg. In this configuration the density and temperature are prevented from assuming infinite values by the failure of the classical gas laws, but they reach values incomparably higher than current estimates. For example, it seems probable (though the following estimates are subject to revision) that the central temperature exceeds 10^{11} degrees, in comparison with the current estimates of the order of 10^7 degrees; and the density may run up to the maximum density of which ionised matter is capable.

The unstable density distribution of Eddington's model (curve A) and the stable density distribution of actual stars (curves B) are indicated roughly in Fig. 1, which is not drawn to scale. It may be mentioned that the instability is of a radically different kind from that discussed by Sir James Jeans. He concluded that perfect-gas stars of Eddington's model were *vibrationally* unstable. In my investigations, the instability of Eddington's model arises from any slight departure of the rate of generation of energy below the critical value found by Eddington. The perfect-gas distribution of my solutions is perfectly stable, but the density necessarily increases until degeneracy or imperfect compressibility takes control.

The consequences amount to a complete revolution in our picture of the internal constitution of the stars. In the intensely hot, intensely dense nucleus, the temperatures and densities are high enough for the transformation of matter into radiation to take place with ease. It is to this nucleus that we must look for the origin of stellar energy, a nucleus the existence of which has previously been unsuspected. The difficulties previously felt as to stellar conditions being sufficiently drastic to permit the evolution of energy largely disappear. Many of the cherished results of current investigations of the interiors of stars must be abandoned; current estimates of central temperature, central density, the current theory of pulsating stars, the current view that high mass necessarily implies high radiation pressure, the supposed method of deducing opacity of stellar material from observed masses and luminosities, the supposed proof of the observed mass-luminosity correlation—all these require serious modification.

The new results are not a speculation. They are derived by taking the observed mass and luminosity of a star, and finding the restrictions these impose on the possible density distributions compatible with this mass and luminosity. By integrating the fundamental equations from the boundary inwards, we are inevitably led to high central temperatures and densities. So long as the classical gas laws persist, the solution is one of the family with a central singularity (infinities in ρ and T), and it is only the ultimate failure of the gas laws which rounds off the distribution with a finite though very large central ρ and T.

Structure of Carbohydrates and their Optical Rotatory Power.

IT would appear from two recent publications by Dr. C. S. Hudson of New York (*J. Amer. Chem. Soc.*, **52**, pp. 1680, 1707; 1930) that the classification of the ring structure of sugars can be decided upon little more evidence than that of the optical rotations which these substances display in a single solvent and for light of one selected wave-length. If this claim could be substantiated, the method might be usefully extended to other groups of compounds and the labours of organic and bio-chemists would be immeasurably simplified.

Dr. Hudson is satisfied, however, with a standard of constitutional proof for the carbohydrates which will not find general acceptance. In no case does he advance evidence which is unequivocal for any sugar, although he attempts to apply definitive formulæ to many. His scheme finds its origin in the assumption that optical rotation is an additive property. At the same time that he is seeking to test this hypothesis he assigns differing structural formulæ to explain the anomalies that arise from it. These are at variance with many of the constitutional formulæ which my co-workers and I have established from a fundamental

study of the behaviour of sugars, although now, after some years of disagreement, he accepts my formula for glucose (NATURE, **116**, 430, Sept. 10, 1925).

Dr. C. S. Hudson has not utilised the means which were open to him to test the validity of his views by direct chemical experiments. The basis on which he develops his argument is the presumed existence, which his statistical methods enable him to detect, of the residue of a new form of mannose (calculated $[\alpha]_D + 77°$) in acetobromo-, chloro-, etc., derivatives of 4-glucosido-mannose, obtainable from cellobiose through cellobial. All the calculations leading to the allocations of structure for the remaining sugars are made to rest upon the assumption that the mannose occurring in the ordinary known form of α-methylmannoside is not present as a residue in this biose. If this foundation for his scheme fails, then the entire superstructure of rival formulæ which he has raised upon it must collapse.

A survey of Dr. Hudson's two recent papers (*v. supra*) has led me to select for this critical test an experimental method which he has tacitly approved: he has accepted and utilised the observation of Fischer that β-methylmaltoside gives rise by enzyme hydrolysis to β-methylglucoside without ring change. Implicit in Dr. Hudson's scheme, therefore, is the expectation that 4-glucosido-α-methylmannoside will yield by enzyme cleavage his hypothetical α-methylmannoside ($[\alpha]_D + 125°$), inasmuch as this is the glycoside of the unknown form of mannose to which he has assigned the 1 : 5-ring.

With my colleague Dr. E. L. Hirst and other co-workers (R. J. W. Reynolds, H. R. L. Streight, H. A. Thomas, J. I. Webb, and Miss M. Plant) I have prepared and investigated the chemical behaviour of both 4-glucosido-α-methylmannoside and 4-galactosido-α-methylmannoside to which the 1 : 4-ring for the mannosido residue cannot apply, since the 4-position in this residue is occupied by the biose link. We have found that these substances are hydrolysed by *emulsin* and yield the ordinary known form of α-methylmannoside ($[\alpha]_D + 79°$) which is the pyranoside (1 : 5-ring). To this pivotal compound Dr. Hudson has assigned the furanoside (1 : 4-ring) structure. It follows that the whole of his rival formulæ for mono- and disaccharides become meaningless.

The above biosides are prepared in the same way as the bioses, namely, from cellobial and lactal by the action of perbenzoic acid, but in the presence of methyl alcohol instead of water. The same 4-glucosido-α-methylmannoside has also been obtained from acetobromo-glucosido-mannose, the reference compound quoted in the statistical scheme.

Had Dr. Hudson tried these experiments it is difficult to see how he could have committed himself to speculations that are at variance with this and with much more chemical evidence which is on record. Moreover, should it be the case that rotational values only are considered the relevant factors, then one may add that the rotations of these biosides and of the corresponding bioses are widely divergent from those required by his system of classification based on epimeric differences with cellobiosides and lactosides and the free sugars. From the optical rotations of these new compounds in the series upon which his case is based, he could have confuted his own thesis and demonstrated by statistical methods the presence of a residue of the ordinary known form, and not the hypothetical form, of methylmannoside or mannose. We showed two years ago that the 'principle of optical superposition' does not apply uniformly throughout the sugar group and that in the mannose, lyxose, rhamnose series the failure was conspicuously evident. The results now summarised are in complete agreement with the sugar formulæ we have established over many years by methylation studies, lactone formation and degradation, and by a comparison of the reaction velocities of glycosides under hydrolysis, and by other direct chemical methods.

Predissociation of the Phosphorus (P_2) Molecule.

IN a recent letter to NATURE, H. H. Van Iddekinge (NATURE, **125**, 858; 1930) communicated the observation that in the emission spectrum of S_2 the same bands occurred as in the absorption spectrum with the exception of those bands which are diffuse in the absorption spectrum (Henri and Teves, NATURE, **114**, 894; 1924; and Rosen, *Z. f. Phys.*, **52**, 16; 1928). According to Van Iddekinge (see also Kronig, *Z. f. Phys.*, **62**, 300; 1930), this is readily explained by the fact that the diffuseness of the band lines is due to a spontaneous dissociation of the molecule in the upper state of these diffuse absorption bands (predissociation) which occurs before radiation can take place; emission of these bands cannot therefore be observed.

When investigating the emission band spectra of the phosphorus (P_2) molecule, I found, about six months ago, an extended band system from 3500 A. to the far ultra-violet, the longer wave-length part of which has already been measured by Geuter (*Z. f. wiss. Phot.*, **5**, 1; 1907). The vibrational structure of this part was easily analysed, whereas the shorter wave-length part is rather difficult because of overlapping of the bands and vibrational perturbations, and has not been yet completely analysed. The analysis of the short wave-length part showed that those bands are present, the ν' of which is below a certain value, say a.[1] In that region there are five strong bands with $\nu' = a$, but no bands at all with $\nu' = a+1$, $a+2$, etc. What is even more significant is that the band lines of the bands with $\nu' = a$ suddenly stop at a certain low value of the rotational quantum number, the last line being very intense; whereas the lines of the bands with $\nu' = a - 1$ stop at a certain higher value of the rotational quantum number, no fall of intensity being evident for lower values of ν'.

The explanation of this phenomenon was rather obvious, and is the same as that independently obtained by Van Iddekinge and Kronig in the case of S_2. Though the absorption spectrum of P_2 vapour has not yet been investigated, it may be assumed as certain that the sudden stop of the bands at the value $\nu' = a$ corresponds to the beginning of bands with diffuse lines in the absorption spectrum at the value $\nu' = a+1$. These absorption bands, however, lie in the far ultra-violet, because, as always for absorption bands, ν'' will be small, whereas the emission bands in question lie on the other branch of the Franck-Condon parabola, that is, high values of ν'', and therefore at longer wave-length.

In all cases of diffuse molecular *absorption* spectra observed hitherto, diffuseness sets in at a certain band, but it has not been previously observed that it sets in at a certain line of a band. It seems, however, to be so in the case of P_2 as shown by the fact of the drop of intensity in the *emission* bands discussed above. This sharpness of the limit of predissociation seems to be rather significant. Therefore, it would be highly interesting to investigate the absorption spectrum of the P_2 molecule, and it is hoped to do that later.

Recently Grundström and Hulthén (NATURE, **125**, 634; 1930), Stenvinkel (*Z. f. Phys.*, **62**, 201; 1930) and Kronig (*Z. f. Phys.*, **62**, 300; 1930) have tried to explain several examples of the breaking off of emission bands of hydride molecules by predissociation. It seems to me, however, that in most of these cases the available data are not sufficient definitely to exclude Oldenberg's explanation by rotational instability (*Z. f. Phys.*, **56**, 563; 1929), because the energies of dissociation of all electronic states involved are very small and, as nearly always in hydride spectra, cannot be determined accurately, if at all. In the case of P_2, however, which seems to be the first molecule other than a hydride showing this breaking off of band lines, Oldenberg's explanation can be definitely excluded, because the last observed vibrational frequency is 424·5 cm.$^{-1}$ and the decrease for successive vibrational quantums is 4·7 cm.$^{-1}$ as shown by more than six definitely located levels.

The absolute value of the predissociation limit thus found cannot be given very accurately for the moment, because the origin of the band system has not yet been found. A rough value of 45,000 cm.[1] (5·5 volts) may, however, be given. This represents an upper limit for the heat of dissociation of the P_2 molecule (cf. G. Herzberg, *Z. f. Phys.*, **61**, 604; 1930).

[1] The absolute value of *a* cannot be given, because the origin of the band system has not yet been found.

Distribution of Growth Activity in *Eupagurus*.

INVESTIGATIONS on the relative growth of parts in the common hermit crab, *Eupagurus prideauxi*, which will shortly be published *in extenso* in *Roux's Archiv*, reveal some interesting facts of general significance.

In previous communications [1] it has been pointed out that when organs or regions are growing at rates different from that of the body as a whole, there exists in them a *gradient* of growth-activity, with a maximum point (*growth-centre*) from which the intensity of growth decreases in both directions. In the case of markedly heterogonic crustacean limbs, this growth-centre has always been the penultimate segment (propus). This is confirmed for the male right chela of *Eupagurus*, which is heterogonic in later stages. But in earlier life this limb is growing only slightly faster than the body; and in this phase the growth-centre is two segments more proximal, in the merus.

The following table gives the percentage increases of the various segments of the right chela, and that of the thorax-length as standard for the body, in young and old males.

	Thorax.	Ischius.	Merus.	Carpus.	Propus.	Dactylus.
Small males (thorax length, 9·0-11·36 mm.)	26·6	28·5	*40·0*	35·0	30·0	27·5
Large males (thorax length, 12·2-13·3 mm.)	0·5	13·0	16·4	16·3	*16·6*	14·5

The interesting point is that the slower-growing left chela and the two long walking legs (pereiopods 2 and 3) show, throughout the size-range examined, a gradient similar to that of the right chela in its early stages, with high point in the merus. Thus different constructions and different rates of relative growth of appendages demand that the main increase of growth shall be in different regions; but in both cases increased growth proceeds by means of growth-gradients culminating in a high point or growth-centre.

It then appears that we can extend this conception of growth-gradients from the growth of single appendages to that of the body as a whole. Fig. 1 shows the percentage increase in length of the various appendages (or conveniently measurable portions thereof) in both males and females, for a percentage increase in thorax-length of 48·2 per cent, for specimens between 9 and 12 mm. thorax-length. The graded effect is well shown on the left side of the male curve. Small eyestalks and maxillipeds, lengthy 2nd and 3rd pereiopods, short 4th and 5th pereiopods —all, when considered in regard to their growth-

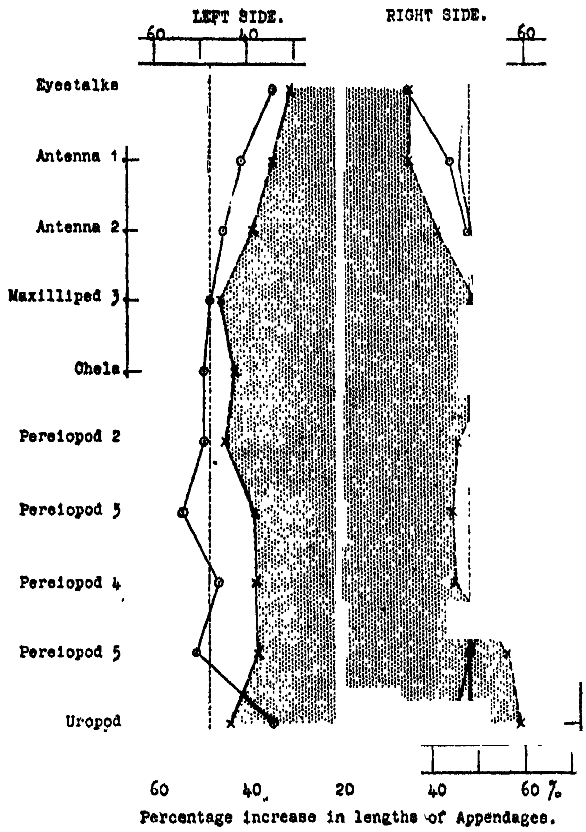

FIG. 1.—⊙——⊙, male; ×----×, female (stippled). Vertical dotted line represents percentage increase of thorax length.

rate instead of their absolute size, fall into a single gradient-system with high point at pereiopod 3. The male right side shows a similar gradient, but interrupted locally by the strong heterogony of the right chela. The female appendages show a different distribution of growth-intensity—everywhere save posteriorly this is less than the male's, and has two high points, one between maxilliped and 2nd pereiopod, the other in the abdomen.

The graded effect is shown also as regards the degree of asymmetry, which may be measured as the percentage ratio of the lengths of left-hand to right-hand appendages. Fig. 2, which illustrates this, requires little comment. Note that the greater right-handedness of the male thorax, culminating in the chela, causes males to remain predominantly right-handed for a third of a segment farther down the body than is the case in females.

These facts would indicate that what we may loosely call 'growth-potential' is distributed in an orderly fashion through the animal body, in a series

of growth-gradients, which are of varying shape and steepness, and apparently interact with one another as illustrated by the fact (*loc. cit.* p. 910) that an active

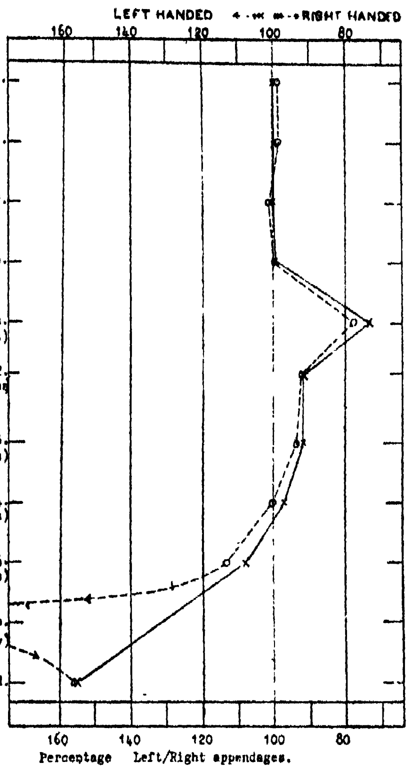

FIG. 2 — ×——×, male; ⊙- - - -⊙, female.

growth-centre in one appendage is correlated with increased growth-activity in limbs immediately posterior to it, decreased growth-activity in those immediately anterior.

Virus Disease of the Potato: Streak.

THE term 'streak' has been applied to a diseased condition of the potato in which the leaf and stem tissues become to a greater or lesser extent involved in a necrotic process. The condition was first described as a separate disease by Atanasoff under the name of 'stipple streak', and has since received considerable attention from the clinical point of view from Quanjer and others. In this Institute I have shown how 'streak' may be but an alternative symptom of another disease, namely, crinkle *A*; and my colleague, Dr. Kenneth Smith, that it may assume a somewhat similar relation to ringspot disease of tobacco. In the former, the change from crinkle to streak is induced by varietal susceptibility; in the latter, by *passage* of an original potato mosaic virus through tobacco before being used as an inoculum to reinfect the healthy potato. Streak is clearly a clinical picture which may be reproduced by different agents.

In pursuance of the task of obtaining virus-free stocks, I have frequently been brought up against the problem of the apparently healthy virus carrier, and have dealt with the question in some detail in two recent papers.[1] This year's work has given me good reason to believe that there may be at least two distinct viruses which produce streak, and, as in the case of the two distinct crinkles, namely, crinkle *A* and paracrinkle, they are to be distinguished by their varietal reactions.

The variety Di Vernon is only with some difficulty to be obtained free from all external signs of virus disease. Two out of three such apparently healthy and very vigorous stocks in my possession, when grafted to healthy Arran Victory plants, produced in them but a mild mosaic, but when grafted to healthy President plants, a violent and lethal streak. Further, if the mosaic-affected Arran Victory be grafted to President, the latter succumbs to acute streak in the same way as did those grafted directly from the Di Vernon.

Uptodate has long been known to carry a latent streak, though it itself may appear to be in the best of health. I have tested out a great many units of Uptodate from the very best stocks obtainable in Scotland and Ireland, and have, with one doubtful exception, found them all to be carriers of virus disease. Now the streak which Uptodate may carry reacts differently from that carried by Di Vernon: here both healthy test plants, Arran Victory and President, develop a moderate and generally non-lethal streak. However, the Arran Victory usually suffers more severely than does the President—the reverse of what was found with Di Vernon streak.

To the Uptodate class of streak reaction belongs that found in two more carriers, namely, Kerr's Pink and Majestic. In the latter variety, streak carriers seem rather rare; in the former the matter is complicated by the fact that whilst all Kerr's Pink stocks (in my opinion) are carriers, the virus they carry is clearly depressed in virulence by its sojourn in Kerr's Pink, and it is only rarely that its reaction on grafting to other varieties is in terms of streak.

A corresponding difference of reaction is found when Daturas are inoculated with the two types of streak. The Di Vernon carriers produce no reaction in Datura; the Uptodate and Kerr's Pink carriers, on the other hand, cause a reaction identical with that following inoculation with crinkle *A*.

As it seems wisest to discriminate between the viruses of the potato by their reaction in standard healthy varieties rather than by their clinical appearance in any one variety, I would suggest that the virus which produces streak in both healthy Arran Victory and President and may be latent in Uptodate, Kerr's Pink, and Majestic, be termed streak *A*; and that which may be latent in Di Vernon, produces a streak in healthy President but fails to do so in healthy Arran Victory, be called streak *B*. Such a system of nomenclature leaves room for the identification of other streaks, evidence for which is now accumulating in our Institute.

REDCLIFFE N. SALAMAN (Director).

Transmission of Potato Leaf Roll.

IN his letter in NATURE of July 19, p. 96, Dr. Kenneth Smith appears to be under the impression that I 'deplore' the importance attached by virus workers to *Myzus persicæ* as a vector of potato leaf roll. The importance of this insect in this respect was not called into question in my letter in NATURE of June 28, but rather "the growing tendency . . . to regard the relation of *M. persicæ* to leaf roll transmission as specific and unique". Dr. Smith reminds me that in May 1929 he expressed the opinion that *M. persicæ* is probably not the only carrier of leaf roll.

In his latest publication, however, (*Jour. Min. Agric.*, June 1930, p. 227) he emphasises the similarity between leaf roll transmission by *M. persicæ* and other plant virus diseases in which it is said that one, and only one, insect is capable of carrying the virus. *M. persicæ*, he states, has a marked affinity for several potato viruses, especially for the leaf roll virus, whilst "other insects such as capsid bugs, leaf-hoppers, and the *remaining species of aphides*, have failed to transmit the diseases". Here is evidence of the growing tendency referred to in the mind of at least one virus worker. Although proof is lacking, I think it quite probable that *M. persicæ* bears a more subtle relationship to leaf roll transmission than that of a mere mechanical agent, but this relationship, whatever it may be, would appear to be shared to some extent by *M. circumflexus*. So far from minimising the importance of *M. persicæ* in leaf roll transmission, in my letter I attributed little or no importance to *M. circumflexus* as an active agent in spreading virus diseases.

Dr. Smith disagrees with my suggestion that *M. circumflexus* should prove of value in virus transmission studies, apparently because (1) it is not uncommon for the characteristic dorsal markings to be absent from specimens of *M. circumflexus*, and (2) this species is stated to be a poor transmitter of mosaic and to possess, in its saliva, a toxin which produces a 'false mosaic' in Solanaceous plants, including the potato. With regard to the first objection, it is obvious that the absence of the dorsal bands in occasional adults makes the task of detecting such apterous females of this species uncertain, but surely not more so than in other unmarked species, for example, *M. persicæ*. Exceptional individuals need not be selected for use in artificial infestations, and any initial error in diagnosis can thus be obviated. The appearance of unmarked adults in the cages will, at least, raise a suspicion of admixture of species in the mind of the worker and will induce caution in interpreting results.

The suggestion that *M. circumflexus* possesses a toxin in its saliva is, if substantiated, of great importance and marks a definite advance in our knowledge of viruses. It will of course restrict the use of this species to special aspects of mosaic transmission, but it is difficult to see in what way the power to produce a false mosaic will impair the value of *M. circumflexus* in *leaf roll* transmission studies; and these studies, after all, formed the subject matter of my first letter. Flint Implements of Upper Palæolithic Age from Yorkshire.

IN regard to Mr. Bromehead's objection (NATURE, July 5, p. 13) to my letter in the issue of June 7, p. 858, it might perhaps dispel any misunderstanding that may have arisen in connexion with the same if I say that Messrs. Dewey and Bromehead, after they had investigated the sites under consideration last May, were unanimous in relegating Lamplugh's "Late Glacial Boulder Clay" deposit of Danes' Dyke to Late Pleistocene times, though, I was given to understand, they regarded it as a hill-wash formed under cold conditions rather than a boulder clay. In accordance with these opinions, Mr. Dewey afterwards supplied me with the wording for par. 2 of my letter in NATURE of June 7 as representing both his and Mr. Bromehead's views concerning the age of the deposit they had been asked to examine.

As space cannot be spared in NATURE for a full statement of the facts, I have given the details in a letter which I am circulating privately, and I am content to leave these to speak for themselves.

J. P. T. BURCHELL.

30 Southwick Street,
Hyde Park, W.2, July 7.

IN answer to Mr. Burchell, it is inaccurate to say that I relegated Lamplugh's "Late Glacial Boulder Clay" deposit to Late Pleistocene times, since Lamplugh nowhere described the flint-bearing deposit by those words. In his paper on the Drifts of Flamborough Head (*Quart. Jour. Geol. Soc.*, vol. 47, pp. 384-431; 1891) he shows the deposit in question in only one of his fifteen sections, that at Danes' Dyke; he describes it as "a few feet of loamy stuff resembling a weathered Boulder Clay" and as "stony earth like weathered Boulder Clay", and in a generalised table includes it under the heading "Late Glacial Gravels, Brickearth, and Boulder Clay". In all other sections Lamplugh ignores this deposit; he also omits to show any soil or subsoil. I personally am convinced that if Lamplugh were with us to-day he would class Mr. Burchell's deposit under some such heading, or use the more expressive Yorkshire term, 'muck'. In the memoir on Holderness, Clement Reid definitely classes the bed at Kelsey Hill, Burstwick, as Post-Glacial.

The report by Mr. Dewey and myself to the Director of the Geological Survey was made as favourable to Mr. Burchell's views as our opinions allowed. In his letter published in NATURE of June 7, Mr. Burchell anticipated this report; he quoted the only words in any way favourable to his view and omitted to say that on the main question, whether the 'implements' are overlain by Boulder Clay, our decision was unfavourable. In his present letter he takes a similar course with regard to Lamplugh's published paper. I am therefore glad to know that his "full statement of the facts" has been circulated privately.

The Second World Power Conference at Berlin.

IN his article in NATURE of July 19 on the Second Plenary World Power Conference in Berlin, Mr. H. Quigley has presented the results of the meeting in a somewhat wrong perspective. As a matter of fact, the constitution of the World Power Conference renders it almost impossible for immediate action to be taken such as he would suggest. The position is really as follows: a number of resolutions, some of which bear very directly upon the work of the Conference as a permanent organisation, were passed during the technical sessions, but in accordance with our unvarying practice, none of these resolutions was endorsed by the International Executive Council this year. They will be circulated to all the national committees, will be examined by a special sub-committee, and will come up for consideration and appropriate action at the next meeting of the Council, to be held in London at the time of the Faraday celebrations in September 1931. In other words, no exceptional treatment was accorded to the resolutions passed during the technical sessions this year.

On the other hand, the International Executive Council, of its own motion, took a number of decisions of first-rate importance concerning the future "work of the Conference". Specific proposals were put forward by the Central Office or by national com-

mittees for issuing a statistical year book based upon standard forms for the collection of data relating to the power resources of the world upon a comparative basis, in connexion with which a mass of preliminary work has been accomplished during the past three years. Arrangements were made for the publication of selected annotated bibliographies upon a uniform system. The possibility of issuing a periodical Central Office bulletin was explored. Lastly, a special sub-committee was appointed for the very purpose or re-examining the activities and organisation of the World Power Conference. The following passage occurs in the Report presented on behalf of the International Executive Council at the closing meeting of the Berlin Conference: "The International Executive Council has set up on the basis of some definite proposals put before it, a Sub-Committee which is to submit to its next meeting in 1931, after consultation with the National Committees, certain proposals promoting the rational development and increasing the usefulness of the World Power Conference".

Ultra-Violet Light and Atmospheric Pollution.

THERE are so few manufacturing towns where observations have been taken of the incidence of ultra-violet light that Mr. Bower's results which are given in a letter to NATURE of July 12, p. 59, are very welcome. On the average of three years he finds that Sunday is a day with 12 per cent more ultra-violet light than the average of all days of the week. In Rochdale, observations in 1929 show Sunday also to be a day of more ultra-violet light than the average of all days of the week, and the excess is 12 per cent, which is in exact agreement with Mr. Bower's results for Huddersfield.

Now in Rochdale a daily record has been kept of the soot-fall, and it is found that the number of particles deposited on Sundays is 29 per cent *less* than the average of all days, and there is therefore direct evidence that reduction in soot-fall and increase of ultra-violet radiation occur together. The falling off of deposited particles concurrently with the increase of ultra-violet rays which is found on passing from town to country is evidence in the same direction. There can be little doubt that factory smoke in manufacturing towns cuts off much of the valuable light of the sun.

By the kindness of Sir Leonard Hill I have been supplied with the daily observations of ultra-violet light in 1929 at London, Cardiff, Lowestoft, and Ventnor, and I have worked out the Sunday and week-day values. Confining attention to Lowestoft and Ventnor, two seaside resorts free from factory smoke, we have as the combined percentage result:

Sun.	Mon.	Tues.	Wed.	Thurs.	Fri.	Sat.	Average.
97	100	104	100	104	101	94	100

Here Saturday and Sunday have less ultra-violet light than week-days. Contrast with this the combined result for Huddersfield and Rochdale, which is as follows:

Sun.	Mon.	Tues.	Wed.	Thurs.	Fri.	Sat.	Average.
112	99	99	94	94	99	103	100

It seems reasonable to suppose that at the seaside resorts the week-end activities increase the pollution of the air, and this is the more probable as the diminution on Saturday and Sunday of ultra-violet radiation is mainly in evidence in the summer—the holiday time.

Thus the measurement of ultra-violet light, in addition to the value attached to it by medical men, will probably provide a new and it may be a delicate test for atmospheric pollution.

Rochdale, July 22.

Atomic Diameters of the Rare Gases.

IN our note on the crystal structure of krypton in NATURE of June 14, p. 889, we gave the ratios of the distance of nearest neighbours in the crystal lattice to the atomic diameter deduced from viscosity measurements for neon, argon, krypton, and xenon, as 1·35, 1·29, 1·22, and 1·23 respectively.

We took the values of the atomic diameters calculated by Herzfeld from measurements by Rankine ("Handbuch der Physik", vol. 22). We owe to Prof. Rankine himself the information that these values must be considered to be too large, as Herzfeld made use of the value of Sutherland's constant given in the Landolt-Börnstein Tables of 1923, which value is too low (cf. Rankine and Smith, *Phil. Mag.*, **42**, 601; 1921). Using the values of the atomic diameters 2·30, 2·87, 3·10, and 3·41 A. calculated by Prof. Rankine, the ratios become 1·39, 1·34, 1·28, and 1·28.

The value for krypton is lower than would be expected; this may perhaps be explained by the fact that its structure was investigated by us at a relatively much lower temperature compared with the Debye characteristic temperature than was the case for the others. Indeed, Natta and Nasini's value of the distance of nearest neighbours at the temperature of liquid nitrogen leads to 1·32 for krypton.

Gamma Rays of Potassium.

Two years ago W. Kolhörster published a short paper [1] on the gamma rays of potassium, which he ascertained partly by measurements in the Stassfurt mines and partly by analysing the radiation of a greater quantity of sylvin supplied by Messrs. C. A. F. Kahlbaum.

In our Institute ionisation measurements have been carried out using a large ionisation chamber of a capacity of 125 litres and about 120 kgm. of chloride of potassium. Kolhörster's results have been confirmed so far that chloride of potassium really emits penetrating radiation, the intensity of which is proportional to the quantity of potassium. The radiation is complex and consists of at least two groups of gamma rays. By absorption of these rays in lead 0·5-4·0 cm. thick an absorption coefficient for the first group of rays has been found of approximately the same order as in the case of the gamma rays of radium, whereas the second group is about twice as penetrating as the gamma rays of radium. On the other hand, the intensity of the gamma rays of potassium is much lower than that which would correspond to its period of $T = 10^{12}$ years, if we assume that every beta ray of potassium is followed by one gamma ray. A detailed description of the work done will be published next autumn.

Some Scientific Instrument Makers of the 18th Century.*

By Robert S. Whipple.

Although numerous references are found in early British manuscripts to instruments of an elementary kind, chiefly for the determination of time or position, there is little evidence that before the sixteenth century scientific instrument making as a craft had obtained a position of any importance in Great Britain. The demand for instruments to assist navigation became more insistent as new lands were discovered and the length of the voyages increased.

Gradually the professional scientific instrument maker came into existence, two of the more distinguished being Humphrey Cole, the maker of the astrolabe used by Sir Francis Drake, and Elias Allen, the maker of Oughtred's double horizontal dial. In a book by Oughtred dated 1632 describing the double horizontal dial it is stated that it is printed for Elias Allen, "Maker of these and all other Mathematical Instruments and are to be sold at his Shop over against St. Clements Church without Temple-barr".

With the discovery of the telescope in 1608, and its development by Galileo in the following years, a great impetus was given to the instrument-making industry. Although Gregory and Newton propounded the reflecting telescopes known by their names in 1663 and 1666, they were unable to find makers capable of developing their ideas. Newton made his own instruments, but it was not until about 1730 that John Short of Edinburgh succeeded in making a Gregorian telescope.

The latter half of the seventeenth century was a great period of scientific development. Experimental science, under its leaders Boyle, Hooke, Newton, and others, created a demand for scientific instruments which could only be satisfied by skilled craftsmen. The work of Hooke and Leeuwenhoek did much to develop the microscope and to direct attention to the possibilities of the instrument. Fortunately an instrument made about 1670 and somewhat similar in its details to that described and illustrated in Hooke's "Micrographia" (1665) has been preserved. The evidence is, I think, convincing that this instrument was made by Christopher Cocks, the well-known telescope maker, who lived in Long Acre, and of whose telescopes there are at least three in existence. It is known that in March 1672 Cocks was ordered to make a four or five foot Newtonian reflecting telescope, but the instrument was not successful. About 1680 he was admitted a freeman of the Spectacle Makers' Company.

Owing to the publication of the "Micrographia", with its description of Hooke's microscope, great interest was created in microscopical work, and a demand arose for microscopes. Owing to the high quality of the optical and mechanical work the English microscope won a high reputation.

The greatest of the English instrument makers who bridge the seventeenth and eighteenth Centuries is undoubtedly John Marshall. Nothing is known of his early life, but part of a diary recently discovered in the British Museum by Mr. H. W. Robinson, by whose courtesy I am able to publish an extract, has thrown an interesting sidelight upon Marshall's career. The record covers five years of Hooke's life, 1688 to 1693—with the exception of some few months—and was thought to be the diary of James Pettiver, an apothecary friend of Hooke. Mr. Robinson has been able to prove that it was written by Hooke. The following is an extract, December 14, 1688: "One John Marshall who told me he was Dunning apprentice and now worked at turning at the 3 keys in Ivy Lane came to shew me some microscopes of his own making he told me Mr. Boyle had bought such of him". He appears to have set up later at the sign of the Gun as a maker of spectacles and microscopes, and there is little doubt that the microscopes were of the Hooke type. By 1690 he had built up a large business, and had introduced a new method of grinding lenses on brass tools. Marshall's double microscope was undoubtedly the greatest advance made in microscope construction for many years. The instrument was fitted with coarse and fine focusing adjustments, and for the first time the limb which carried the eyepiece, the object glass, and the object, formed one complete system which could be inclined as one unit. All the features are retained in the modern instrument.

The first outstanding English instrument maker in the eighteenth century is undoubtedly Benjamin Martin, a man who, so far as is known, was not apprenticed to the trade. He was born at Worplesdon, Surrey, in 1704, and began life as a ploughboy, later becoming a teacher of the 'three R's' at Guildford. He devoted his spare time to the study of mathematics. A legacy of £500 relieved him from the necessity of teaching, and enabled him to travel and lecture. He appears to have assisted at the lectures given by Dr. J. T. Desaguliers, which were eagerly attended by the fashionable world and were illustrated by experiments. Horne, afterwards president of Magdalen College, Oxford, sarcastically remarked that Ben Martin "who having attended Dr. Desaguliers' fine raree gallantry show for some years in the capacity of a turnspit, has it seems, taken it into his head to set up for a philosopher". This is a hit at Martin's literary efforts, because he proceeded to publish a large number of text-books dealing with a great range of subjects. When it is considered that Martin was a self-educated man, the extent and thoroughness of his knowledge, as shown in his publications, are remarkable. He appears to have lived for some time at Chichester, where he kept a school, and also wrote several elementary text-books and pamphlets describing scientific instruments. There is little doubt that he commenced to make scientific

* From a Friday evening discourse delivered at the Royal Institution on May 23.

instruments in Chichester, not improbably being asked by the readers of his books where it would be possible to obtain the instruments mentioned.

About 1750 Martin moved to London to a house in Fleet Street, three doors below Crane Court, where he became famous as a scientific instrument and spectacle maker at the sign of "Hadley's Quadrant and Visual Glasses". Martin was essentially a teacher, and continued to write after he had made his home in London. The books impress one with the care he takes to make every individual step in an explanation clear, and with the detailed drawings and references with which he explains the construction and use of an instrument. This is strikingly illustrated in his description of the various orreries he constructed. The orrery was almost the latest scientific novelty, and Martin appears to have been much impressed with the educational possibilities of the instrument. In his "Young Gentleman and Lady's Philosophy in a continued survey of the works of Nature and Art"—a book which had a great vogue—he uses planetaria to describe the difference between the Ptolemaic and Copernican systems, and the phenomena of eclipses, etc. He was evidently prepared to supply either form of planetarium to suit his customers' wishes. In one of his tracts published in 1771, "The Description and Use of an Orrery of a new Construction", he gives full details of the capabilities of the instrument, and also "the theory of calculations for the wheel-work of an orrery to the most extreme Degree of Accuracy". The prices of the instruments ranged from £12 12*s.* upwards, depending on the number of bodies demonstrated, and the accuracy of their movements, or as Martin himself states "proportional to the work". That Martin must have continued to lecture until late in life is shown by the fact that the apparatus made is adapted to show "all the Phaenomena [*sic*] of the Transits of Mercury and Venus over the Face of the Sun such as I shewed in Public to Thousands on the late memorable instance of 1769".

In 1740 Martin published a useful text-book on optics, "A New and Compendious System of Optics", and in many other writings took immense trouble to explain optical systems and instruments. His microscopes and especially his cabinets containing two or three instruments of various types were much sought after, and still remain as examples of first-class workmanship and ingenuity. There is little doubt that he invented the drum type of microscope (see Fig. 1) which had a great vogue and is still made in large numbers on the Continent. If the invention of the glass micrometer as applied to a microscope was not actually due to him he was undoubtedly one of the first to employ it. He was also one of the first to apply rack and pinion focusing adjustments to the compound microscope, and to fit inclining movements to the pillar carrying the stage and mirror.

It is a cause of wonder to me how Martin was able to produce such a large number of books. The "Dictionary of National Biography" mentions thirty-one, although some of them are only leaflets. Many of his books passed through several editions, and at least one was translated into French. They undoubtedly helped to popularise science and to create an interest in scientific instruments. Shortly before his death at the age of seventy-seven, he took his son into partnership, and unaware of the state of his affairs was adjudged bankrupt. He thereupon attempted suicide, and the wound hastened his death. His valuable collection of fossils and curiosities was sold by public auction

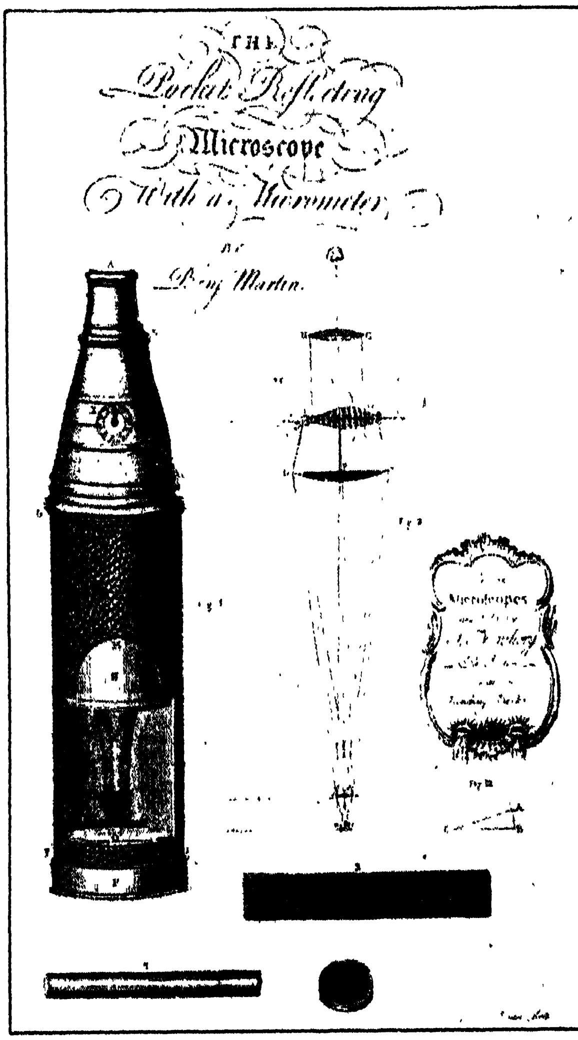

FIG. 1.—Microscope, drum type, by Benjamin Martin.

for a trifling sum—a tragic ending to a more than usually successful career.

George Adams, the elder, perhaps the greatest of English scientific instrument makers, was born about 1704. It is known that he was apprenticed in 1718, and that he was established in business on his own account at Tycho Brahe's Head in Fleet Street in 1735. It is also known that he was making instruments for the East India Company in 1735–36. He obtained a world-wide reputation as a maker of globes. In 1766 he published the first edition of his book "A Treatise describing and explaining the construction and use of new celestial and terrestrial globes". Dr. Samuel Johnson, the lexicographer, wrote the dedication to the King, and for so doing received a present

of "very curious meteorological instruments of a new and ingenuous construction". The book had a great vogue, passing through thirty editions.

Adams was essentially a mechanic and delighted in good workmanship. There can be little doubt, I think, that the microscope was his favourite instrument, and he developed several types of it. In 1746 he published his "Micrographia Illustrata: or The Knowledge of the Microscope explained in several new inventions etc.". The preface to the "Micrographia Illustrata" emphasises the religious side of Adams's character, and also shows that he must have had the artistic and poetic temperament highly developed. The first edition of the book contained an account of a "New Universal Microscope" which was made to an entirely original design, the object being, as Adams states, "to have a Microscope which would be Portable and Universal, that is to say, ONE ONLY INSTRUMENT, by which all Sorts of minute Objects might be observ'd". The microscope was provided with six single lenses of different foci with a common focusing screw. Adams remarked of this focusing screw that it "is to be turned as your hands and arms are resting on the table, which is a conveniency to be met with in no other Microscope". A second edition of the "Micrographia Illustrata" appeared in 1747, and a fourth in 1771. Despite exhaustive researches it has not been possible to find a copy of the third edition—if it were ever published.

The fourth edition commences with a description of the variable microscope of which Adams was evidently very proud. He states that "We owe the construction of the Variable Microscope to the ingenuity and generosity of a noble person", and we know that the "noble person" was the Earl of Bute. By having a compound eye lens and by introducing an auxiliary lens placed some distance above the objective the definition was improved. Adams also introduced the method of screwing two or three objective lenses one on top of the other. By drawing up the eyepiece relative to the object glass the power of the combination could be altered and hence the name "variable". Adams, in common with Martin and other makers of the period, developed the solar microscope with the large mirror projecting out of the window, by means of which brilliant illumination could be obtained, and magnified images of the object projected on to a screen.

(*To be continued.*)

Biometry and Evolution.

WHEN an entirely novel and revolutionary view is put forward by a man of scientific eminence, the critic must endeavour to form a decision between two alternatives, for both of which he must necessarily be, to some extent, unprepared. Either a scientific discovery has been made of such a magnitude as to subvert a whole body of apparently well-founded opinion, or, what is more disturbing still, some incredible error has frustrated in its effect all that we might hope from trained ability, industry, and patient thought. We owe it to science to keep this latter possibility in view, whatever may be the weight of authority which is in the balance.

Under the title of "On a New Theory of Progressive Evolution" (*Annals of Eugenics*, vol. 4, pp. 1-40) Prof. Karl Pearson puts forward a theory which, as he realises, will be difficult to bring home to the biologist. In his own words, "The intensity of heredity is such that with isolation and inbreeding any individual characteristic, or deviation from racial type, will be gradually emphasised and become a factor of progressive evolution. Thus all organisms if isolated are in a constant state of evolution, and it is only interbreeding and the selective action of environment which preserve a type. In other words, natural selection controls evolution, but the progressive urge is provided by heredity itself."

It is obvious that in this statement Prof. Pearson is using the word 'heredity' in a sense somewhat different from its popular and biological meaning. There is, however, little occasion for surprise in this, for those familiar with his writings will know that the term is used to cover all the statistical relationships between the measurements of related individuals. What is asserted is that these relationships require that when a group of individuals, differing, however little, from the mean of their species, is isolated, so that they and their descendants interbreed without further selection, then the mean of this isolated population will continue to depart further and further from the mean of the population from which their ancestors were originally selected. A diagram on p. 10 of the monograph shows this process in detail. The first generation following isolation shows, indeed, some regression towards the mean of the original population and differs from it by only about 70 per cent as much as its parents. In the second generation, however, the mean has progressed to nearly 95 per cent and, thereafter, the successive means actually exceed that of the foundation stock, and increase so rapidly that by the eighth generation the deviation is nearly seven times as great as it was at first.

For the formulæ from which these astonishing results were derived recourse should be had to the mathematical appendix, where, on p. 23, we find that they are the result of applying a certain recurrence formula, based upon a system of formulæ for the correlations between the averages of different groups of ancestors of the same individual; the numerical values come ultimately from three correlations found in human stature, namely, parental correlation 0·50625, fraternal correlation 0·53367, and marital correlation 0·2804.

Prof. Pearson has been content to apply his recurrence formula numerically, but it is capable of algebraic solution. It appears that the deviation

after n generations will be M times the deviation of the foundation stock, if M is given by the formula

$$M = \frac{a}{b} \cdot \frac{(1/b-1)!}{\{(1+a)/b-1\}!} \cdot \frac{\{n-2+(1+a)/b\}!}{(n-1+1/b)!} \cdot 2^{n/2}.$$

The formula involves two numerical constants, a and b, for which Prof. Pearson's values are $a = 0{\cdot}494155$, $b = 0{\cdot}55916$. It will be noticed that the progressive evolution deduced from this method depends upon two factors, of which one, $2^{n/2}$, representing a doubling in every two generations, has perhaps been introduced through an incomplete allowance for the fact that, with bi-parental reproduction, each individual has 2^n ancestors of the nth degree. The remaining factor

$$\frac{\{n-2+(1+a)/b\}!}{(n-1+1/b)!}$$

increases progressively only when a exceeds b. This is not so with Prof. Pearson's values, which, if the factor $2^{n/2}$ were removed, would thus give a progressive decrease, less rapid than, but equally foreign to biological reasoning as, the progressive increase shown by his values. This trouble disappears, however, if a is equal to b, as it may well be, if the relatively small difference between Prof. Pearson's values be ascribed partly to sampling errors in the original data, and partly to a second but slighter inexactitude in the process of reasoning by which the infinite series of ancestral correlations is deduced from the three correlations actually observed.

The thesis thus derived theoretically is supported both by the author's own experiments and by a reinterpretation of the experiments of others. Although Prof. Pearson writes strongly, when genetical concepts come into view, it may be doubted if he would much rely upon these two sources of information, if his theoretical deductions were once shaken. The personal observations cited are indeed somewhat meagre. It appears that an experiment started twenty-five years ago with the crossing of toy Pomeranians and Pekinese has been continued since with much inbreeding; the experimenter has "been a good deal puzzled of recent years by a progressive tendency to lengthen the leg". The experiment was not concerned with leg length. "But this very ungainly length of leg has been continually obtruding itself, although I have paid no regard to it in mating." Unfortunately, no measurements were taken, and the skeletons were not preserved, so that it is largely a matter of taste whether or not we share the author's deduction: "Given isolation and inbreeding, say from a single isolated pair, then if both members of the pair differ by excess or defect from type—and this by however small a quantity—their offspring by continual inbreeding will progress for this character, and therefore for all correlated characters. This is the idea that came to me from the long-leg progress of my dogs."

The reviewer feels a particular regret that the data on this case are not fuller, for about eighteen months ago he happened to write, in connexion with the biometric effects of recent selection, "Equally, when, as in the development of toy breeds of dogs, selection has favoured diminished size, we should expect to find an excess of recessives tending to increase the average dimensions".

R. A. FISHER

Food Preservation.

THE practical value of the numerous researches carried out under the auspices of the Food Investigation Board is clearly shown on perusal of the Report for 1929.* The work on meat deals with the influence of quality and pre-freezing treatment upon the appearance or 'bloom' of the meat after thawing, with proper conditions for transport, with the changes occurring in rigor, and with the bacteriology of frozen carcasses. The investigations on fruit include researches on wastage in store, on the chemical changes during ripening and senescence, and on variations in resistance to fungal invasion. Work has been carried out on pig products, fish, the causation of corrosion in tins, and on engineering problems of refrigeration.

The extension of the Low Temperature Research Station at Cambridge has been completed; the Ditton Laboratory at East Malling, Kent, for research on the storage of fruit is nearly ready for occupation, and the temporary buildings of the Torry (fish) Research Station at Aberdeen are in use. Special stress is laid in the Report on co-operation with industry; a combined research with the trade and members of the New Zealand Department of Scientific and Industrial Research and the Australian Commonwealth Research Council is in progress; an exhibit of frozen carcasses of mutton was held at Smithfield, and a small laboratory is maintained at Covent Garden, acting as a liaison with the trade.

As illustrative of the scope of the scientific work of the Board, certain of the researches on meat, fruit, and pig products may be referred to in more detail.

Moran and Smith report that the unpopularity of imported frozen beef is probably chiefly due to its initial poor quality, since the palatability of prime frozen beef compares very favourably with that of prime home-killed Scotch. Another factor of importance is the pre-freezing treatment, since it is during this interval that the changes associated with rigor mortis occur: in this process the consistency of the muscle substance changes, and it appears that the rate of hardening is controlled by the course of the chemical reactions which lead to the post-mortem production of heat. The formation of lactic acid is not directly associated with the hardening. The importance of the rate of freezing, the temperature reached, and the subsequent rate

* Department of Scientific and Industrial Research. Report of the Food Investigation Board for the Year 1929. Pp. 146. (London: H.M. Stationery Office, 1930.) 2s. 6d. net.

of thawing in reducing the amount of 'drip' is now well known (see also Cook, Love, Vickery, and Young, *Austral. Jour. Exp. Biol. and Med. Sci.*, vol. 3, pp. 15 and 81; 1926). Vickery has investigated the effects of freezing muscle before and after the onset of rigor, and the freezing of pure sols and emulsions; Moran has examined the rate of freezing in gelatin gels when supercooled. In the latter case, there is a critical concentration at which the rate changes from that approximating the rate in pure water to a rate only one-hundredth as great. The next stage in the treatment to which the meat is subjected is its transport to the consumer; and the temperature of transport is governed by the necessity of ensuring the absence of mould and bacterial growth, the slowing down of changes in the fat leading to rancidity, and a certain degree of rigidity of the carcass, when others are stacked upon it. Suitable conditions raise questions of biological engineering which are also dealt with in the Report.

The appearance or 'bloom' of the meat plays an important part in its value; it depends on the state of the hæmoglobin of the muscle, of the superficial fat, and of the connective tissue. The change in colour on storage is due to the conversion of the pigment to methæmoglobin and to superficial drying of the surface. Brooks has examined the former in some detail (*Biochem. Jour.*, vol. 23, p. 1391; 1929); the conversion depends on the presence of oxygen and therefore occurs only in the superficial regions into which it can penetrate: the rate of conversion, however, is maximal at a pressure of oxygen considerably less than that occurring in air. It is also increased by freezing and thawing. Lea has investigated the chemical changes in the fat during storage; under ordinary conditions they are too slight to account for any loss of bloom observed. He has also examined the accelerating influence of light upon the development of rancidity, and worked out a new test for this change. The fat is heated with glacial acetic acid, chloroform, and potassium iodide in the absence of air, and finally titrated with thiosulphate solution.

Haines has investigated the bacterial contamination of carcasses in cold store and found it to be practically negligible, although the presence of a flora capable of slow growth at low temperatures on wood and straw was detected.

Callow has examined the curing and freezing and storage of cured bacon. For scientific control it is necessary to estimate the chloride content of the meat; for this purpose the minced bacon is thoroughly extracted with boiling water, the extract treated with silver nitrate and nitric acid and boiled, the silver chloride filtered off, and the excess of nitrate estimated by Volhard's method (*Biochem. Jour.*, vol. 23, p. 648; 1929). He has also adapted the Hanes modification of the Hagedorn Jensen method for estimating glucose (*ibid.*, p. 99) to the estimation of sucrose (*ibid.*, vol. 24, p. 57; 1930). In curing, the meat takes up both salt and water, the maximum of water absorbed occurring at a concentration of 4·5 per cent sodium chloride in the meat. Mild cured bacon frozen at −25° C. can be stored successfully at −10° C. for three months.

Brief reference may now be made to some of the investigations carried out on fruit and vegetables. Barker points out that wastage depends on the intervention of a series of factors operating at various stages in the life-history from the orchard to the consumer. Moreover, different fruits, even different varieties of the same fruit, may require different optimum temperatures for storage; it is therefore very important that the temperature control of the store, for example a ship's hold, should be exact. Kidd, Onslow, and West have continued their investigations of the relationship between duration of life, respiratory activity, and nitrogen content in apples; the relation between respiratory activity and nitrogen content is direct but roughly inverse with the duration of life. At the same time, the rate of loss of sugar and acid and the potash content play a part in prolonging or shortening the life of the fruit. Haynes and Archbold have continued their work on the metabolism of apples; improvements in the methods of estimating glucose and fructose have been made; thus the iodometric oxidation is carried out at 1° C., and the rate of oxidation of fructose as well as the time necessary for the complete oxidation of glucose have been carefully worked out.

Storage life can be divided into three periods: in the first the products of hydrolysis of starch are the materials chiefly respired; in the second the products of inversion of sucrose are utilised, but the reducing sugar increases at the same time: in the third, products of sucrose inversion as well as reducing sugar are combusted. The phases of development of the growing apple have also been studied: in the first there is a rapid increase in size accompanied by a slow increase in sugars and the laying down of cell-wall material; the second is a period of maximum synthetic activity associated with starch-formation and nitrogen-intake; in the third, synthetic activity declines, the rate of formation of total solids decreases, starch synthesis and acid synthesis cease, and sucrose accumulates.

Bracewell, Hoyle, and Zilva have investigated the antiscorbutic potency of different varieties of apples by means of tests on guinea-pigs, and have found that 'Bramley's seedling' is markedly more active than all the others, that soil, age of tree, and season have no influence on the activity, and that three months' storage results in only slight loss, cold storage being better than gas storage at a higher temperature (*Biochem. Jour.*, vol. 24, p. 82; 1930).

West has noticed that storage life is favourably influenced by a few weeks of warm, dry weather preceding the date of gathering. Tomkins has found that acetaldehyde vapour is absorbed by healthy fruit and apparently utilised: at the same time, the vapour is fatal to fungal spores on its surface and to fungal mycelium. This fact may find an obvious practical application. Horne has found that the susceptibility of apples to fungal invasion is closely correlated with their nitrogen content, and that the resistance changes with the age of the fruit.

Obituary.

DR. E. B. KNOBEL.

EDWARD BALL KNOBEL, who died on July 25 last, was born in London on Oct. 21, 1841. He was educated at Stockwell Grammar School and at the Royal School of Mines, but did not take a university degree; he was given an honorary D.Sc. at Oxford in 1927. He was engaged in business as a manufacturer throughout the greater part of his life, and his work for astronomy could be done only in his leisure hours.

Dr. Knobel's published work began in 1873 with papers containing observations, illustrated by sketches, of Jupiter and Mars. He also invented a photometer and produced two papers on observations made with it. But his work as an observer was terminated by his removal from Burton to London in 1875. There he found an opportunity for studying astronomical bibliography, which determined the main drift of his studies for the rest of his life. In 1876 he presented to the Royal Astronomical Society a "Chronology of Star Catalogues", dealing with all the star catalogues the existence of which he could trace. With unimportant exceptions he had examined them all with his own eyes. To this collection he added a separate collection of catalogues of proper motions and a table of the names and places of stars contained in Aboul Hhassan's first catalogue. He also included notes on errors in texts of Ulugh Beg and Cusa, which, like those in the text of Aboul Hhassan, he attributed to misreadings of Arabic numerals. In the same year Dr. Knobel published a reference catalogue of books and papers on double stars, variable stars, red stars, nebulæ and clusters, proper motions, stellar parallax, and star spectra.

During the next forty years Dr. Knobel produced numerous papers on points connected with star catalogues, including those of Ulugh Beg, Al Sufi, and Al Achsasi, in which he displayed a growing confidence in his reading of Arabic and Persian manuscripts. He also published in 1905 a collection of the observations contained in the Japanese chronicle, the Nihongi, and edited a Chinese planisphere in 1909 with a valuable commentary. But Dr. Knobel's largest works were his editions of the star catalogues of Ptolemy and Ulugh Beg, published in 1915 and 1917 respectively. In each case the work had been begun by the German-American astronomer Peters, who died in 1890 and whose papers passed into Dr. Knobel's hands. In neither case did Dr. Knobel give a critical Greek or Persian text, but the work is based on a careful collation of the manuscripts in different languages for star places and magnitudes, and each star was identified, so far as identification is possible.

Probably Dr. Knobel contributed even more to astronomy by his long and devoted service to the Royal Astronomical Society than by his publications. Except for the one year, 1922–23, he was a member of its council uninterruptedly from 1876 to his death. He was twice president, 1892–93 and 1900–1; for fifteen years he was treasurer and for ten years secretary, and he will be remembered with gratitude by all British astronomers.

J. K. F.

WE regret to announce the following deaths:

Prof. A. Gullstrand, formerly professor of physiological and physical optics at the University of Uppsala, and Nobel prizeman for medicine in 1911, aged sixty-eight years.

M. Joseph Achilles Le Bel, For.Mem.R.S., formerly president of the French Chemical Society, on Aug. 8, aged eighty-three years.

Prof. J. F. Pompeckj, professor of geology and palæontology in the University of Berlin, on July 8, aged sixty-three years.

Dr. Harvey Washington Wiley, from 1883 to 1912 chief chemist of the U.S. Department of Agriculture, on June 30, aged eighty-five years.

News and Views.

THE lives and labours of those eminent English botanists and naturalist travellers, Sir William and Sir Joseph Hooker, and their connexion with Halesworth, Suffolk, will receive recognition on Aug. 17, through the unveiling of a tablet memorial in St. Mary's Church, Halesworth, a dedicatory duty to be performed by Sir David Prain, a former director of the Royal Botanic Gardens, Kew. The requisite funds for the erection of the tablet were provided by a number of representative scientific institutions, supplemented by contributions from a small band of botanists and others who were contemporary with Sir Joseph Hooker.

SIR WILLIAM HOOKER, born at Norwich on July 6, 1785, was educated there at the grammar school. He died on Aug. 12, 1865, in his eighty-first year, and was buried in the churchyard of St. Anne's, Kew. Here it should be mentioned that his residence at Halesworth comprised the period 1809–1820. The story of the elder Hooker's varied career was mirrored with filial care by his son Joseph in the *Annals of Botany*. Early devoted to ornithology, entomology, and botany, he found a friend in Sir Joseph Banks. On the latter's advice he explored Iceland (1809). From 1820 to 1840 he was Regius professor of botany in the University of Glasgow. A vigorous pedestrian, Hooker, when taking weekly rest at Helensburgh, habitually on Sunday walked to Glasgow—twenty-two miles—to be in time for his eight o'clock Monday morning class. In 1841 he became director of the Botanic Gardens, Kew, remaining in office twenty years. Sir Joseph Hooker, born at Halesworth, on June 30, 1817, graduated at the University of Glasgow in the medical faculty. His scientific achievements, whether as naturalist, traveller in unexplored regions of the world, or as a master of botanical nomenclature, scarcely need recapitulation. His friendships were with men such

as Darwin, Lyell, Huxley, Wallace. He followed his father in the directorship at Kew, became president of the Royal Society, and was an original member of the Order of Merit. Hooker the younger died in 1911, aged ninety-four years.

ON Aug. 19 occurs the centenary of the birth of the distinguished German chemist Julius Lothar Meyer, whose career recalls some of the most famous men of science and some of the greatest scientific achievements of the nineteenth century. The son of a doctor, Lothar Meyer became the pupil of Virchow, Ludwig, Bunsen, Kirchhoff, and Neumann; he succeeded Fittig and was the joint recipient with Mendeléeff of the Davy medal of the Royal Society. Born at Varel in Oldenburg, a province which had already given Mitscherlich to chemistry, Meyer became a student of medicine at Zurich and Würzburg, and it was on the advice of Ludwig that he devoted himself to chemistry. At Heidelberg, where he attended the lectures of Bunsen and Kirchhoff, he counted among his fellow-students Baeyer, Roscoe, Beilstein, and Quincke. Appointed a *Privatdozent* at Breslau in 1859, he undertook the direction of the laboratory of the Physiological Institute and in 1864 published his "Modernen Theorien der Chemie", by which his name was first brought into prominence. Two years were spent as a teacher at the school of forestry at Neustadt, Eberswalde, and in 1868 he was called to Carlsruhe, where for a time his work was interrupted by his care for the wounded of 1870. His final appointment came in 1876, when he was chosen successor to Fittig in the chair of chemistry at Tübingen, and this position he held until his death at Rastede on April 11, 1895. His brother, Oskar Emil Meyer (1834–1909), was the well-known physicist.

THE life of Lothar Meyer was written by his pupil Seubert, while the memorial lecture to the Chemical Society was delivered by Prof. P. P. Bedson in 1896. With great intellectual gifts, Lothar Meyer possessed characteristics which gained for him the esteem and appreciation of his contemporaries. Though his scientific publications embraced a great variety of subjects, his name is best known for the share he had with Newlands in England and Mendeléeff in Russia in the periodic classification of the elements. Speaking of the Periodic Law, Thorpe said: "The first chemist of note to grasp the significance of Mendeléeff's generalisation was Lothar Meyer, who, dealing at the outset with one of the characteristic properties of the elements—viz. their specific or atomic volumes . . . greatly developed the principle of periodicity, representing it graphically in a most striking and suggestive manner, leading up to a classification almost identical with that of Mendeléeff". It was for this work that Lothar Meyer was awarded the Davy medal in 1882. Lecturing three years later, Meyer himself spoke of Mendeléeff's contribution as forming "the coping stone of the building which in the course of years has been erected on the foundation of Döbereiner's Triads, as a work which did not, like Pallas Athene, spring ready armed from the head of a Jove, but has been gradually completed by the slow, painstaking, and often apparently vain endeavours of a whole series of workers".

THE Royal Institution has issued further particulars of the arrangements being made to celebrate the historic discovery by Faraday of electro-magnetic induction, recorded in his diary on Aug. 29, 1831. Jointly with the Institution of Electrical Engineers, the Royal Institution has drawn up a provisional programme for Sept. 21–23 next year. The first day will be devoted to the reception of delegates at the Royal Institution and a Faraday commemorative meeting in the Queen's Hall, the proceedings of which will probably be broadcast by the B.B.C. Following this will come the joint conference of the Institution of Electrical Engineers and allied associations, conversaziones at both the Royal Institution and the Institution of Electrical Engineers, and the opening of a Faraday Exhibition in the Albert Hall. The latter, which will be open to the public for about ten days, will include reproductions and illustrations of Faraday's work, and special exhibits showing the full development of electrical and chemical science and industry which have their origin in his researches. It is further proposed to publish Faraday's diary of his experimental work in full and to issue a souvenir volume. The delegates will also be entertained by the Royal Society. The Faraday celebrations will precede immediately the opening of the centenary meeting of the British Association, which is to take place on the evening of Sept. 23 in the Central Hall, Westminster.

THE purpose of the work of the Rothamsted Experimental Station is, as the director, Sir John Russell, states at the beginning of his recently issued annual report, "to discover the principles underlying the facts of agriculture and to put the knowledge thus gained into a form in which it can be used by teachers, experts and farmers for the upraising of country life and the improvement of the standard of farming". But the results of the work of the large and expert staff engaged in the Rothamsted laboratories and on the experimental plots contain much of scientific interest, especially as regards certain specific problems. The artificial inoculation of lucerne, a process developed in the Bacteriological Department for supplying the nitrogen-fixing organisms, is increasingly used at home and overseas. Study of the relationship of the nodule-organisms to the plant has shown that they do not normally enter the plant until the true leaves begin to form, when the root extrudes a substance, not yet determined, which facilitates their entry. Work on barley indicates the possibility of visualising the relationship between growth and the quality of the grain; and a simple method has been elaborated for estimating the amount of extract obtainable from a given sample of malt, an important aid to the maltster. Experiments with sugar beet emphasise the need of new varieties better suited to English conditions. The roots refuse to respond to schemes of manuring which are successful with mangolds and potatoes, though there is an increase in the leaves.

OF great value to overseas farmers is a process which has been devised at Rothamsted for converting straw and other cellulose-containing plant residues, such as the 'trash' from sugar-cane plantations, into useful manure. The chemistry of the process is being worked out. The organisms mainly concerned in the decomposition of the straw are fungi, including several Aspergilli and Actinomycetes. An important discovery by the Microbiological Department is that of a group of nitrifying organisms producing nitrites from various ammonium salts, but differing from the previously known forms, *Nitrosomonas* and *Nitrosococcus*, in that they thrive in the presence of organic matter. They are found to be commonly distributed in the soil. In the Plant Pathological Department physiological and genetical work on fungi has been continued. The subject is a complex one. Strains apparently identical in structure and cultural reactions differ markedly in pathogenic properties, and conversely, strains different in structure and cultural reactions have similar pathogenic properties. Two or more strains are frequently intermingled in one host-plant. Progress has also been made in the study of virus diseases, those elusive phenomena which can only be studied in their effects on the infected plant. The activities of the staff are indicated by the inclusion of abstracts of the scientific papers, twenty-seven in number, published during the year. The report may be obtained from the Secretary of the Rothamsted Experimental Station, Harpenden, price 2*s*. 6*d*.

ARCHÆOLOGICAL excavations on the projected line of the new by-pass at Colchester have now been in progress under Mr. C. L. Hawkes of the British Museum since the middle of June. It will be remembered that this work was undertaken by the Colchester Excavation Committee to avert the loss of valuable archæological material by the making of the new road. The area of operations has since been extended owing to the purchase of adjacent land by the Essex County Council for playing-fields, which has been placed at the disposal of the Committee until the end of August. The results obtained to date, of which a report appeared in the *Times* of Aug. 4, are of very great interest, especially in their bearing upon the relations of Britain and the Continent in the century before the Roman conquest. They fully support what was previously known of the importance of Colchester as a centre of British culture and prosperity. It would appear that this low-lying site was an overflow area from the British town, at first not too thickly populated. Then after several decades, at about 10 B.C., it was more thickly settled under Cunobelinus. The site was abandoned at about 47–50 B.C. when the Romans built their Colonia near by on virgin ground. In the ten-acre field, nearer the Roman site and farther from the centre of the Celtic town, the remains are more scattered. The abundant pottery and metal work point to a period of great prosperity in British Colchester for a period of fifty to sixty years before the Roman conquest. With much native pottery and many native brooches is a large proportion of imported ware and ornaments, pointing to a considerable volume of pre-Roman trade with Italy, southern and northern Gaul, Belgium, and the Rhine area. The numerous coins include early Roman types, issues of Cunobelinus himself, the Iceni and native issues from Gaul. The conduct of the excavations has now been taken on by Mr. J. N. L. Myres of Oxford.

THE menacing condition of the South Italian volcanoes is fully discussed by Prof. H. Reck in *Matériaux pour l'Étude des Calamités*, No. 1, 1930. The changes in Vesuvius since 1906 as studied by Malladra and Friedlaender are passed in review and the lava-flows of 1926, 1927, 1928, and 1929 are described with maps. The later eruptions are distinguished not only by the higher temperatures of effusion but also by the greater abundance of the gases and the increase in hydrochloric acid. Vesuvius is clearly heading towards another catastrophic outburst like that of 1906. The villages on the southern flank (Terzigno, etc.) are most likely to be in danger from future flows, if, as is anticipated, the southern walls of the cone are fractured by the accumulating stresses. Areas likely to be overwhelmed with ashes and vapours cannot be predicted, as they will depend on the atmospheric conditions at the time. Etna is also in a slow crescendo of activity as indicated by the 1928 eruption and its unusually high temperature. Although there can be no direct connexion between the volcanic hearths of Etna and Vesuvius, there have nevertheless been numerous coincidences between their eruptions which suggest that both may be affected by common tectonic disturbances.

IT is known that for every kilogram of grain consumed in the world to-day there is approximately a kilowatt hour of energy expended. The grain is a necessity, but some think that the world would be happier without this great expenditure of machine labour. The rapidly advancing mechanisation of labour is, it is thought, tending to make work more monotonous and hence leads to a craving after amusement and to the lowering of the mentality of the race. In an address to the World Power Conference at Berlin, an abstract of which is given in the *Electrical Review* for Aug. 8, Dr. A. F. Enstrom combats this view. In his opinion, the operation of machines instead of dulling the faculties sharpens them. A skilled operator is instantly on the alert when the noise made by his machine alters by a minute amount. His powers of observation are always being exercised. The younger generation seems to grasp with ease how to operate motor-cars and how to look after machinery. Schoolboys even have done valuable research work with home-made radio sets. The great advantage of the mechanisation of labour is that it makes possible an eight hours' day. The labourer has to expend much less muscular effort during the course of it. There is no evidence that this lowers his mentality and he has opportunities for improving his knowledge which his predecessors never had.

THE scientific instrument industry of Great Britain has deservedly a high reputation for the quality of its

products, a reputation which the Institute of Physics has done much to foster through the publication of the *Journal of Scientific Instruments*. Appreciation of its services to the industry is shown by the recent decision of the British Optical Instrument Manufacturers Association to offer an annual prize, to be known as the B.O.I.M.A. Prize, for the best paper appearing in the *Journal of Scientific Instruments*. The prize, which is of the value of ten guineas, is offered for a period of five years, the award being entirely in the hands of the Board of the Institute of Physics. The Board has accordingly decided that in awarding the prize, all papers appearing in the *Journal* during the year will be considered and due weight will be given to (1) originality, (2) scientific value, (3) practical utility to instrument makers or users, (4) presentation. The first award will be made in 1931 in respect of a paper published in the *Journal* during 1930. It is also announced that through the generosity of a member of the Board, it has become possible for the Institute to offer a prize of £5 for the best "Laboratory and Workshop Note" which appears during the year. The donor has guaranteed this prize for a period of five years. These notes serve a useful purpose in acting as the medium through which the devices, special methods, etc., evolved in one laboratory or workshop are passed on to other workers. The first award of this prize will also be made in 1931, in respect of a note published in the *Journal* during 1930.

A SERIOUS obstacle in the development of radio telegraphy and telephony was the difficulty in developing high voltage direct current for supplying the amplifiers of transmission plants, as the necessary voltages vary from 9000 to 30,000. An early solution was to adapt motor generator sets coupled in series so as to obtain the requisite voltage. The large demand led to considerable improvements in their design so that sets can now be built which will give pressures of 15,000 volts. The main drawback to this solution was the comparatively long time required to start the reserve set if anything went wrong. The next solution was thermionic rectifiers, which can be put into use at a moment's notice. The disadvantage in this case was the great expense of upkeep, as their life is limited to about 5000 hours. The most recent and perhaps the best solution is to use mercury arc rectifiers. We learn from the *Brown Boveri Review* for July that this solution has been adopted by Marconi's Wireless Telegraph Co., Ltd., in the firm's research laboratories at Chelmsford. The rectifier and rectifier transformer were designed for an output of 400 kilowatts at direct current pressures of 9000, 10,000, and 12,000 volts. The plant was installed a year ago and has given entire satisfaction. It has a high efficiency, can be started at a moment's notice, and withstands short circuits. Water cooling of the rectifier is not necessary as radiation and convection suffice to lead away the thermal losses. The new large broadcasting station which is to be opened shortly at Warsaw will be equipped with two Brown Boveri rectifiers which will give an output of 500 kilowatts at from 10,000 to 15,000 volts.

THE meetings of the International Electrotechnical Commission which were held on June 27–July 9 in all three Scandinavian countries were very successful, twenty-two countries being represented. The opening meeting was held in Copenhagen, the advisory committees carried out their work in Stockholm, and the plenary meeting took place at Oslo. The committee on nomenclature after considerable discussion adopted the following names for the magnetic C.G.S. units. The unit of magnetic flux was called the 'maxwell' and the unit of flux density the 'gauss'. The unit of magnetic field intensity was called the 'oersted' and of magnetomotive force the 'gilbert'. It will be some time, however, before these names are adopted in text-books in Great Britain. Following the Italian suggestion, a unit 10^8 times as large as the maxwell has been adopted for practical engineering use. It is proposed to call it the 'pro-maxwell'. The committee on the rating of machinery had a long discussion as to the maximum permissible temperature at which machinery and apparatus should work. Engineers consider that a few degrees centigrade in the permissible temperature is of great practical importance. A unanimous decision was ultimately reached. The symbols committee reached agreement on the symbols to be used in telephony, telegraphy, radio communication, and electric traction. It was thought a pity that the standardised symbols are not more widely used by the Press and in industry. The aluminium committee had difficulty in reconciling European and American practice, but some progress was made in this direction. A proposal to standardise 132 kilovolts, which is the British grid pressure, was rejected.

A RECENT *Daily Science News Bulletin* issued by Science Service, Washington, D.C., gives some details about the progress of the plans which are being developed by Dr. Robert Goddard, professor of physics at Clark University, Worcester, Mass., for exploring the atmosphere at high levels by means of rockets. A liquid propellant has been perfected which is said to have many advantages over gunpowder or similar explosives. The rocket continually becomes lighter as it ascends owing to the burning of the propellant. The rockets will be sent upwards from a steel tower at Camp Devens, near Worcester, Mass. As yet only small rockets have been fired, which have ascended to levels of but a few hundred feet. A grant has recently been made by Mr. Daniel Guggenheim for the extension of the experiments, and an influential advisory committee has been appointed in connexion therewith. When it becomes possible to send rockets up to altitudes measured in tens of kilometres instead of hundreds of feet, carefully devised instruments will be added to the rocket with a parachute to bring them safely to earth when the charge is exhausted.

TRIALS of new and improved combine harvester-thresher machines have been arranged by the Ministry of Agriculture at Wellingore, Kesteven, Lincs., through the courtesy of Mr. Geoffrey Nevile. Farmers desirous of seeing these machines in operation may either send the cost of a telegram, or telephone to the

Estate Office, Wellingore (14X5 Fulbeck, Grantham), and they will be informed so far as possible of the exact day or days when harvesting is being carried out. At first it was thought that such machines would be unsuitable in England, since the grain in this country is much more moist at harvest time than is the case in Canada or the United States, where the combine method is widely used. However, judging from last year's experience in the trials carried out by the Oxford Institute of Agricultural Engineering, it seems probable that, although in some seasons a drying plant might be necessary, threshing may be safely carried out after the grain has stood for a day or two in summer heat. This view is supported by experience abroad, and the combined machine is becoming increasingly used in countries with cooler and wetter climates. Given favourable conditions for hire or purchase, the farmer would gain considerably by their general introduction into Great Britain, as not only would the total cost of harvesting and threshing be reduced, but also loss from vermin or mould in the stack be avoided.

THE Balkans correspondent of the *Times* gives an interesting account—in the issue of Aug. 4—of the health reform measures carried out in Yugoslavia during the last ten years. The person to whom most credit is due is Dr. Andriya Shtampar, who was appointed head of the Department of Hygiene in the Ministry of Health in 1919. The sanitary condition of the country was then deplorable, not only as the result of the War but also as the consequence of centuries of neglect, as was shown by the fact that 80-90 per cent of the population were infected with malaria and syphilis, while enteric fever, typhus, and smallpox were extremely rife. Dr. Shtampar's first step was to provide himself with competent assistants, who had to be trained abroad, and then to persuade the government to supply the necessary funds for his reforms. Since 1923, when he was first really able to start work, he has organised three main categories of institutions: (1) central institutes for each of the nine provinces, (2) 80 district health institutes, and (3) about 500 village stations. The central institutes comprise departments of bacteriology and parasitology, social medicine, and sanitary engineering. The district institutes contain departments for mother and child welfare, dispensaries for venereal diseases and tuberculosis, bacteriological laboratories and bath houses. The village institutes consist of a dispensary in charge of a nursing sister, a small health exhibition, and a shower bath. A school of hygiene is attached to the Zagreb Central Institute for the training not only of doctors and nurses but also for instructing the more intelligent peasants in the general principles of hygiene. Dr. Shtampar's work has received liberal aid from the Rockefeller Foundation as well as the strong support of King Alexander. The reduction in epidemic disease as the result of these measures has been most gratifying. During the last two years, there have not been more than a hundred cases of typhus in the country, there has been no smallpox for more than a year, and the incidence of malaria has fallen from 80 to 10 per cent, while there is a good prospect of a healthy generation growing up in formerly disease-ridden areas.

THE following appointments have been made by the Secretary of State for the Colonies: Dr. G. Bryce to be deputy assistant director of agriculture, Nigeria; Mr. B. G. Montserin to be agricultural officer, Trinidad.

THE Royal Microscopical Society, after residing in Hanover Square, London, for some forty years, has removed to new apartments in B.M.A. House, Tavistock Square, Bloomsbury, W.C.1, in which its library and slide collections will be more adequately housed, and where, in addition to the Society's lecture halls, meeting rooms, and offices, a portion of its unique collection of historical instruments will be on permanent exhibition.

AT the Brisbane meeting of the Australasian Association for the Advancement of Science which took place on May 28–June 4, it was decided by the General Council to change the name of the Association to "The Australian and New Zealand Association for the Advancement of Science". The Mueller Memorial Medal for 1930 was awarded to Sir Douglas Mawson for his contributions to Australian geology, associated with which are his achievements in geography and exploration. The first Liversidge Research Lecture under the bequest from the late Prof. A. Liversidge was delivered by Prof. N. T. M. Wilsmore, of the University of Western Australia, the title of the lecture being "Chemical Research and the State".

DR. HAROLD THOMPSON, senior naturalist on the staff of the Fishery Board of Scotland, has sailed for Newfoundland, where he will undertake on behalf of the Government of Newfoundland and of the Empire Marketing Board a survey of the fisheries. This is the first step in the formulation of a scheme having as its object the development on scientific lines of Newfoundland fisheries. The work in contemplation will embrace a systematic and statistical review of the fishery resources with the view of developing methods for the preservation, handling, and marketing of the fish (including brine freezing), and for the utilisation and marketing of surplus fish and fish by-products. The cost of the preliminary survey is being shared equally between the Government of Newfoundland and the Empire Marketing Board.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A full-time teacher for mining courses under the West Riding Education Committee—The Education Officer, County Hall, Wakefield (Aug. 18). A cotton entomologist and an assistant pathologist in the Department of Agriculture and Stock, Brisbane—The Official Secretary, Queensland Government Offices, 409 Strand, W.C.2 (Aug. 20). A lecturer in civil engineering in the University of Birmingham—The Secretary, The University, Birmingham (Aug. 21). A temporary research assistant in civil engineering in the University of Birmingham—The Secretary, The University,

Birmingham (Aug. 21). Principal teachers of, respectively, mechanical engineering, mathematics and physics, and chemistry; also a qualified mechanic for taking care of the plant, and a laboratory steward to take charge of the laboratories at the Technical College, Coatbridge—The Director of Education, Lanarkshire House, 191 Ingram Street, Glasgow, C.1 (Aug. 22). A junior assistant in the department of the War Department Chemist—The War Department Chemist, B.47, Royal Arsenal, Woolwich, S.E.18 (Aug. 23). A lecturer and demonstrator in the pharmacy department of the Birmingham Central Technical College—The Principal, Central Technical College, Suffolk Street, Birmingham (Aug. 25). A cacao soil research chemist at the Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 14 Trinity Square, E.C.3 (Aug. 30). A lecturer in mechanical engineering at the Norwich Technical College—The Principal, Technical College, Norwich (Sept. 3). An assistant in the Cancer Research Laboratories of the University of Manchester—The Registrar, The University, Manchester (Sept. 7). A demonstrator in chemical pathology in the University of Manchester—The Registrar, The University, Manchester (Sept. 13). A medical man or woman research worker in mental deficiency under the Medical Research Council, the governing body of the Darwin Trust, and the Committee of the Royal Eastern Counties Institution for the Mentally Defective at Colchester—The Medical Superintendent, Royal Institution, Colchester (Oct. 3). A chemical laboratory assistant in the experimental department of the Fine Cotton Spinners' and Doublers' Association, Ltd.—Prof. F. P. Slater, Rock Bank, Bollington, Macclesfield. Assistant masters for engineering subjects and for chemistry at the Smethwick Junior Technical School—The Director of Education, Education Offices, High Street, Smethwick. An assistant under the Directorate of Ballistic Research, Research Department, Woolwich, with several years' research experience in physics—The Chief Superintendent, Research Department, Woolwich, S.E.18. A temporary research assistant in a Government Department, with, preferably, a knowledge of rubber technique and mechanical methods—The Chief Superintendent, Chemical Warfare Research Department, 14 Grosvenor Gardens, S.W.1. A temporary laboratory assistant in a Government Department, with, if possible, a general knowledge of chemistry and physics and of rubber manufacture—The Commandant, Experimental Station, Porton, near Salisbury.

Our Astronomical Column.

New Variable Stars in the Constellation Norma.—Arrangements have been made for the interchange of observers between the observatories of Johannesburg and Leyden. Mr. H. van Gent has taken a number of plates with the Franklin-Adams telescope at Johannesburg which were measured at Leyden by W. E. Kruytbosch (*Bull. Astr. Instit. Netherlands*, vol. 5, No. 194). The blink-microscope revealed 25 variables upon them, and afforded sufficient material for plotting the light-curves, which are given in the *Bulletin* together with diagrams of the fields. The second star on the list is an eclipsing variable of the W. Urs. Maj. type. Prof. Hertzsprung suggests, from the long stationary minimum, that either the companion is a white dwarf or that the system contains a third star from which most of the light comes during minimum. There are also some Cepheid variables: *p* on the list has a period of 2·4 days and a large light-range.

Images of Pluto on Yerkes Observatory Plates.—*Astr. Nach.* 5719 contains particulars of the measures of the image of Pluto detected by Dr. F. E. Ross on plates exposed on Jan. 29, 1921 (two plates) and Jan. 6, 1927. The positions are for the equinox of 1930·0. The magnitude of Pluto was estimated as 15 on each date.

U.T.	R.A.	N. Decl.	Aperture. (Inches.)	Focal Length. (Inches.)	Exposure. (Minutes.)
1921.					
Jan. 29·0806	$6^h\ 31^m\ 22{\cdot}04^s$	$19°\ 43'\ 13{\cdot}7''$	10	50	192
	22·01	13·6			
	22·28	14·1	6	30	192
1927.					
Jan. 6·2500	7 4 3·17	21 13 3·1	3	21	120

The estimated probable error is 1″ for the focal lengths 30 in. and 21 in., somewhat less for the 50-in. focus. The first 50-in. measure and the 30-in. measure were made by Prof. van Biesbroeck using three comparison stars in the Paris Astrographic Catalogue. The other measures were made by Dr. F. E. Ross using the star Berlin *A* 2257 for the 1921 plate, and three Paris Astrographic stars for the 1927 plate. No proper motions were applied. The 1927 position is in good accord with the revised measures of the image obtained at Uccle on Jan. 27, 1927. It is stated that the 1921 images were identified with the aid of the ephemeris of Prof. T. Banachiewicz (*U. A. I. Circular* 284), and the 1927 one with the aid of a manuscript ephemeris by Messrs. Bower and Whipple.

Astr. Nach. 5719 also contains a useful collection of the observations of Pluto obtained in March and April last: they are compared by Dr. C. H. Smiley with an ephemeris which he deduced from the following heliocentric positions and velocities derived by Prof. Banachiewicz for the date March 31·0 and the equinox of 1930·0.

		Daily Change.
$x=$	$-13{\cdot}29363$	$-0{\cdot}0020443$
$y=$	$+35{\cdot}84738$	$-0{\cdot}0017048$
$z=$	$+15{\cdot}41587$	$+0{\cdot}0000824$

The Photo-electric Cell at Berlin-Babelsberg.—*Astr. Nach.* 5713 contains a study by P. Guthnick and R. Prager of early-type stars, the duplicity of which had been detected at the Victoria Observatory by spectroscopic observations by Dr. Plaskett and Dr. Pearce. In five cases light-variation was detected, indicating mutual eclipses. *H.D.* 19820 has minimum masses of 19 and 9 times that of the sun. It is of type *O*8, but its colour is yellow: the other stars on the list are also yellow. *H.D.* 25638 has a period of 1·1487 days from the Berlin observations. Plaskett found a velocity range of 293 km./sec., but did not determine the period. *H.D.* 25639 is also an eclipsing binary, only 18″ from the preceding star, with which it forms the pair Σ485, but the light range is only 0·05 mag. The period is not yet determined.

Research Items.

Smoking in Papua.—Dr. A. C. Haddon, who is investigating tobacco smoking in Papua, communicates to *Man* for August an account by Capt. G. F. N. Zimmer of a method of smoking tobacco hitherto unrecorded, which is in use among bush natives on and to the west of the Fly River in an area including Shortland River and Lake Murray. The tobacco or a native cigarette is inserted in one end of a tube or cigarette holder—a narrow bamboo tube about nine inches long — and this end they place against a glowing log or fire-brand. When the tobacco is thoroughly alight, the end containing the tobacco is placed in the mouth and the other end inserted in the wider end of an arm guard or bracer which has been removed from the smoker's left arm, this end of the bracer being closed by the right hand, the tube going between the smoker's fingers. The narrower end is closed by the smoker's left hand. The bracer, *posiki*, is made of nine slats of wood, about 25 cm. long and tapering from 31 mm. to 25 mm. in width. The slats of wood are firmly lashed on both sides with rattan so as to make a very rigid object. The smoke is blown into the bracer through the tube. The tube is then removed and the smoke inhaled by slightly moving the left hand. This method of smoking is usually employed while hunting or when away from the village. It is in no way a freak, but has been observed on many occasions as a regular method in these circumstances.

Agricultural Rites in Northern Nigeria.—Mr. C. K. Meek describes in *Africa* for July (vol. 3, No. 3) the ceremonies observed by the Bachama of the Benue River in the cult of Nzeanzo, who is enshrined at Fare, a Bala village some seven miles east of Numan. Nzeanzo is believed to be the youngest of five sons of a woman named Venin, who herself receives divine honours in an annual mourning ceremony observed in April. The cult of Nzeanzo is the most honoured among the Bachama. It is in the hands of a kindred at Fare of which the head is called Kisami. He is assisted by a relative, who acts as spokesman on all occasions, and a man of another kindred who prepares the beer and food used in the rites. A woman known as Mbamto acts as intermediary between the god and the people. She is a perpetual virgin who has come from the district of Kona and is regarded as the bride of the god. She is not psychic and if she develops hysterical symptoms she is sent away. The principal festival of the cult is held at the end of April and lasts three days. The king, though not a priest, is regarded as president of all cults and is held responsible for the due performance of all rites. If he should fail in providing gifts at stated periods, any misfortune to the people would be regarded as due to his default. The Fare festival is primarily concerned with the opening of the agricultural year and precedes the sowing of the crops. It is even more important than the thanksgiving rites. Formerly one of the king's children was sacrificed annually during the fertility rites of 'Pilla' carried out at Lamurde. In comparatively recent times, the human victim was replaced by a cow. At Nafaran no one may sow his crops until the priest of the Nafaran cult has carried out certain rites and distributed the seed which he has had under his keeping, and is therefore believed to have magical qualities. Among the Jukun, Kona, and Mbum the seed-corn is distributed by the chief, and is the produce of the royal farm. This was apparently the custom of the old Bachama kings, and to this day the produce of the royal farm is considered the property of the community.

Fauna of South Africa.—Report No. 7, for the year ending June 1929, of the Fisheries and Marine Biological Survey, Union of South Africa, contains, besides general matter relating to the fisheries, several papers in the "Special Reports", amongst which are two of special value. These are Dr. C. H. O'Donoghue's "Opisthobranchiate Mollusca" and Mr. M. Burton's "Description of South African Sponges" collected by the South African Marine Biological Survey. The first is a long, systematic paper on various forms chiefly belonging to the tectibranchs (sixteen species) together with a few nudibranchs (five species). Amongst these are five new species of tectibranchs and three new species of nudibranchs. The examination of such a collection is a thankless task, for all the specimens are preserved and have lost their original beauty, which in life may be marked, and the absence of coloration in most cases makes diagnosis difficult. Nevertheless, Dr. O'Donoghue has managed to extract a large amount of information out of the collection, the radulæ, shells (when present), and jaws serving as valuable distinctive features, and these are fully figured in eight plates. *Euselenops lunicipes* (Cuvier) is specially carefully and minutely described, with details of its anatomy, although only one specimen was present. This is identical with *Neda luniceps* described by Adams and Reeve in 1848. Mr. Burton in his critical survey of the desma-forming sponges abandons for ever the family Lithistidæ, the heterogeneous collection of forms which have hitherto been placed together on account of the similarity of their skeletons being provisionally referred to several different families. Six species are recorded from South Africa, including one which is new. *Lithochela conica*, a new genus and species belonging to the Myxillæ, is also described.

Atlantic Foraminifera. — Dr. Joseph Augustine Cushman continues his valuable series of memoirs on "The Foraminifera of the Atlantic Ocean", the present part (7) consisting of the Nonionidæ, Camerinidæ, Peneroplidæ and Alveolinellidæ (Smithsonian Institution, United States National Museum, *Bulletin* 104, 1930). As in former parts, the species are specially described which have occurred in the waters adjacent to the shores of the United States, including the whole of the Gulf of Mexico and the Caribbean Sea, which is the area chiefly worked by the vessels of the United States engaged in dredging. These families are all represented by simpler and usually smaller forms than in the Indo-Pacific, where some of the species reach to a very large size. The Nonionidæ are most abundant in rather shallow water; three genera occur and numerous species. *Elphidium* is common, also *Nonion* and *Nonionella* in rather deeper water. The Camerinidæ are almost wanting in the Atlantic, the Peneroplidæ and Alveolinellidæ being represented by simpler and more primitive species than in the Pacific. The new species *Peneroplis bradyi* is common in the West Indian region, occurring at numerous stations off the Tortugas and the Florida Keys, at Bermuda and Jamaica, probably replacing *Paneroplis planatus*, which apparently does not occur in the western Atlantic.

Osteology of Pediculate Fishes.—Mr. Albert Eide Parr, in his paper entitled "On the Osteology and Classification of the Pediculate Fishes of the genera Aceratias, Rhynchoceratias, Haplophryne, Laevoceratias, Allector, and Lipactis" (Occasional Papers of the Bingham Oceanographic Collection, Peabody Museum of Natural History, Yale University, No. 3,

1930), discusses the homology of the rostral bone of Rhynchoceratias and describes the new species *Rhynchoceratias longipinnis* with special reference to its osteology. He finds that the median, unpaired rostral bone of this genus which forms the anterior part of the upper border of the mouth, supplying through its denticles or spines the only functional dentition of the upper jaw apparatus, has nothing to do with the mesethmoidal bones of these fishes, but is homologous with the illicium of other ceratoids, representing an extreme phylogenetic modification of the most anterior dorsal fin ray (spine) of ordinary teleosts. The relationships of the other genera are discussed and the family Aceratiidæ divided into two sub-families, the Eurostrinæ, to which *Aceratias* and *Rhynchoceratias* belong, having the dorsal denticles inserted on a well developed rostral bone, and the Cryptorestrinæ, including *Haplophryne* and *Lævoceratias*, in which the rostral bone is reduced or absent.

Iron in Humus.—Some explanation of the beneficial influence of humus substances on the growth of green plants in water culture has been brought forward by C. Olsen (*Comptes-Rendus du Laboratoire Carlsberg*, vol. 18, 1930). The solution of the much-debated question as to whether or not humus is beneficial to plants grown under these conditions centres round the form in which the iron is presented, and the reaction of the nutrient solution. *Lemna* plants grow equally well in a culture solution of pH 6·0, whether humus was added or not, provided the iron was given in the form of ferric citrate, but if ferric chloride was substituted for the citrate the addition of humus greatly improved growth. The explanation given is that under neutral or alkaline conditions iron is not available to the plant unless it is in the form of an organic compound such as citrate. The watery extracts of peat contain such complex organic iron combinations, and are therefore useful to the plant for the available iron they provide. In support of this theory attention is directed to the fact that chlorosis is often noticeable in Nature among plants growing on calcareous soil poor in humus, whereas on soils of similar pH but containing humus, the symptoms of iron deficiency do not appear.

Geophysics in the United States.—The United States National Research Council has issued (June 1930) the *Transactions* of the American Geophysical Union for both the tenth and eleventh annual meetings (April 1929 and May 1930) in one volume (pp. 314, no price stated). The reports of previous annual meetings (up to that for 1928) appeared about a year after the date of the meetings. The remarkable promptitude of publication of the report of this year's meeting is due largely to the adoption of photo-lithographic reproduction from typescript for the whole of the material. The result is not quite so readable or pleasing to the eye as printed matter, but the advantage of early publication seems to outweigh this drawback, in view of the necessarily mainly ephemeral interest of the reports and papers, which deal largely with matter published more fully elsewhere. The Union meets as a whole and in seven sections; the reports and papers numbered 54 (at the 1930 meeting) and cover a wide range of important and interesting topics in geophysics.

Magnetic Data from Mauritius.—Miscellaneous Publications of the Royal Alfred Observatory, No. 8, is devoted to a summary and discussion by the director, Mr. R. A. Watson, of "The Disturbed and Quiet Day Variations of Magnetic Force at Mauritius, 1916–26". The inclusion of quiet and disturbed day inequalities in the monthly bulletin of the observatory is not possible, and their collection and discussion for an 11-year period in this publication is therefore of special value and interest. The outstanding feature of the results is the manner in which disturbance is almost entirely confined to H (horizontal force). In D (declination) and V (vertical force) the inequalities are almost unmodified by disturbance, whereas in H both the type and the range of the inequality are entirely different on the two sets of days, quiet and disturbed. Even on international quiet days H usually shows some small disturbance, and though world-wide disturbances are in general considerably less intense at Mauritius than in latitudes 50° or more, small disturbances (in H) are more frequent at Mauritius, so much so that it is usually difficult to select one day in any given month as a typically undisturbed day.

Turner Valley Oilfield, Alberta.—Western Canadian oil possibilities have certainly derived stimulus from the developments on the Turner Valley oilfield, Alberta, of which Mr. E. H. Cunningham Craig gave some account to the Institution of Petroleum Technologists recently. In fact, it is not too much to state that if American interests in the oil potentialities of the Rocky Mountain region have flagged somewhat from the non-discovery of a second Salt Creek Oilfield, they have certainly been reanimated by the results of the last six years' work at Turner Valley, where geological conditions are closely allied to those in the relevant Rocky Mountain States. The Turner Valley anticline was first proved a producing structure by the drilling of the Royalite No. 4 oil-well some five years ago, and since then other producing wells have been completed. Significant interest attaches to this well, as it produced filtered oil and wet gas in considerable quantity; its present output is more than 500 barrels of light gasoline per day. It may be recalled that Alberta has in the past been specially noted for its enormous reserves of natural gas, chiefly of a dry character, with comparatively little oil; so that the Turner Valley developments are of more than usual importance. Some fifteen miles of the structure have been proved and other areas outside Turner Valley have been and are being prospected. The source of this oil and gas has revived the old controversy of upward or downward migrated oil. On one hand there is the possibility of derivation from Palæozoic (Devonian) horizons, and, on the other, from the Jurassic or lower Cretaceous. The author favours the latter source and inclines to the view that the parent oil rocks are of Kootenai age (base of Lower Cretaceous) with subsidiary possibilities in the overlying Dakota Sandstone. He dismisses the possibility of Palæozoic origin on the chief count of probable escape and loss of oil during the lengthy geological period intervening between the critical formations, during which considerable orogenic movement and accompanying erosion were accomplished. On the other hand, there is no doubt that the chief reservoir rock is a dolomitic limestone of pre-Jurassic age; so that, if the "stratigraphically downward migration" theory is proved, which we cannot easily admit on the basis of the facts so far presented, a most important principle, applicable to many other limestone fields in the world, is thus established.

Ionised Regions of the Upper Atmosphere.—Some fresh investigations of the upper air by wireless methods, which differ chiefly from earlier ones in the use of short waves and in the multiplication of the number of receiving stations, are described by Prof. E. V. Appleton, J. A. Ratcliffe, and A. L. Green in two papers in the July issue of the *Proceedings of the Royal Society*. These now show conclusively that

even relatively long waves (400 metres) occasionally pass through the lower ionised layer (the E region) at night when it is at a height of approximately 100 kilometres, and are then returned from the F region, which has a greater concentration of electrons, and is approximately two to three times as high. With shorter waves (100 metres) the penetration of the E layer occurs frequently, the waves being returned from it usually only in the middle of the day, when it is still at a height of approximately 100 kilometres. The equivalent height of the E layer for 400 metre waves varies very little with the angle at which they are incident upon it, and there is likewise little variation in the reflection coefficient, to explain which it is suggested that there is a zone below the E layer which causes considerable attenuation of the waves, without, however, deviating them. The receiving station at King's College, London, at which many of the interference records have been obtained, is distant only 18 kilometres from the transmitting station at Teddington.

Collisions Between α-Particles and Helium Atoms.—The solution of the problem of collision between two particles which act upon each other with forces varying as the inverse square of the distance between them is the same in quantum mechanics and in classical mechanics, unless the particles are identical. In this case an important additional term appears in the quantum theory expression for the probability of scattering, and it is possible to decide between the old and the new theory by experiment. A test of this nature, in which the number of particles projected through 45° by slow α-particles passing through helium is measured, is described by Dr. J. Chadwick in the *Proceedings of the Royal Society* for July. An annular type of scattering apparatus was used, with a strong polonium source, and a zinc sulphide detecting screen. The number of particles deviated was definitely greater than would be expected on classical theory, and for the slowest particles used, of range about 1·2 cm. in air under standard conditions, was close to the number predicted by quantum theory. A fundamental theoretical assumption which is verified by this result is that the helium nucleus has no spin or vector quantity associated with it, and that its field of force is spherical.

Measurement of Candle Power of Electric Lamps.—The measurement of the candle power of lamps is one of the most difficult problems that physicists have to solve. The probable error of the routine tests of comparing the candle powers of incandescent lamps by visual methods in the factory are of the order of at least 2 per cent high or low. This is due not to carelessness but to the real difficulty which every observer has in judging when two surfaces have the same brightness or when two shadows have the same intensity. This is apart altogether from the difficulties arising in determining the mean intensity of the light emitted and from those arising from differences of colour. In a paper communicated to the May number of the *Journal of the Institution of Electrical Engineers*, Mr. Winch, of the G. E. C. Research Laboratories at Wembley, describes a photo-electric photometer for the commercial measurement of incandescent electric lamps. It seems to us that this instrument will go an appreciable way in meeting the commercial demand for higher accuracy combined with very rapid measurement. Whilst the eye must, of necessity, be the ultimate source of reference, there seems reason to believe that in the near future commercial photometry will, in general, be carried out photo-electrically. As an experiment, lamps were measured in the ordinary photometric way and the work done was equivalent to having five observers working for four days, without taking into account the time taken in making calculations. The same series of tests when carried out photo-electrically by one observer took four hours. The method is capable of being developed so as to obtain higher accuracy and also so as to obtain spherical integration with one reading.

Turbo-Vapour-Compressors for Refrigeration.—Among the Selected Engineering Papers chosen to be published in pamphlet form by the Institution of Civil Engineers is one by Dr. H. Mawson on "Turbo-Vapour-Compressors and their Application to Refrigeration". While reciprocatory compressors have been developed for refrigeration, turbo-compressors have not received serious consideration, and in the paper an attempt is made to consider the thermodynamic and practical possibilities of this type. Fundamental equations which are applicable to liquids, gases, and vapours are applied to the flow of fluids through a centrifugal compressor; the choice of a fluid for centrifugal compression between definite temperature limits is considered and the performance of a sulphur dioxide turbo-compressor for a given temperature range is examined by the aid of the p/I chart. Outlines of the design of a sulphur dioxide centrifugal compressor of definite duty for the same temperature range are given, together with a general arrangement of the compressor, and, finally, centrifugal and reciprocating compressors are contrasted, and the possible application of the former to central-station distribution of fluids under pressure for refrigeration is also considered.

Metal Carbonyls.—The *Journal of the Society of Chemical Industry* for June 13, 20, and 27 contains a most interesting article by Dr. Robert Mond on the metal carbonyls. The early experimental work which led to the discovery of the first known member of the group, nickel carbonyl, in 1890 by Ludwig Mond and C. Langer, and the subsequent investigations (in which Dr. Robert Mond played an active part) leading to the discovery of the other metal carbonyls, are described. The properties of the carbonyls and their actual and possible technical uses are next considered, and a full bibliography of the literature is given. The Mond Nickel process, which is a very important technical application of the properties of nickel carbonyl, is dealt with at some length. These three papers constitute an important and authoritative addition to chemical literature.

Sorption of Gases by Charcoal.—The June number of the *Journal of the American Chemical Society* contains a paper by McBain and Britton on the sorption of gases and vapours by charcoal under great pressure (up to 60 atm.) The experiments were completed in 1927 at the University of Bristol. The gases used were nitrogen, nitrous oxide, and ethylene, and the temperatures used were above and below the critical temperatures. It is claimed that the results enable a decision to be reached between rival views as to the nature of sorption by charcoal, that the Langmuir conception that only such molecules are sorbed as are in direct contact with the molecules holding them is correct, and that the Saussure-Polanyi conception of a compressed film is not supported by the experiments. In this connexion, however, it should be mentioned that the same issue of the journal contains a paper on the adsorption of water and benzene vapours on manganese dioxide, by Foote and Dixon, in which it is stated that Polanyi's theory is in agreement with the data, so that the question cannot be regarded as settled.

Geology in Great Britain.

THE welcome innovation introduced last year of issuing the "Summary of Progress" of the Geological Survey in two parts is continued, one part being devoted to an account of the routine work of the year, while the other serves as a medium for the publication of a series of papers on subjects of special interest. Students are thus enabled to purchase at a reduced price the second part of the "Summary" without having to pay for the section dealing with administrative matters. Part I.[1] contains the annual report of the Geological Survey Board and of the Director. Seventy-five maps were published during 1928, together with fourteen memoirs, most of which have already been noticed in our columns (NATURE, Aug. 10, 1929). The reports of the district geologists contain many records of interest. Fieldwork was largely concentrated on the revision of the coalfields, but in Shropshire the Longmynd has been invaded afresh and a provisional classification of some of its puzzling formations is offered, while in the Lake District the relations of the Skiddaw slates, the Borrowdale volcanic series and the Carrock Fell complex are being actively attacked. The new survey of the Orkneys has yielded a fine suite of fossil fishes and plants from the Old Red Sandstone. On the petrological side, it is announced that the Tertiary igneous rocks of Ardnamurchan exemplify in a most striking way the phenomena of ring-dyke intrusion and present many important facts bearing on magmatic differentiation. Hybridisation is thought to be responsible for the reproduction of the tonalitic and monzonitic types of the central complex. Publication of full details is promised in the near future. An interesting account is given of the successful experiences of the geophysical party.

The work of the geophysical party is described at greater length in Part 2.[2] The first two papers are by W. F. P. M'Lintock and J. Phemister, and deal respectively with gravitational surveys over the buried channel of the Kelvin at Dumtry, near Glasgow, and over the Pentland fault near Portobello. The results clearly demonstrate that the method may be usefully employed to supplement boring evidence. and that in practice it is both cheaper and quicker than drilling. Sir John Flett contributes a masterly investigation of a lamprophyre dyke on the west side of Loch Lomond. The dyke is of unusual significance because of the variety of its inclusions. In so far as these provide an indication of the nature of the underlying rocks, they suggest that the sequence of formations from the Highland border northwards is a descending one; as this is not the sequence usually adopted, the suggestion may have very far-reaching consequences. T. H. Whitehead describes a presumably Arenig rhyolite occurring near Pontesford Hill in Shropshire between Ordovician and Longmyndian rocks. The remaining papers are devoted to the Coal Measures or their fossils. W. B. Wright describes the zonal succession around Manchester; R. Crookall gives an invaluable and well-illustrated summary of the stratigraphy and flora of the Bristol and Somerset coalfield; Emily Dix and J. Pringle describe various forms of *Xiphosura* from the South Wales coalfield; and T. Eastwood discusses the *nips* and *rock-riders* (interruptions in the continuity of coal-seams) of the West Cumberland field.

The district described in the Oswestry memoir[3] is represented on Sheet 137, which covers parts of Shropshire, Denbigh, and Montgomery. Ordovician formations come to the surface in the west and pass under successively later deposits, Silurian, Carboniferous (including Coal Measures), and Triassic, the latter outcropping in the east. Glacial drifts overspread the eastern half of the area. The controlling structural feature is the great anticlinal uplift of the Berwyn Hills, which enters the north-western quarter from the west. In the south-west this gives place to a synclinal depression. The tectonic features are ably discussed in relation to the larger area of which the district forms a part. There are also chapters dealing with the Palæozoic igneous rocks (albitised derivatives from an andesite magma) and with the mineral products and water supplies.

The memoir describing Sheets 320 and 321[4] will serve as a valuable guide to the geology of a popular coastal district, since it deals with Hastings, St. Leonard's, and Bexhill, and the ancient towns of Rye and Winchelsea. The solid geology is restricted to the Purbeck and Wealden, but topics of unusual interest, ranging from palæontology to sedimentary petrology, are by no means limited. The account of the superficial deposits is notable for the inclusion of a valuable description of Dungeness, a great dumping ground of beach-shingle, drifted alongshore from the chalk cliffs and flint deposits west of Eastbourne, and deposited where the interplay of tidal currents produces an area of relatively slack water.

The next memoir[5] to be noticed (Aldershot and Guildford, Sheet 285) describes an area of south-eastern England which is a favourite residential district of great geological interest and topographic charm. The Surrey Hills, composed of the Lower Greensand beds, present some of the most beautiful scenery in England. To the north of these, across the middle of the area, run the North Downs. The geology thus embraces a representative series from the Lower Cretaceous upwards. Attention is given to the evidences of early man with special reference to their distribution in the river terraces.

The country around Sudbury (the "Eatanswill" of Pickwick and his friends) is described by Prof. Boswell[6] in a memoir explanatory of Sheet 206. The geological setting is of great simplicity. Chalk underlies the whole area, but on account of the thickness of the Tertiary cover and the glacial deposits, it crops out only on the lower flanks and in the bottoms of the larger valleys. The glacial deposits are, however, far from simple. Here are found some of the finest sections of drift in Great Britain; they have been intensively studied in recent years by Gregory, Marr, Boswell, Slater, and others. This memoir is further notable for its clear account of the history of the local river systems.

Mr. E. J. Lovegrove has carried out attrition tests on some 460 samples of road-stones and his results are summarised in a recent memoir,[7] together with supplementary results on water absorption, hardness, toughness, and cementing value. Notes on the petrographical characters and their bearing on the behaviour of the specimens are added. Samples of all the stones referred to are conserved in the Museum of Practical Geology, together with a complete set of microscopic sections. The memoir is made easily available for use by the inclusion of an index to localities and a glossary of rock names and definitions. There are four excellent plates of photomicrographs with descriptions facing each plate, an arrangement worthy of special commendation.

Dr. Alex. Scott has written a report[8] in which for the first time the ball clays of the south-west of England—one of the most important raw materials of the pottery industry—are systematically dealt with. The term 'ball-clay' is applied to plastic clays which when fired in an oxidising atmosphere to the tempera-

ture of certain pottery ovens (c. 1150°–1200° C.) have a white or nearly white colour. The name refers only to the original method whereby the clay was obtained in Dorset and Devonshire, and not to any particular property. The memoir gives a complete account of the geological relations, mineral and chemical characters, and physical properties. There are numerous analyses and results of tests and a glossary of terms uxed by the clay miners.

Continuing the county series of memoirs in which the sources of underground waters are described in detail, the Derbyshire memoir[9] has been issued. It gives an admirable short account of the geology of the county, illustrated with a clear map and sections. Details are given of the local sources of supply from springs and wells, with many particulars of the strata recorded from wells and borings. A number of analyses of Derbyshire waters are supplied, and reference is made to the medicinal waters of Buxton and Matlock Bath.

Descendants of the *Bounty* Mutineers.

IN 1923, Dr. Harry L. Shapiro visited Norfolk Island for the purpose of making a series of observations on the Pitcairn Islanders, the descendants of the English sailors who survived from the mutiny of the *Bounty* in 1790 and the Tahitian women with whom they settled on Pitcairn. The Islanders removed to Norfolk Island in 1856, but some of them afterwards returned to Pitcairn. These latter Dr. Shapiro was prevented from visiting by stress of weather. The results of his observations on Norfolk Island, together with a summary of previously recorded observations of the settlement, have been published in Vol. 11, No. 1, of the *Memoirs of the Bernice P. Bishop Museum* of Honolulu.

The special interest of the anthropometric measurements depends upon the fact that they represent hybrids of two well-distinguished stocks with a long history of inbreeding. In stature the male hybrids are distinctly taller than either parent stock. The women, however, reach but do not exceed the mean for Tahitian and English. Both male and female have inherited the longer head-length of the English; in head-breadth both have inherited a head mid-way between English and Tahitian, the latter being the greater by 6·7 mm. in the male. In face breadth both sexes again show an intermediate position, the male being slightly more than the English average. In face height the males are not significantly different from the Tahitians; the females are intermediate. The hybrid males have inherited a narrow forehead which resembles the Tahitian. Other features in which the Islanders show an intermediate position are nose height (males), nose width, fronto-parietal index, and zygomatico-frontal index. The cephalic index is much nearer the English than the Tahitian, which is prominently brachycephalic, and the nasal index, though distinctly greater than the English index, approximates more nearly to it than to the Tahitian.

In eye colour, the pigmented eye of the Society Islander is dominant over the unpigmented eye, but the males have a greater percentage of blue eyes than the females. The epicanthic fold is rare among the hybrids. The unexposed skin colour of the hybrids is intermediate to the medium dark-skinned Tahitians and the relatively fair-skinned English. The exposed skin colour among the hybrids is as dark as the exposed skin of the Society Islanders. The dark hair of the Tahitian is dominant over the light hair of the English, and curved hair over straight hair. The males are also more hairy than the Tahitians. The variability of the Islanders is less than in either parent stock.

Recent Work on Vitamin D.

III.

OCCURRENCE.

ALTHOUGH cod-liver oil is the richest natural source of vitamin D, it is clear that most animals must obtain their supply from other food or by the exposure of their body surface to the sun's rays. E. M. Hume, N. S. Lucas, and H. H. Smith (*Biochem. J.*, vol. 21, p. 362; 1927) have shown that irradiated 'cholesterol' can cure rickets in the rat or rabbit when lightly rubbed into a small area of depilated skin almost as efficiently as direct irradiation of a similar small depilated area. These results afford experimental proof that exposure of the skin to a suitable source of light will result in the production of vitamin D in the exposed area, whence it will be transferred to the body tissues to exert its function.

J. L. Leigh-Clare (*ibid.*, vol. 21, p. 368; 1927) has examined the diatom *Nitzschia closterium* for vitamin D and has found it to be absent even when the organism was grown in sunlight. Up to 0·4 gm. was given as a daily dose to rats maintained on the rachitogenic diet. It appears, therefore, that the cod must obtain its vitamin D from plankton or smaller fish, since it is unlikely to be sufficiently exposed to sunshine itself (unless, of course, it possesses the power of synthesising it in the absence of the sun's rays). The absence of vitamin D from this organism may be compared with the poverty of green land plants in it. M. H. Roscoe (*ibid.*, vol. 21, p. 211; 1927) has found small amounts in spinach: its effect was more obvious in rabbits than rats, since relatively larger amounts could be consumed by the former animal. S. G. Willimott and F. Wokes point out, however, that administration of spinach involves at the same time an increase in the consumption of calcium and phosphorus: they therefore examined an ether-acetone extract of the dried leaves (*ibid.* p. 887). Twenty-five mgm. of the extract, equivalent to 6 gm. fresh spinach, were sufficient to prevent xerophthalmia

and produce nearly normal growth, from its content of vitamin A, in rats on a high fat diet: only slight signs of rickets were observed, but the fæcal pH became alkaline. On a low fat diet 100 mgm. extract daily failed to shift an alkaline fæcal pH to the acid side of neutrality, although cod-liver oil quickly brought about such a reduction. They conclude, therefore, that at a level supplying a fair amount of vitamin A, vitamin D could not be demonstrated.

It appears probable that green foodstuffs contain little vitamin D, but the amount can be increased by exposure to ultra-violet light. For the production of milk containing more than minimal quantities of the vitamin, it is best to add cod-liver oil to the cow's diet, although summer green stuffs and exposure of the animal to sunlight also raise the vitamin D content of the milk to some extent.

It is of some interest that vitamin D has also been found to be present in ergot of rye, although it might possibly have been inferred since ergosterol is an important constituent (E. Mellanby, E. Surie, and D. C. Harrison, *Biochem. J.*, vol. 23, p. 710; 1929). The authors, however, found that mushrooms, which also contain ergosterol, contain no vitamin D and that exposure of ergot to sunlight does not increase the vitamin content, although irradiation with a mercury vapour lamp does so to a slight extent. The experiments were carried out on puppies maintained on a diet deficient in vitamins A and D. The calcifying factor had the properties of vitamin D in that it was soluble in alcohol and ether and withstood saponification.

D-HYPERVITAMINOSIS.

With the preparation of vitamin D synthetically from a pure precursor, attention was soon directed to the question as to what effects, if any, the administration of large doses of the vitamin might have upon the tissues of the body. Some previous work had shown that large doses of cod-liver oil or its concentrate (that is, the unsaponifiable fraction) might have deleterious effects upon rats, but it was not possible to attribute such to the presence of a vitamin, since other substances occur in both the oil and its concentrate. In irradiated ergosterol, on the other hand, there are only present compounds formed from it, with probably some unchanged ergosterol. If, therefore, any toxic effects seen bear a relation to the known effects upon the body of vitamin D and, further, if their intensity is proportional to the amount of vitamin present, it is reasonable to attribute these effects to the vitamin itself: unless, however, a very close parallelism between toxicity and potency is observed, there always remains the possibility that another substance may play some part in producing or even mitigating any deleterious effects observed.

It is impossible here to do more than refer to a few of the papers published on this subject: some of the earliest work was carried out by Pfannensteil and Kreitmair and Moll: in Great Britain two groups of workers have devoted some attention to it (L. J. Harris and T. Moore, *Biochem. J.*, vol. 22, p. 1461; 1928: vol. 23, pp. 261 and 1115; 1929: Harris and C. P. Stewart, *ibid.*, vol. 23, p. 206: W. E. Dixon and J. C. Hoyle, *Brit. Med. Jour.*, vol. 2, p. 832; 1928: Hoyle and H. Buckland, *Biochem. J.*, vol. 23, p. 558; 1929: Hoyle, *Lancet*, vol. 1, p. 734; 1929: and *J. Pharm. Exp. Therap.*, vol. 38, p. 271; 1930).

When rats are given a synthetic diet containing all known nutritive factors, to which are added daily 10 mgm. or more of irradiated ergosterol, the animals show loss of appetite, with failure to grow or loss of weight, diarrhœa, and skin lesions: death ensues in a few weeks. The amount which must be given daily to produce these effects varies: Harris and Moore found 0·1 per cent in the diet of ergosterol irradiated in alcohol lethal, whilst 0·025 per cent of similar material or of oil-irradiated ergosterol prevented growth. Dixon and Hoyle found that 0·2 per cent in the diet of ergosterol irradiated in oily (cocoa-butter) solution, giving an average daily consumption of 17 mgm., prevented growth in half-grown rats, whilst 11 mgm. daily gave little retardation. (The daily consumption in Harris and Moore's experiments was about 10 mgm. with 0·1 per cent in the diet.) Smaller doses of irradiated ergosterol, for example, 0·001 per cent in the diet, or 0·1 per cent ergosterol, heated ergosterol or over-irradiated ergosterol in which the potency had been almost entirely destroyed, had no deleterious effects on growth. In later experiments, Hoyle found that about 26 mgm. daily of oil-irradiated ergosterol caused some loss of weight but was not lethal in young adult rats, whereas 20 mgm. of ergosterol irradiated in alcohol caused death in a short time. He therefore considers that oil-irradiated is less toxic than alcohol-irradiated ergosterol, whilst Harris and Moore consider that the two products are equally toxic: it is possible that the discrepancy may be due to differences in vitamin D potency of the materials used, or to differences in the constituents of the synthetic diets.

In addition to the deterioration in the general condition of the animals noticed above, slowing of the heart has been observed and an increase in the inorganic phosphate and calcium of the blood. In addition, irradiated ergosterol produces a marked diuresis but without any increase in the total phosphate or chloride output. Post-mortem, the pathological changes vary in general with the toxicity as disclosed by the effect on growth, except that time is required for their development, so that early death may be accompanied by few lesions, whilst a prolonged maintenance on a low dose may produce as marked changes as a shorter existence upon a high one. The general condition is one of emaciation, with atrophy of the spleen and thymus: in addition, calcareous deposits are found in the kidneys, blood-vessels, heart muscle and the walls of the gastrointestinal tract. The calcification of the walls of the aorta is often particularly striking; the deposits appear to be laid down at first in close connexion with the elastic fibres; on macroscopic examination the tube is brittle and inelastic. Similar sclerosis occurs in the vessels of the heart and kidneys. These changes are not found in animals on non-toxic doses of irradiated ergosterol, or given large doses of ergosterol, or heated or over-irradiated ergosterol. Dixon and Hoyle found that the only lesions in their rats given 11 or 17 mgm. oil-irradiated ergosterol daily were calculi in the urinary tract, frequently accompanied by hydronephrosis and also some degree of fatty change in the kidneys.

The nature of the diet has a marked influence upon the toxicity of irradiated ergosterol: on a natural diet of bread and milk, 20 mgm. of alcohol-irradiated material daily had little effect upon the growth of young rats although producing cessation of increase in weight in the case of young adults. Pathological lesions were correspondingly absent or slight. It is possible that this is due to a lessened intake of calcium and phosphorus on the bread and milk diet (Harris, *Lancet*, vol. 1, p. 237; 1930), although Hoyle considers that this result should be compared with the lower toxicity of oil-irradiated material found by him and that it is in favour of the toxic factor and vitamin D being different substances. It might be suggested that early death is due to a different substance from vitamin D: and that the sclerosis observed in relatively long time experiments is produced by the vitamin and leads later to a fatal result.

It may be pointed out that the toxic amounts of irradiated ergosterol in these experiments contain from 10,000 to 100,000 times what may be called the physiological dose of vitamin D. In healthy adult men, Havard and Hoyle found that 8 mgm. daily for three weeks in winter failed to raise the blood inorganic phosphate or serum calcium and had no toxic effects (*Biochem. J.*, vol. 22, p. 713; 1928). Hess and Lewis, however, found that 2·5-5 mgm. daily in rachitic infants, whilst curing the disease, might lead to an excessive rise in the blood phosphorus and calcium.

In conclusion, brief reference may be made to a paper by Harris and Moore in which it is shown that the requirement of the rat for vitamin B is increased *pro rata* with increase in the intake of vitamins A and D in the form of a cod-liver oil concentrate. The amount of vitamin D consumed was below the level which had previously been found to be toxic (when given in the form of irradiated ergosterol), whilst the amount of vitamin A taken was up to 25,000 times the minimum dose. It is considered that the 'vitamin balance' is probably between vitamins A and B, although the possible action of other unidentified substances cannot be excluded when both sources of the vitamins contain other materials.

University and Educational Intelligence.

APPLICATIONS are invited for the following research scholarships at the Huddersfield Technical College: The Joseph Blamire's Research Scholarship for research in colour chemistry (value £100 a year, with remission of fees), and the British Dyes Research Scholarship for research in colour chemistry (value £75 a year, with remission of fees). Forms of application can be had from the Secretary of the College.

ROBERT BLAIR fellowships have been awarded to Mr. Cyril H. Bowden and to Mr. Philip Carpenter. These fellowships, which carry a grant of £450, are the most valuable scholarship awards in the gift of the London County Council. Mr. Bowden has been engaged upon research work in the physical chemistry department of the Imperial College of Science, and proposes to study chemical engineering at the Massachusetts Institute of Technology, U.S.A. Mr. Carpenter, who is an associate of the Royal School of Mines, proposes to visit mines in the United States to study the principles and practice of the flotation process for separating minerals from their ores, with a view to the value of its application on the large copper field now being opened up in Northern Rhodesia.

FROM the University of Cambridge we have received summaries of dissertations approved for the Ph.D., M.Sc., and M.Litt. degrees during 1928–29, as follows: in science 44, in the humanities 12, total 56. By departments the dissertations are thus distributed: departments of the faculties of biology 22 (biochemistry 6, geology 6, botany 4, zoology 3, physiology 3), chemistry 9, agriculture 6, mathematics 4, physics 3, English 4, classics 3, modern and mediæval languages 2, economics and political science 1, history 1, moral science 1. The preponderance of science, especially biological science, is remarkable. So likewise is the fact that of the 56 candidates 34 were drawn from other universities in every quarter of the globe, namely, from London (4), Wales (4), Manchester (2), Sheffield, St. Andrews, Glasgow, Aberdeen, Berlin (moral science) Lausanne (mathematics), Budapest (biochemistry), Pisa (chemistry), four universities in the United States of America (English, modern and mediæval languages, chemistry, and physiology), two Canadian universities (history and agriculture), four Australian universities (botany, geology, biochemistry, English, chemistry), New Zealand (botany, geology, physics), South Africa (chemistry), and Bombay (zoology).

IF the number of doctorates conferred in the sciences be proportionate to the advance of the frontiers of knowledge, there has been a notable acceleration in the progress of science in the United States during the past ten years. 1928–29 is the tenth year for which particulars of such doctorates have been compiled by the Research Information Service of the American National Research Council, and its recently published bulletin on the subject shows a steady increase from 330 in 1919–20 to 1025 in 1928–29. The University of Chicago alone created 99 new doctors last year, Wisconsin 66, Johns Hopkins 62, Columbia 61, Cornell 60, Minnesota 53, California 50, Ohio State 48, Yale 47, Harvard 40, fifty-one other universities 439. Of greater interest than the list of conferring universities is the list of subjects in which the degrees were conferred. This discloses the portentous fact that, excluding chemistry, which is in a class by itself, accounting for nearly a third of the total number, more doctorates (112) were conferred in what has only barely established its claim to recognition as a science, namely, psychology, than in any of the other sciences. The universities chiefly responsible are: Iowa (15), Ohio (13), Chicago (10), Columbia (9), Cornell (9), Minnesota (8), Wisconsin (6), and Yale (6). The titles of the theses indicate in many instances the schools of psychological doctrine in which the writers are interested, and a very large proportion of them are attempts to solve practical educational problems. Next to psychology come, in the order given, physics, zoology, botany, mathematics, geology, physiology, engineering, pathology, agriculture, and bacteriology.

THE report of the work of the Petroleum Department of the Sir John Cass Technical Institute for the session 1929–30 is now available, and shows that satisfactory progress has been made in all sections. The close of the session to which the report relates marks the completion of the third triennium of the activities of the department. The courses provided embrace lectures on general technology of petroleum, bulk transport and distribution of petroleum products, introduction to the chemical and physical properties of petroleum; properties, applications, and examination of petroleum, and its applications to engineering. There is also a preliminary course in elementary physics, chemistry, and mathematics, as a basis of introduction to the subject of oil technology for those who have little or no knowledge of first principles. The total number of class entries for the session was 160 as compared with 145 last session, student hours showing an increase from 2153 to 2876. The report, as in previous years, gives no indication of the syllabus of the lectures offered, so that it is not possible to form an idea of the precise ground traversed in the several courses. While a report is naturally not intended to constitute in itself a prospectus, at the same time these annual reports of the Petroleum Department of the Institute have always seemed to us rather bald statements, and the inclusion of a little more internal detail is desirable; for example, the names of all the lecturers who have contributed to the work, results of any particular research which may have been inspired by the Institute, some mention of the companies whose representatives have attended courses, any particular departures from or modifications in routine designed to keep the curriculum up-to-date, plans for the future, and so on: all this is of direct import not only to the School itself, but also to those for whom it so adequately caters.

Historic Natural Events.

Aug. 17, 1876. Electrical Phenomena near Weymouth.—At Ringstead Bay, near Weymouth, Dorset, during a sultry afternoon, on ground above the cliffs, a number of globes of light were seen of the size of billiard balls, extending from a few inches above the surface to a height of 7-8 ft. They slowly rose and fell vertically, sometimes within a few inches of the observers but always eluding the grasp. The number of these objects varied from twenty to 'thousands'. No sound accompanied the display, but at 10 P.M. there was a thunderstorm.

Aug. 17, 1929. Shyok Glacier Floods.—Near its source the Shyok River, a tributary of the Upper Indus, flows through a narrow valley, into which the Kumdan Glaciers protrude. At times the glaciers advance to the opposite wall, completely blocking the valley and damming the river. This occurred in 1928 and 1929, when the ice dam was 1000 yards long and more than 400 feet high. The force of the great volume of water broke through the barrier on Aug. 17, 1929, and a disastrous flood followed. At Khalsar, where the river runs through a narrow gorge, it rose rapidly to 93 ft. above the normal level, and by 8 P.M. on Aug. 18 the flood, travelling about 20 miles an hour, had raised the level by above 50 ft. at Attock, 600 miles from the dam. Owing to the system of warnings which had been arranged, the losses of life and property caused by the flood were comparatively small.

Aug. 18, 1631. Aurora.—The account of the search for the North-West Passage by Capt. Luke Foxe in His Majesty's Pinnace *Charles* contains an entry made on Aug. 18 at the mouth of the Nelson River, Hudson Bay: "This night 10 were many Pettiedancers". Mr. W. J. Healy of the Provincial Library, Winnipeg, explains that the term 'Dancers' or 'Merry Dancers' is a local name for the aurora borealis.

Aug. 18, 1923. Typhoon at Hong Kong.—The centre of a violent typhoon passed within 14 miles of Hong Kong. On Aug. 18 the calm centre had a diameter of seven miles, outside which the winds had a velocity of more than 100 miles per hour, while a gust was recorded, after correction for instrumental error, of 127 miles per hour. This was at the time the highest wind velocity ever recorded autographically.

Aug. 19, 1867. Thunderstorm over London.—After a day of intense heat one of the greatest London thunderstorms began at 9 P.M., and continued until 5 A.M. next morning. The lightning was continual, and the thunder scarcely ceased. Rain fell in torrents, accompanied by a violent wind and in some places by hail. The storm was very violent in all parts of Surrey and in some parts of Sussex and Berkshire.

Aug. 19, 1880. Typhoon.—This disturbance, known as "The Great Typhoon of 1880", originated to the east of the Liu Kiu islands on Aug. 19–22. On Aug. 24–27 it travelled north-eastward along the east coast of Japan, doing great damage.

Aug. 19, 1889. Cloudburst in Japan.—The Kii Peninsula, on the south of Nippon, was the scene of a deluge of rain unequalled in the history of Japan. On Aug. 18, a typhoon approached the south coast, and during Aug. 19 crossed the inland waters to the Sea of Japan, causing a southerly gale over the Kii Peninsula. Heavy rain was experienced on Aug. 18, and on Aug. 19 the rain was so violent and continuous that a considerable area was devastated. At Tanabe the fall was 14·5 in. on Aug. 18, and 35·5 in. on Aug. 19, the latter quantity falling in 17 hours. During a period of four hours from 2 P.M. to 6 P.M. the fall amounted to 14·25 in. and near by 9·5 in. fell in two hours. The observer reported that in the mountains of the interior the rain was even heavier. The Izugawa, a tiny stream only eleven miles long, became a devastating torrent. The lower part of Tanabe was deeply flooded, while a stream south of Tanabe rose 50 feet in two hours. Hundreds of thousands of trees were washed out to sea, forming temporary dams in the valleys which added to the flooding; 1502 lives were lost and 400,000 persons were ruined.

Aug. 19, 1924. Heavy Rain in British Isles.—During a thunderstorm in the early morning, a total of eight inches of rain fell in five hours at Brymore House, near Cannington in Somersetshire. In the twenty-four hours ending at 9 A.M. the fall amounted to 9·40 in., the second largest recorded in the British Isles. It appears that two or three thunderstorms followed one another in rapid succession. After the storm hailstones lay on the ground to a depth of three or four inches, but were not especially large.

Aug. 21, 1852. Eruption of Etna.—A violent eruption of Etna, that lasted more than nine months, began on this day. Streams of lava flowed from craters in the Val del Bove, on the south-east side of the mountain, one stream advancing towards Zaffarana and another threatening La Macchia and Giarre. The total volume of lava was estimated to cover an area 6 miles long and 2 miles wide to an average depth of 12 ft.

Aug. 23, 1923. Sandstorm at Khartoum.—During a violent sandstorm at Khartoum the wind reached a velocity of 62 miles per hour. Many large trees were blown down. During storms of this type the dust is raised to a height of about 3000 feet, and advances across the ground like a solid wall ten or twenty miles in length.

Societies and Academies.

LONDON.

Geological Society, June 25.—**J. E. Richey**: Tertiary igneous complex of Ardnamurchan. The district is chiefly noteworthy on account of its intrusive rocks, and only small outliers of the widespread Tertiary plateau basalt-lavas are preserved. The types of intrusion include volcanic vents piercing the basalt-lavas, and largely filled with acid and trachytic fragmental materials; minor intrusions, including cone-sheets, chiefly quartz-dolerite, and dykes; and plutonic masses, nearly all gabbro or dolerite, occurring mainly as ring-dykes. The above, excepting the dykes, are arranged in concentric series around three different centres, marking three foci of igneous activity which functioned successively. It is suggested that the three complexes are successively more deep-seated, due, presumably, to the growth of an overlying volcanic pile. The regular ring-patterns marked by the intrusions are of more especial interest and constitute evidence of the formation of annular or arcuate fissures that are considered here, as in Mull, to have resulted from localised stresses set up in the roof of an underlying magma-reservoir.

PARIS.

Academy of Sciences, June 23.—**Bigourdan**: The Observatory of Cagnoli in the rue de Richelieu.—**Ernest Esclangon**: The determination of an orbit, planet or comet, by three observations, taking into account the perturbations caused by other planets.—**Léon Guillet and Marcel Ballay**: The influence of reheating on the electrical resistance and resistance to shearing of the tempered aluminium-silicon alloys.—**Louis Roy**: The propagation of waves on isotropic elastic surfaces with three parameters.—**André Nessi and Léon Nisolle**: A machine for calculating by means

of a planimeter the integral of the product of two functions.—**T. Popovici**: Convex functions of one real variable.—**Georges Bouligand**: The figuration of imaginary points and the theory of functions.—**Michel Fekete**: Series of factors keeping the class of a Fourier's series.—**Luigi Fantappié**: The extension of a theorem of M. Hadamard to series of multiple powers.—**F. E. Myard**: An absolutely general mode of linkage of two axes of rotation in space.—**Nicolas G. Perrakis**: The sensitometric study of a new panchromatic plate. A study of a Guilleminot panchromatic plate, with special reference to the interpretation of photographs of the solar corona taken on similar plates.—**André Marcelin** and **Mlle. S. Boudin**: Stratifications coloured by sublimation. A description of the technique necessary to obtain crystals suitable for microscopic examination.—**René Lucas**: The mutual influence on their absorption bands of the chromophore groups of a molecule.—**J. Aharoni** and **Ch. Dhéré**: Study of the influence exerted by the exciting rays on the fluorescence spectrum of etioporphyrin. The structure of this spectrum from the infra-red to the ultra-violet.—**L. Goldstein**: The distribution of potential and charge in a diatomic molecule.—**Lespieau** and **Bourguel**: Chemical constitution and the Raman effect: ethylenic hydrocarbons. As regards the Raman effect, the double bonds of the benzene nucleus give the same effect as ordinary ethylene double bonds; both are characterised by the line 1600. The Raman spectra of six hydrocarbons of known composition have been studied and the results applied to the verification of the structure of a new double ring hydrocarbon, phenyltrimethylene.—**G. Arrivaut**: The formation of a violet copper alloy, Cu_2Sb. This has been prepared by the action of a 10 per cent solution of antimony chloride containing some free hydrochloric acid upon finely divided copper.—**Maurice François**: The rational preparation of the bromides and chlorides of mercurammonium. Crystallised dimercurammonium bromide and dimercurammonium chloride.—**M. Tiffeneau** and **Mlle. Jeanne Lévy**: The affinity capacity of the piperonyl radical, $CH_2O_2C_6H_3$.—**Urion**: The decomposition of divinylglycol by various catalysts: 1-methylal-1-cyclopentene.—**H. Colin** and **P. Ricard**: The glucides and the glucidic derivatives of the brown Algæ.—**H. Lagatu** and **L. Maume**: Observation, by leaf diagnosis, of the influence of temperature on the mode of nutrition of a plant.—**Emile Saillard**: Adsorption in the sugar industry.—**A.** and **B. Chauchard**: Sleep produced in fishes by compression of the brain.—**D. Bennati** and **E. Herzfeld**: The action of formaldehyde on neuromuscular excitability.—**P. Sédallian** and **Mme. Clavel**: The use of flocculated diphtheric toxin in the preparation of antidiphtheric serum. Other conditions being the same, and with some reserve as regards individual reactions of animals, experimental proof is given that the toxin precipitated at pH 4·7, brought into solution in a suitable volume of peptone solution, furnishes an antigen of at least equal value to that of the total toxin.—**H. Simonnet** and **G. Tanret**: The calcification of the lung in the healthy or tuberculous rabbit by larger doses of irradiated ergosterol.—**S. Bratianu** and **C. Guerriero**: The phagocytic power of the epithelial cells of the mammary gland.—**Mlle. G. Cousin**: The endoparasitic development of the ectoparasitic larva of *Mormoniella vitripennis*.

CAPE TOWN.

Royal Society of South Africa, May 21.—**P. R. v. d. R. Copeman**: Changes in the composition of oranges during ripening (Part 2). Changes in soluble solids. The percentage of soluble solids in the juice and the weight of soluble solids per fruit both increase during ripening. The changes follow the course of an autocatalytic reaction. During the final three weeks the effects of transpiration become dominant and the percentage soluble solids show an abnormal increase. Spraying with lead arsenate mixtures does not produce any significant change in the amount of soluble solids.—**B. Farrington**: The life of Vesalius by Boerhaave and Albinus. A translation of the preface by Boerhaave and Albinus to their edition of the works of Vesalius. It contains a brief history of anatomy from the earliest times until its revival in Italy in the beginning of the fourteenth century. It gives a more extended account of the work of the Italian pioneers; and then establishes the epoch-making importance of the work of Vesalius. The career of Vesalius is treated in considerable detail and with many lively biographical touches. This preface of theirs is not now readily accessible in Latin, and has not before been translated into English.—**A. Zoond** and **G. Rimer**: The mechanism of equilibration in *Xenopus Lævis*. An analysis of the function of the eyes and the labyrinthine organs in connexion with equilibrium and the response to rotation. Whereas extirpation of eyes and labyrinths abolishes completely the response to rotation on a turntable, eyed labyrinthless animals do respond to such rotation by definite muscular movement. This response is still maintained when the animal is rotated in total darkness. The same phenomenon is recorded also for *Rana*.—**A. Zoond**: Dermal photoreceptivity in *Xenopus Lævis*. *Xenopus* is negatively phototropic and response is not in any way affected by the removal of the eyes, the eyeless animals reacting to light in the same way as the eyed. Immersion in 1 per cent cocaine solution for six minutes completely abolishes the sensitivity to light of the eyeless animals, although the spinal reflexes are not impaired. These observations demonstrate the presence of photoreceptive elements in the skin of *Xenopus*.

CRACOW.

Polish Academy of Science and Letters, Mar. 3.—**W. Seislowski**: The radiation of semi-conducting cells.—**D. Doborzyński**: The dielectric constant of liquid bromine.—**K. Kostanecki**: The course of the cæcum of the great bustard, *Otis tarda*.—**F. Rogoziński** and **Mlle. M. Starzewska**: Experimental rickets. The influence of ultra-violet light on the mineral metabolism and on the composition of the bones. Experiments on the white rat prove the favourable action of irradiation on the retention of calcium and of phosphorus.—**L. Monné**: Comparative researches on the structure of the Golgi apparatus and of the vacuome in the sexual and somatic cells of some gastropods (*Helix*, *Paludina*, *Cerithium*).—**St. Ciechanowski**: (1) Study of tar cancer tumours. (2) The influence of the anatomical structure of the region exposed to tar on the appearance and development of tar tumours.—**K. Sciesiński**: The influence of the species of the rabbit on the appearance and development of tar tumours.—**St. Ciechanowski** and **K. Sciesiński**: Pregnancy and tar tumours. The influence of the intensity of the local agent on the formation and development of tar tumours in the rabbit.—**R. Weigl**: The nature and forms of the micro-organism of exanthematic typhus.—**R. Weigl**: The methods of active immunisation against exanthematic typhus.—**L. Hirszfeld** and **Mlle. W. Halber**: The serological unity of cancers.

April 7.—**T. Banachiewicz**: First orbit of the trans-Neptunian star.—**A. Wilk**: Discovery of a new comet.—**Wl. Gorczyński**: Values of the intensity of the solar radiation measured on board different vessels

on the Atlantic and Indian Oceans.—**E. Chauvenet** and **J. Dawidowicz**: Zirconyl oxyiodides.—**K. Dziewoński, Cz. Baraniecki**, and **L. Sternbach**: A new method of synthesis of colouring matters of the thio-indigo type. Syntheses in the naphthalene group.—**J. Kuhl**: Contribution to the knowledge of the Trembowla grits in the neighbourhood of Mogielnica (Eastern Little Poland).—**Mlle. C. de Kleist**: Phyto-sociological researches on the peat bogs of the region of the dunes of the right bank of the Vistula in the neighbourhood of Warsaw.—**Z. Grodiński**: The development of the blood vessels in the anterior extremities of *Amblystoma mexicanum*.—**J. Zacwilichowski**: Researches on the innervation of the wings of insects.—**L. Hirszfeld** and **Mlle. W. Halber**: Deviation of the complement by the serum of cancer patients and of pregnant women with alcoholic extract of cancers.—**Z. Zakrzewski**: Researches on the production of the principles stimulating the growth of normal tissues by sarcomatous cells in culture *in vitro*.

MELBOURNE.

Royal Society of Victoria, June 12.—**John Clark**: New Formicidæ; with notes on some little-known species. Fourteen species and one genus are described as new. The ants described by Kirby in 1896, collected by the member of the Horn Expedition to Central Australia, have been revised. Of the twelve species mentioned by Kirby, five now stand as apparently valid species.—**Alan P. Dodd**: New Hymenoptera Proctotrypoidea from Victoria. Six new species are described, belonging to the families (1) Scelionidæ and (2) Belytidæ. The genus *Xenotoma* is here recorded for the first time from Australia.—**Alan Coulson**: Notes on the Jurassic Rocks of the Barrabool Hills, near Geelong, Victoria. Fossil plants, of which a list is given, were discovered in a mudstone band intercalated with basal boulder beds. The flora indicates a Lower Jurassic age. The pebbles of the boulder beds are Ordovician spotted slate, quartzite, quartz and mica schist, Heathcotian (Up. Cambrian) epidiorite, and Lower Palæozoic granite. Two faults have affected the Jurassic beds.

SYDNEY.

Linnean Society of New South Wales, May 21.—**C. P. Alexander**: Observations on the Dipterous family Tanyderidae. A preliminary description of the immature stages of the family Tanyderidæ. The material consists of larvæ and pupæ of a North American species, *Protoplasa fitchii*, from the Gaspé Peninsula of eastern Quebec, Canada. More than half the known species of the family are from Australasia, which is the great centre of distribution of the family.—**H. L. Jensen**: The genus *Micromonospora* Orskov, a little-known group of soil micro-organisms. Morphological and biological description of nine strains of the practically unknown genus *Micromonospora*, which appears to be of common occurrence in Australian soils.—**A. Jefferis Turner**: Revision of Australian Oenochromidæ (Lepidoptera). Part 3. This completes the revision of the family. In this part twenty genera and forty-seven species are dealt with, one genus and six species being described as new. Keys are given for the determination of the species of *Oenochroma* and *Derambila*.

VIENNA.

Academy of Sciences, May 22.—**G. Machek**: The linear pentacene series (19). The constitution of the bi-derivatives of pentacene-diquinone.—**M. Kohn** and **E. Gurewitsch**: The 2, 5-dichlor-hydro-quinone-dimethyl-ether.—**M. Kohn** and **S. Fink**: Chlorination of *p*-amido-phenol. 35th. Communication on bromophenols.—**K. Przibram**: Recrystallisation and coloration of rock-salt.—**G. Ortner**: Recrystallisation of compressed rock-salt. **M. Blau** and **E. Rona**: Application of Chamie's photographic method to reactions and electrolysis of polonium.

The Royal Veterinary College.

It would indeed be a national calamity if the Royal Veterinary College, London, the premier veterinary college of the British Empire, had to close its doors. The precarious condition of the College was emphasised by the Earl of Harewood recently in the House of Lords when he asked what steps the Government is prepared to take to maintain it. Reference to Lord Harewood's speech and to the discussion which followed was made in our issue of Aug. 9, p. 212.

Less than a year ago there was issued as a White Paper the report of the Departmental Committee on the Royal Veterinary College appointed by the Minister of Agriculture and Fisheries in 1928. The report stated that "the condition of the Royal Veterinary College is a national disgrace, it needs rebuilding and re-equipping". After a very thorough investigation the Committee stated clearly that "the deplorable condition to which the College has been reduced both as regards buildings and finance has not been due to any lack of enthusiasm on the part of those few members of the Governing Body who for many years past have been sufficiently public-spirited to devote attention to the affairs of the College, or to the small staff who, despite their meagre salaries and wholly inadequate facilities, continued loyally at their work. It is nothing less than extraordinary that the College has been able, in spite of the most depressing circumstances, to turn out year by year a regular flow of qualified students." The necessities of an Institution have never, we venture to state, been more strongly emphasised by a Government departmental committee, and it should have been unnecessary for the question to have been raised again in either House of Parliament.

The response of the Government to the appeals which have been made is frankly disappointing, and one wonders if the responsible ministers have really taken the trouble to read the report or to weigh up its import. The committee recommended a grant of £280,000 for building and equipment, and a guaranteed annual income of not less than £21,000. The Government offer, as stated by the Earl de la Warr, of pound for pound up to £100,000, is totally inadequate in view of the circumstances. The governors have collected £30,000 as the result of four or five years' urgent endeavour and urgent appeal, and it is believed to be absolutely impossible substantially to increase that amount, so that the offer is practically abortive. Lord Ernle pointed out in the debate in the House of Lords

that in Berlin the *annual* sum paid for veterinary science is £280,000, and yet in London a single capital grant of that same amount is refused.

Earl de la Warr suggested that Lord Harewood and his friends should confer with the Ministry of Agriculture before coming to a decision as to the future of the College. While agreeing that the Ministry of Agriculture is the chief ministry concerned with veterinary science, we agree with the suggestion recently made by Major-General Sir John Moore that other ministries are also vitally concerned and that a conference of responsible heads of those ministries might be held to consider the necessities of the case, with the view of obtaining a proportionate grant from each of them. The Lovat Committee appointed by the Colonial Office emphasised the importance of a good supply of fully trained veterinary officers for the Colonies; the Ministry of Health requires veterinary officers for its administration, particularly in regard to milk supply and meat inspection as well as in respect of animal diseases communicable to man; the Ministry for War still requires a fully competent Army Veterinary Corps, and will continue to do so in spite of mechanisation; and the Ministry for Education must certainly be concerned with the technical education of a College affiliated with the University of London and training candidates for science degrees of the University. Thus no fewer than five ministries are more or less seriously concerned, and a conference as suggested of the Ministries of Agriculture, the Colonies, Health, War, and Education might yield some satisfactory results.

The progress of veterinary science has, moreover, introduced a new factor. The governing body of the profession—the Royal College of Veterinary Surgeons—has extended the course of training from four years to five years, and the change is expected to take place next year. This extension alone will increase the need for more accommodation and a larger staff at the Royal Veterinary College. If it is difficult to carry on the work under present conditions, it will become impossible under the new curriculum.

An International Veterinary Congress has just been held in London and upwards of two thousand delegates attended from all over the world. Most of them visited the Royal Veterinary College and must have wondered at the depressing and humiliating spectacle which is presented by this dilapidated structure, the premier veterinary college of the British Empire. It is to be hoped that the Government will realise its responsibilities in this matter, and take early steps to place the College on a sound basis both as regards buildings and finance.

Popular Science under Discussion.

A. WHAT have you there?

B. The eight books on popular science that I asked you, as an educated man disclaiming any special knowledge of science, to read and to discuss with me. They were written especially for people like you.

A. Have you read them too?

B. Well, I have to review them for NATURE; and I am reasonably conscientious. A discussion with you might give me some useful ideas for the review.

A. I am honoured. But how shall we begin? The books do not fall into any special order.

B. Shall we take them as they come? Here is Keyser's "The Pastures of Wonder", which explains the philosophy of mathematics, and bases on that a philosophy of science. I suspect you found it heavy going.

A. I must confess I did. I struggled along to page 36, where I met my Waterloo: "If a pro-

position P is such that to assert it is equivalent to asserting that a proposition q is logically deducible from a proposition p, or— what is tantamount—that p implies q, then P is a hypothetical proposition ; in the contrary case P is a categorical proposition ".

B. I sympathise with you. In no sense of the word can logic or the theory of mathematics be made popular. But I strongly recommend Section 2 of the book, in which Keyser deals with the realm of science. You will follow most of it in spite of your disaster with page 36, and enjoy, I hope, the courageous examination of the veiled antipathy between the scientist and the philosopher—a conflict due, of course, to differences in temperament, not in ideals.

A. You encourage me. I like the feel of the book - its binding, paper, and the excellent print. But isn't it somewhat dear at 14*s*. ?

B. American books are always expensive.

A. Ah ! that's due to protection.

B. You forget. I am reviewing for NATURE, not for the *Spectator*. Here is the next book : " Modern Science ", by J. Arthur Thomson. There was no difficulty here, I imagine ?

A. None at all. Thomson's books—I've read most of them—never give me the impression that he is writing down to my level, and yet, of course, he is.

B. Few people have that happy gift, and Thomson is one of them. But I must be critical if possible. What did you think of the diagrams ?

A. I don't remember them particularly, except, of course, those illustrating some definite point, such as the development of a coral.

B. Exactly. I cannot feel that the complex relations between organism and environment, for example, are much illuminated by a few concentric circles with arrows of different lengths scattered over them. But I mustn't be dogmatic ; they may serve as mnemonics. Now for the next book : " Rhythms of Life ", by Fraser-Harris.

A. That ranges over almost as wide a field as Thomson's book. I like the manner in which all kinds of out-of-the-way information has been welded into a coherent whole. The chapters on " Suspended Animation " and " How many tastes have we ? " show that particularly well.

B. " Rhythms of Life " deals mainly with biological subjects. It is, I see, in the same series as J. G. Crowther's " Short Stories in Science ", which is largely concerned with physics and chemistry. I shall be most interested in your views on Crowther's book.

A. Why that one more than the others ?

B. Well, Crowther implies in the preface that he is a layman in science. That brings up the question whether science for the general public is presented better by laymen or by professional scientific workers. In other words, should the author be a man who knows his subject or one who knows his audience ?

A. I don't quite follow you. Surely every author should know his subject ?

B. Obviously. But among men of science, ' knowing the subject ' implies the initiation and control of original research work. So I will put my question in this form : Is the discoverer the best man to explain his own discoveries, and those of others, to the educated public ?

A. An awkward question. I am not competent to answer it. But I thoroughly enjoyed Crowther's book.

B. Frankly, so did I. If every layman-author understood as much of science and wrote as well as he does my question would be answered. Incidentally, Crowther devotes his last chapter to this very question. He argues that the majority of men of science should avoid non-technical exposition, and bluntly says : " a scientist who chases both literary and scientific images is endangering his scientific career ". The argument is cogent and merits the careful attention of all scientific workers who hanker after the fleshpots of journalism. But we cannot spend more time on that point now ; we have still four books to deal with. I suggest we take Millikan's " Science and the New Civilisation " next.

A. That will be most appropriate, for I can see it is an exception to Crowther's general argument. Although the book is a collection of various addresses, and therefore discursive in parts, there is an unmistakable air of authority about it ; Millikan knows what he is talking about.

B. Yes, and knows how to say it, too. In fact, I wish he had not used italics so freely in places, for his literary style does not need such artificial aid. Take, for example, his address on the relation of science to industry given to the hard-headed business men of the New York Chamber of Commerce. That speech must have been a triumph ; yet in its printed form it contains scarcely any italicised words. Well, the next book also hails from the United States : " Popular Research Narratives ", vol. 3, with the comprehensive sub-title, " Fifty Brief Stories of Research, Invention or Discovery, directly from the ' Men who did it ' ".

A. That left me with rather a dizzy feeling. From "Distances of the Stars" to "Cast Iron Pipe" and thence to "Wealth from Cornstalks"—to mention three typical examples—is rather a big jump; and an average of only three pages for each account gives the book a hurried, breathless atmosphere.

B. It was written for the American public, which has an insatiable appetite for concentrated information, and has no time to waste on literary trimmings. This book undoubtedly meets that demand; and it has given me, with my sneaking admiration for the crude vivacity of American phraseology, another addition to my collection. It is the opening of the article on moulding rubber with electricity: "Man has long used rubber to keep electricity where it belongs". I could quote some others, but I know you detest them. So let us pass to "The Men Who Found Out", by Mrs. Williams-Ellis.

A. I had no opportunity of reading that; my children discovered it and stuck to it firmly.

B. I don't think we could find any higher tribute than that, but I would like to add one thing. These stories were first given as broadcast lessons to young children. A mere transcription of such lessons into book form would make a poor book, for the technique of broadcasting to children, and of writing for them, are two very different things. Mrs. Williams-Ellis evidently appreciated this point, and she has produced a most enjoyable book. Her descriptions of Harvey, Faraday, Pasteur, and other scientific pioneers will set many youngsters on the path of hero-worship.

Now we come to the last book: "This Bondage", by Commander Bernard Acworth. Well?

A. Well?

B. From which illuminating remark I judge that the Commander has not had an enormous success. What was the trouble?

A. I had the uncomfortable feeling that the author had a few axes to grind. He has no use for airships, aeroplanes, scientists, Dean Inge, and the Bishop of Birmingham; and all this is based on his demonstration that the track of a bird or insect in flight is inevitably affected by air currents.

B. We can dismiss the axe-grinding with the cynical remark that it would have been better had he collaborated with one of the despised scientists. With regard to the effect of wind velocity on the flight of birds, which is ostensibly the main purpose of the book, I feel unkind enough to say that the author has discovered—somewhat belatedly—the parallelogram of velocities and is anxious to tell the world about it. He should have confined himself to that, for, as he justly points out, some naturalists talk a lot of nonsense on the subject.

Now, having completed our discussion of these books, I propose not to write a formal review, but to give instead the gist of our conversation.

B. A. KEEN.

Life and Physics.

Beyond Physics, or the Idealisation of Mechanism: being a Survey and Attempted Extension of Modern Physics in a Philosophical and Psychical Direction. By Sir Oliver Lodge. Pp. 172. (London: George Allen and Unwin, Ltd., 1930.) 5*s*. net.

SIR OLIVER LODGE could not write a dull or uninteresting book if he tried. In this book he puts forward his own views so modestly and discusses the view of others so lucidly and fairly that it is an ungrateful task to criticise him. At the same time he states the problems so fully and candidly that he provides all the material needed for criticism. His main object is to find a place for life and mind in the world of physics, or rather behind the world of physics as a primordial ingredient of the universe. In the reviewer's opinion he is looking in the wrong direction for the solution of the problem, and if his theory were true the problem would be of its very nature insoluble. Of course the problem may be insoluble.

The nature of the argument can perhaps be made clear by an analogy. It is said that a tourist once got into a cab at Cambridge Station and asked to be driven to the University. The cabman after much thought and with some hesitation stopped midway between the Senate House and Great St. Mary's and said that that was the best he could do. He realised that the University is not, as the tourist imagined, a physical object. Neither is it a set or class of physical objects. The class of all members of the University plus all inanimate objects such as buildings, books, and so on that belong to it, is not in itself the University. The University is rather a system of relations among members of this class and many other physical objects too numerous to mention, but including the King, his Parliament and all his subjects, in accordance with whose laws the University continues to exist. What constitutes the University and why we give it a single name is that there is a unifying principle among these relations. In a word, the University is an organism, or a system of organisation among a group of physical objects, which are in a more or less intimate way its organs. The

Vice-Chancellor is one such organ, but so also to a less degree is the cheque for five guineas sent to an external examiner. From the ordinary point of view of physics, which is not unlike that of the tourist, the University is a pure nonentity.

The University in its relations to physical objects is taken as being analogous to the life or the mind of a man in its relations to his body and physical environment. There is nothing novel in this statement; the matter has come to the fore recently in the writings of several well-known philosophers, and it is all excellently discussed by Sir Oliver Lodge. But he is not content to say simply that the life of an organism *is* the unity or principle of its organisation; he looks for something physical or quasi-physical to be its basis. His answer is (to put it crudely) as though the cabman had said to the tourist: "All these buildings and people you see round you being physical objects are ultimately only sets of group waves having relatively slow velocities, of the order u. Their constituent waves in the ether, which have higher velocities v such that $uv=c^2$ where c is the velocity of light, *are* the University. These constituent waves, though they possess no energy, control the direction of propagation of the group waves, which possess all the energy and consequently are what you perceive. But I can assure you that though the constituent waves are not accessible to observation they pervade the whole ether, and the specific University of Cambridge waves are specially concentrated on this spot."

This is meant seriously as a *reductio ad absurdum* argument. As we all admit we know little about life and mind we are ready to believe almost anything about them. It is easier to see the fallacy of a theory if it is applied to a similar type of organisation we do know something about, though there is the risk that the analogy may be misleading. In this case the analogy is of course imperfect, but it is not likely to be seriously misleading, because practically all we know of life from the physical point of view is that it is a process of organisation among material objects.

The fallacy (as I believe it) that Sir Oliver Lodge has fallen into is a common one. Everybody sees that life and mind are not physical objects or things related in any simple way to physical objects, therefore they either say that there are no such things or try to discover something quasi-physical to fill the gap. Most of the traditional theories of life and mind are of this type. The savage and the child cannot believe in an entity which is not a physical object, and the difficulty lurks at the back of the minds of all of us. Even Sir Arthur Eddington inclines in this direction when he would base spontaneity and freedom on the supposed indeterminism of intra-atomic processes, and Sir Oliver Lodge very properly criticises him for it.

Up to the present time physical theory has developed on analytic lines. Where the behaviour of aggregates has proved too complex for study they have been analysed into their components, and it has been assumed that the behaviour of the aggregates can be found by compounding in some simple way the behaviour of the components. The other type of aggregate that has been dealt with is the random aggregate to which the theory of probability can be applied. The great triumphs of physical theory have been in the treatment of random aggregates on one hand and of 'microscopic' transactions on the other. Organised aggregates have until recently been left alone. If the essential character of living things lies in their mode of organisation rather than in the nature of their parts, we can infer from the failure of physics to discern the nature of life among macroscopic objects that it is useless to look for it among molecules and atoms or electrons and protons, still more so in a hypothetical underlying ether. If you cannot see the design of a house in the pile of bricks dumped on the site, still less can you see it in the clay the bricks were made from. It may be mentioned in passing that the biologist has for the most part been confined to using the tools that physics has provided, and this is his excuse for having gone such a little way with such great efforts. The psychologist labours under similar but even greater difficulties.

There is evidence, as indeed Sir Oliver Lodge points out, that the physicist is beginning to consider the problems of organisation. Atoms are evidently organisms of electrons and protons, not aggregates in the simple sense. Again, a crystal is an organism of atoms of a very elementary kind. It is possible that from the study of these simple cases a physics of organisms will develop to supplement the classical physics of mere aggregates; and thereby new and superior tools will be put into the hands of the biologist for the study of higher grade organisms. On the other hand, it is possible that the human intellect will not be able to advance much beyond the classical analytical procedure. However, the problem does not appear to be inherently hopeless.

The suggestion that the nature of life and mind is to be sought in some property or process of the ether refers the problem to something outside the range of ordinary experience or knowledge. Sir

Oliver Lodge admits that no perceptible effect, however small, which can be attributed to the ether, has yet been found. He says (p. 100): "We may not be able as yet to measure motion except with reference to other pieces of matter, but some day I hope it may be measured with reference to the ether; . . ." If the principle of relativity is correct this hope cannot be realised: if it is false the probabilities are still all against it, seeing how hard physicists have tried to realise it and failed. As things stand at present we can assert anything we like about the ether, but nothing we assert will enable us to infer anything definite about any perceived or perceptible event. It was pointed out long ago by Leonardo da Vinci that valid scientific knowledge must begin with what is experienced and in the end point to something that can be experienced.

In the whole material universe life appears as something accidental and trivial. It needs very special and inherently unlikely combinations of circumstances for its development. So far as we know, it emerges only for a little while on one obscure planet. To say that the ultimate basis of life is something inherent in the constitution of the physical world makes the problem more difficult. If the seeds of life occupy all space and time, why are their flowers so few and brief?

To us as living and conscious beings the most important aspects of life and mind, the aspects that interest us, are not to be described in terms known to contemporary physics. So far as they can be described at all, it must be in terms of value, of praise and blame, of desire and aversion. It is conceivable that a system of knowledge might be built up from the general and abstract basis of physics to give an adequate account of life and mind, but it will need to include many elements not originally given in that basis. It is scarcely conceivable that a theory that uses only the most abstract and general physical terms can answer the questions about life and mind we are most concerned to ask.

A. D. Ritchie.

Savage Life and Thought.

Orokaiva Society. By F. E. Williams. Pp. xxiii + 355 + 37 plates. (London: Oxford University Press, 1930.) 25*s.* net.

Mr. F. E. Williams, the Government Anthropologist of the Territory of Papua, has given us in "Orokaiva Society", a book that will be of great value to ethnologists, to psychologists, and to those interested in administration. His excellent previous book "Orokaiva Magic" (1928) should be read in conjunction with the new one, as together they afford an illuminating study of savage life and thought. It is not too much to say that this combined work is one of the best that has been written about a particular group of peoples, for it not only gives detailed and well-illustrated accounts of the multifarious aspects of native life and the things that are made, but, what is of special value, the conclusions of a thoughtful investigator who has had, and made full use of, exceptional opportunities.

The useful, though obscure, name of Orokaiva is given to the group of tribes who inhabit the northern division of Papua from the lower Eia River (8° S. lat.) to Oro Bay, north of Hydrographers' range and inland for a distance of thirty miles or more. They are Papuan-speaking peoples with a fairly uniform culture which, on the whole, resembles that of many parts of New Guinea, but there is a notable difference between the northern and southern groups. The former includes the Aiga, Binandele, and Tain-Daware, and is characterised by numerous and remarkable dramas (at which very small drums are employed) which seem to replace the use of the bullroarer and ritual flutes in the initiation ceremonies of the southern tribes and in those of other tribes to the north and north-west.

All the tribes perform certain ceremonies, which are virtually *rites de passage* to convert the candidate, usually about the age of puberty, into a 'new child'. As among the Marind-anim of the extreme south-west of New Guinea, both sexes are initiated together. Those of the southern group are interned in a specially built house where they are introduced to the spirits of the dead, who are supposed to emit the noises caused by the bullroarers and flutes, and they are subjected to ill-treatment and terrifying experiences. The novices are completely covered with hoods of barkcloth, and the fathers and mothers entreat the spirits not to devour their children. Then follows a long period of seclusion in the special house, the avowed object of which is to make the children grow big and well-conditioned. They are taught to be honest, obliging, and diligent, and how to play the flutes. The end of this period is marked by a spectacular display; each novice is invested with a feather headdress which had been worn by a man who impersonated a spirit, and some of them, but not all, are adorned with a valuable ornament, the possession of which involves certain ethical obligations, and formerly in some cases it constituted the

distinctive badge of a homicide. Then follows promiscuous intercourse (on this occasion only), but not by the novices. A small rite releases the taboo on the mother's cooking, and a mixed stew is brewed and, after the novices are fumigated in its steam, they partake of it and may then resume full diet; this last rite is to prevent bodily deformities. It may be pointed out that there is a remarkable general similarity between these customs and those which obtain among the peoples north of Huon Gulf, and to a somewhat less extent to those of certain tribes about the Fly and farther west, all of which point back to an ancient cult of a monster or ancestral spirit who devours the novices.

A curious example of native psychology is found in what is termed *meh*, a feeling of shame, humiliation, and contrition. An Orokaiva who has been wronged is not only sorry for himself but he also wants others to be sorry for him, and particularly the man who has wronged him. Such a man will destroy his own property, run away from home, deliver himself up to an enemy tribe, or even hang himself on a tree, for the Orokaiva is very prone when his feelings are hurt to punish himself instead of the man who has hurt him, or rather by punishing himself to take revenge upon the other party or in order to make him feel *meh*. The state of anger and self pity endured by the wronged man has a definite name, *sisira*, and by his action the culprit is put to *meh*, and very unpleasant he finds it, as apart from his own sense of shame he is the object of public reprobation.

The foregoing will suffice to indicate the interest and value of this careful piece of work.

A. C. Haddon.

Aviation and Meteorology.

(1) *Exploring about the North Pole of the Winds.* By Prof. William Herbert Hobbs. Pp. viii + 376 (24 plates). (New York and London: G. P. Putnam's Sons, 1930.) 5 dollars.

(2) *La navigation aérienne transatlantique.* Par Capt. G. Voitoux. Pp. 144. (Paris: Société d'Éditions Géographiques, Maritimes et Coloniales, 1930.) 28 francs.

(1) PROF. HOBBS'S book is a well-illustrated and entertainingly written account of three expeditions under his leadership between 1926 and 1929 to the south-west coast of Greenland. The expeditions were organised as a University of Michigan enterprise, and were for the purpose of studying the wind system controlled by the Greenland ice-sheet. An aerological station was established on Mt. Evans at a little above 1000 feet, some distance inland from Holstenborg in about latitude 67° N., and functioned uninterruptedly for two years. The staff of the observatory had to be changed at intervals, and though the latter has now been closed, everything has been left in readiness for a resumption of activity in the future. A large number of balloon ascents were made from here and at encampments elsewhere in this part of Greenland in addition to the usual ground observations, and several sledge journeys were conducted to the inland ice-sheet.

The observations appear to confirm the prevalent theory that the winds blow outwards from the ice-dome and inwards at higher levels. Prof. Hobbs, of course, has always been a champion of the Glacial anticyclone, and it is satisfactory to find his views substantiated in the chapter on the "Winds from the 'Great Ice'", wherein he shows that the entire circulation over the ice-cap is similar to the outline of an hour-glass. What serious meteorologists will miss, however, is something like a complete log of the actual daily observations which would give them an idea of the extent of the variations from these standard conditions. The southern part of Greenland has a heavy snowfall, which certainly points to temporary influence by the Icelandic depressions. The expedition appears to have met with an abnormally mild winter on the south-west coast in 1927–28, when föhn winds, raising the temperature at times above 40° F., would cause a complete clearance of the scanty snowfall. Storm winds are recorded of the order of 120 miles an hour, rendering navigation difficult and perilous in the long winding fjords. One is struck with the frequent reference to rain instead of snow in the summer months along this part of the Arctic circle, and wonders whether this is usual. The reader will, in fact, wish for a little more discussion of the weather events experienced in relation to general climatic conditions in Greenland.

Prof. Hobbs considers that Mt. Evans has unique advantages for a flying base on a proposed northern air route across southern Greenland between America and Europe. Along the route from Mt. Evans eastwards to Angmagssalik the ice plateau has a maximum altitude between eight and nine thousand feet, and it should be possible for the aviator to navigate safely by the use of his altimeter above the smooth snow surface.

On the human side the book is pleasant reading, and there are naturally some exciting adventures to record.

(2) Capt. Voitoux's book, if somewhat close reading, affords nevertheless a very intelligible account of North Atlantic weather in relation to aerial navigation. It is based fundamentally on a full year's observations from vessels at sea, and in order that the reader may have, so to speak, all the author's cards on the table, these observations are reproduced in the form of a log covering 366 daily observations over the period May 1, 1927–April 30, 1928. This shows the positions of the centres of high and low pressure (produced also on a handsome map of the North Atlantic), the direction and force of the wind, and the state of the weather. After a general explanatory account of the regimen of North Atlantic wind and weather, a number of weather situations that occurred during the period are carefully analysed with the aid of the weather charts of the French Meteorological Office, and opinion expressed as to what, in the particular conditions, should be an airman's route across the ocean, having regard first to safety and then to speed.

Wind according to its relative angle can be helpful to aircraft, but is more usually prejudicial even if not actually dangerous, whilst storms and all atmospheric conditions that the author comprises under the term 'intempéries' are always inimical. That the North Atlantic is a stormy ocean is brought out in a way that cannot fail to impress the reader. It appears that a ship crossing the ocean must practically always reckon on encountering storm winds on some part or other of the voyage even in summer, and that in sixteen years a Commandant de Transatlantique only once enjoyed fine weather the whole way. The mean wind velocity is about 40 kilometres per hour, a figure based upon a great number of observations from all parts of the North Atlantic, including calms and tempests. Out of 5782 ships' observations, calm is noted only for 111 positions on 86 different days, but on these 86 days winds of varying strength were experienced on other parts of the course.

A contrast is drawn between the conditions of the seaman and the airman over the ocean. The seaman has his navigation charts to rely on, and whilst the marine currents can only deflect him from his course by relatively small known amounts, the effect of the air currents on the drift of his vessel is insignificant. The airman's case is very different. For him the most advantageous route to follow is constantly changing from day to day, or even from hour to hour; the air currents may help or hinder him in a way he does not immediately appreciate, and may deflect him from his course by an amount ten, twenty, fifty times greater than is the case with the seaman.

The aviator's chart cannot, unfortunately, indicate the mobile dangers of the atmosphere as the mariner's chart does the fixed dangers of the sea. It is nevertheless essential that the airman should study the behaviour of cyclones and anticyclones, and learn to take the favourable side of these systems, for on this procedure depends success or failure, safety or death. Reference is made, further, to the vast lonely tracts of ocean even in the frequented liner routes, giving poor chance of succour to an airship or aeroplane in distress.

Capt. Voitoux writes throughout with a strong note of caution, and deprecates reckless adventures of the kind that inevitably spell disaster. He quotes expert opinion to the effect that in the present state of the science of aviation the flight across the North Atlantic from west to east is almost impossible in the higher stormier latitudes. Whilst fully endorsing all the caution that the author enjoins, we must yet ask whether there is really much justification for supposing that the *present* state of the science in question will obtain much longer. With all that has already been achieved, it seems to us disproportionate to think that the time will be long before the flight across the Atlantic becomes a commonplace in either direction. We must also remember that all mechanical progress has been purchased at the cost of a toll of human life.

Our Bookshelf.

Shells of the Tropical Seas. By Ida Colthurst. Pp. iii + 13 + 6 + 6 plates. (Calcutta and Simla: Thacker, Spink and Co., 1930.) 4.8 rupees.

THE author has a pleasant way of writing about what is usually made dull. She might quite well expand her pamphlet into a short volume to re-awaken interest in shells. A little story is told us about most conspicuous families, their varieties of shells and their beauty and interest being brought out with subtlety. The author should visit Tuticorin, Ceylon, or the Andamans, and collect her molluscs on the reef flats, if she wants to make the attractive picture of the living animals that the present generation requires. We want to know much more about the *cilia-moving forms* and the mode of feeding of bivalves. We wonder whether pressure is of any importance in the distribution, and surely diminution of light is only indirectly so as inhibiting the growth of the plants on which they feed. There is no laminarian zone round southern India, being replaced by the coralline zone, which extends to about 30 fm., where it is stated that it commences. Nor is any evidence given that the pearly nautilus or any other existing animal lived

in palæozoic times. To say nothing about the squids is extraordinary.

It is foolish to-day even for a " Diocesan Press " to talk about "the book of creation" and "the power which makes the planets go"; the religion which prints such worn cliches can only be laughed at by educated Indians; it is best to take advice from S. Athanasius, who is quite clear on this subject. Why drag in a Laccadive sea of no particular interest and certainly not a "sea"? An author must handle oysters and mussels before they can be written about, and why not say how the starfishes of tropical seas kill oysters? Most shelled Buddhas are in freshwater mussels—and Bideford bridge is not at the junction of the Taw and Torridge. The illustrations are well chosen and badly reproduced, but clearly the book is not intended to sell, for 23 pages of letterpress with 6 half-tone plates will never find a wide market at 6s. 9d., taking the rupee at 1s. 6d. Perhaps some member of the staff of the Calcutta Museum might supply the facts for a book and Miss Colthurst the indispensable vivacity; it would do both good.

British Museum (Natural History). British Antarctic (Terra Nova) *Expedition, 1910. Natural History Report. Zoology*, Vol. 5, No. 5: *Coelenterata.* Part 5: *Hydroida.* By A. Knyvett Totton. Pp. 131-252 + 3 plates. (London: British Museum (Natural History), 1930). 15s.

EIGHTY species of hydroids were obtained by the *Terra Nova* expedition, of which four only belong to the Athecata, a discrepancy which is not explained. Their geographical distribution is not considered, but judging from the list of stations there would seem to be about the same number of species on suitable bottoms from the surface to 300 fm. The present treatment of a group of beautiful little animals is in a hard systematic strain. The author restrains his soul, for there is scarcely a reference to, and not a single drawing of, any polyp. We wonder whether the classification almost solely on the external skeleton is sound and how far it is going to lead us. The British Museum alone of institutions in Great Britain has the material necessary to answer this question. Like all its publications, the work is well reproduced. We would, however, ask the director to consider the advisability of enforcing standard magnifications in all figures, one genus showing no less than thirteen different magnifications in the plates.

The Colloid Chemistry of Rubber. By Dr. Paul Stamberger. Pp. vii + 80. (London: Oxford University Press, 1929.) 6s. net.

THE Oxford University Press has already published under the title "The Colloid Chemistry of the Rubber Industry" a small volume (of 56 pages) by Dr. E. A. Hauser, professor of colloid chemistry at the Massachusetts Institute of Technology, as a report of lectures of a series instituted by Mr. Patrick Gow. The present volume contains the subject-matter of lectures of the same series, given at University College, London, in November 1928, under the title "Colloid Chemistry and its Relation to the Rubber Industry". The first chapter is a general introduction to the study of colloid chemistry and colloids, the second chapter—on the colloidal properties of rubber—deals with rubber latex and its industrial applications, the third chapter —on lyophile colloids—deals with crude rubber and its solvation, whilst the two remaining chapters deal mainly with the 'compounding' of rubber with 'fillers' of various types, and with its vulcanisation, but also include a section on the synthesis of rubber, and an account of current views on the structure of rubber. The book will appeal most strongly to those who are concerned with the manufacture and use of rubber, but is written on such broad lines that it may be read with interest by other students of colloid science. The volume is presented in a very attractive form and at a reasonable price, and it should have a wide circulation.

Medicinal Herbs: and How to Identify Them. By Richard Morse. (The "How to Identify" Series, No. 21.) Pp. 64. (London: The Epworth Press, 1930.). 1s. 6d. net.

IN this little book of 64 pages, descriptions are given of twenty-seven commonly found wild plants that either are or have been used for medicinal purposes. An illustration is given of each plant described, and the descriptive matter includes a description of the plant in popular language, particulars as to where the plant is to be found, and an account of its medicinal properties and uses. The author does not claim that his work is exhaustive in any direction, his object in writing the book being to provide a pocket guide which would enable people on country rambles to learn something about some of the plants they pass.

The Trauma of Birth. By Otto Rank. (International Library of Psychology, Philosophy and Scientific Method.) Pp. xv + 224. (London: Kegan Paul and Co., Ltd.; New York: Harcourt, Brace and Co., 1929.) 10s. 6d. net.

LIKE so very many examples of psycho-analytic writing, this work is almost purely speculative and the author allows himself to be carried away by theorising, seeing and believing what he wishes to see and believe. His main theory is that the trauma of birth is the most deeply repressed portion of the mind. Anxiety and other symptoms are attributed to this birth trauma. From a therapeutic point of view, experience with schizophrenics leads one to be very sceptical of analysis as a procedure of any value.

The Truth about Mind Cure. By Dr. William S. Sadler. Pp. viii + 206. (London: George Allen and Unwin, Ltd., 1929.) 5s. net.

"THE Truth about Mind Cure" is a simple and straightforward account of elementary psychotherapy by an American physician. He deals with his subject in a popular way and certainly presents a very readable account for the lay reader. The advice is sound and may do good to many lay people who are interested enough to read it.

Letters to the Editor.

Spontaneous and Induced Magnetisation in Ferromagnetic Bodies.

ACCORDING to Weiss's well-known theory, a ferromagnetic body in the absence of an external magnetic field must be spontaneously magnetised in such a way that the direction of magnetisation varies in an irregular manner in different portions of the body. It was originally assumed by Weiss that these portions coincide with the minute crystals of which the body is built up. That this is not so is clear from the fact that spontaneous magnetisation (as revealed by the existence of a Curie temperature) is present also in single crystals. We are thus forced to assume that a moderate-sized single crystal of a ferromagnetic body consists of a number of 'elementary magnets' the resultant magnetic moment of which vanishes. This spontaneous subdivision of a ferromagnetic body into elementary magnets can be interpreted both qualitatively and quantitatively in the following manner.

In the absence of Weiss's 'quasi-magnetic' forces (forming the molecular field and depending, according to Heisenberg,[1] on the quantum exchange effect) the individual magnets (electrons) would tend to orient themselves in such a way as to insure the disappearance of the resulting magnetic moment in every unit cell of the crystal-lattice—just as in the case of a crystal built up of electric dipoles.[2] The usual conception that such dipoles—whether electric or magnetic—tend to orient themselves in the same direction is wholly wrong, the minimum value of their mutual potential energy corresponding to a state of electric or magnetic neutralisation, that is, to the disappearance of the resulting polarisation in the least possible volume.

In the case of a ferromagnetic body, there are, on the other hand, the quasi-magnetic forces, which at small distances are much more powerful than the Coulomb ones and tend to orient the individual magnets in exactly the same direction. This struggle between magnetic and quasi-magnetic forces results in a compromise, the individual magnets uniting in elementary 'bunches', which owing to Coulomb forces acting between them are oriented in a way similar to those in which the individual magnets would be oriented in the absence of quasi-magnetic forces. This spontaneous magnetic splitting can be compared with the splitting up of a large mass of a liquid into single drops, under the condition that the surface energy of the latter should be compensated by some sort of mutual potential energy quite different from the energy of the ordinary cohesive forces.

In our case, the work done against the quasi-magnetic forces in the process of splitting up of a uniformly magnetised body into single 'drops', which magnetically neutralise each other, is equivalent to a surface energy of the amount $\frac{1}{2}AI^2s\delta$ per drop, where I is the original magnetisation of the body (equal to the magnetic moment of each drop M, divided by its volume v), A is the constant of Weiss's molecular field, s is the surface of a drop, and δ the thickness of its surface layer, that is, the range of the quasi-magnetic forces; δ is obviously of the order of magnitude of one atomic distance. The Coulomb potential energy per 'drop', corresponding to the work done by the magnetic forces in the process of 'disorientation', is equal to $-\frac{\alpha M^2}{l^3} = -\frac{\alpha I^2 v^2}{l^3} \cong -\alpha I^2 v$, where l is the distance between the centres of the neighbouring drops (since it is of the same order of magnitude as its linear dimensions, $l^3 \cong v$) and α a numerical coefficient; in Born's theory of a dipole lattice (*loc. cit.*) $\alpha \cong 1{\cdot}5$. We thus see that the increase of quasi-magnetic energy due to splitting is just compensated by the decrease of magnetic energy when $\frac{1}{2}AI^2s\delta = \alpha I^2 v$, that is, when the linear dimensions of the 'drops' $\frac{v}{s} = l$ reach the minimum value $l_0 = \frac{A}{2\alpha} \cdot \delta$. Since Weiss's constant A is of the order of magnitude of 20,000 (for iron), we have approximately $l_0 \cong 10{,}000 \cdot \delta \cong 10^{-4}$ cm. This shows that *the elementary regions of spontaneous magnetisation must contain at least* $(l_0/\delta)^3 = 10^{12}$ *atoms.*

To find the average size of these regions or 'magnetic drops', we must consider the minimum value of the quasi-magnetic and magnetic energy of a body consisting of a given number of atoms as a function of the linear dimensions of the drops l. Denoting the volume of the body by V, we get for the total quasi-magnetic surface energy $U_1 = \frac{1}{2}AI^2s \cdot \delta \frac{V}{v} = \frac{1}{2}AI^2\frac{\delta}{l} \cdot V$ (it may be remarked that this energy can be regarded as the quasi-demagnetisation energy of the 'interspaces', connecting the uniformly magnetised elementary regions of the body). As to the total magnetic (Coulomb) energy, we must add to the volume part of it $U_2 = -\alpha I^2 v \cdot \frac{V}{v} = -\alpha I^2 V$, which does not depend upon the size of the drops (if the volume of the interspaces is neglected with respect to V), the surface energy of the whole body, due to the incomplete 'screening' of the surface drops. For this surface energy we get in the same way as for the surface energy of an electric dipole substance the expression $U_3 = \alpha' I^2 l \cdot S$, S being the surface of the body and α' a numerical coefficient of the same order of magnitude as α ($\alpha \cong \alpha' \cong 1$). The minimum value of $U = U_1 + U_2 + U_3$ is determined by the equation $\frac{dU}{dl} = 0$, which gives $\alpha' I^2 S - \frac{A}{2} I^2 \frac{\delta V}{l^2}$, $l^2 = \frac{A}{2\alpha'}\delta \cdot \frac{V}{S} = l_0 \cdot L$, where l_0 is the above defined minimum value of l and $L = V/S$, the linear dimensions of the whole body. For a body of moderate size we thus get $l \cong 10^{-2}$ cm. (It must be, of course, supposed that $L >> l_0$.)

The fact that the mean size of the 'magnetic drops' depends upon the size of the whole crystal seems at first sight somewhat bewildering. It should be mentioned, however, that a similar fact is met with in various other problems; thus, for example, in the Debye theory of specific heats of solid bodies, the wave-length of the elastic waves extends on the long wave-length side up to the linear dimensions of the body, and the total number of normal vibrations within a given frequency interval is proportional to the body's volume.

It is probable that actually there are to be found in a ferromagnetic body 'magnetic drops' of various size—from the smallest one (l_0) and up to 10^{-3} cm. or even more. Experiments on the Barkhausen effect by Bozorth in fact give evidence of drops of such large dimensions. An important corollary from the above considerations which should be emphasised here is the fact that very small (colloidal) particles,

the linear dimensions of which do not exceed $l_0 = 10^{-5}$ cm., can never split into drops, and must therefore be permanently magnetised.

Another important consequence is the absence of remanent magnetisation in ferromagnetic single crystals of an ordinary size and, more generally, the absence of hysteresis in such crystals as this was actually shown by Gerlach. It should be remembered that hysteresis is a direct consequence of the Langevin-Weiss theory when applied (as is usually done) to the individual magnets. Actually, an external magnetic field acts on each drop as a whole, the magnetic moment of the drop being determined practically by Weiss's molecular field only, and thus being a function of the temperature alone. We have not yet been able to derive the exact formula giving the dependence of the observed induced magnetisation I' upon the field strength H and the temperature T. According to Weiss's empirical formula, one has, for large values of H, $I' = I(T)(1 - a/H)$, where $I(T)$ is the saturation magnetisation for a given T, and a is a constant independent of the temperature. Our 'drop' picture of a ferromagnetic body leads to an expression of the type $I' = I(T) . f(H)$, where $f(H)$ is a function of H only, different, however, from Weiss's $(1 - a/H)$. It may be observed that the process of orientation of the 'drops' by the magnetic field must be accompanied by their gradual fusion, the whole body becoming a single large drop when saturation is reached.

The phenomena of retentivity and hysteresis which are observed in ordinary ferromagnetic bodies (not single crystals), appear to be connected with the inner stresses characteristic of their structure. It is possible that they are due to the formation of strongly prolate drops arranged in chains (a disposition which is not consistent with the principle of minimum energy within a single crystal). We hope to consider these questions at a greater length in a future communication.

Space and Matter.

"SOMEWHERE in the absolute elsewhere."—*Punch*, July 9.

> "My interest in Nature
> Is rather based, I feel,
> On freaks of nomenclature
> Than scientific zeal."

Reading these lines, I feel that not a little truth is expressed in poetry, particularly when published from Bouverie Street (July 16). It is true

> "I sometimes like to ponder
> Upon the proper mien
> For coping with a condor
> Couched on the nineteenth green:
> Or else a capercaillie
> Conversing in Old Bailey
> About the works of Paley
> With our tremendous Dean."
>
> Or talk to Ol'ver Lodgey
> About his great big body,

especially when he tells us (July 5) that "Matter is inert; space is energetic. Matter *does* nothing". Like another Bellman,

> "He has bought a large map representing the sea
> Without the least vestige of land."

Perhaps history will be repeated:

> "This was charming, no doubt: but they shortly found out
> That the Captain they trusted so well
> Had only one notion for crossing the ocean
> And that was to tingle *his* bell.
>
> "He was thoughtful and grave, but the orders he gave
> Were enough to bewilder a crew."

Apparently, matter is more window-dressing. Is not perhaps Sir Oliver a window-dresser? *Are* his doings, his writings, *nothing*? They seem to sell. Do they just come out of space? He more than fills a stall and definitely fills space when he jazzes. Would there be no difference between his body and a sculptured likeness in stone from the 'point of view' of space? Is there really no hope for us bits-o'-chemists—is our occupation of structure-hunting gone? He would put matter 'on the dole'. Will he tell us: if not energetic, how does it smoke cigarettes, or is this a function of space? It seems now to be the universal habit: space, we suppose, must have its bad as well as its good habits.

I do venture to question my old friend's modern freaks of nomenclature—his contortions of our vulgar tongue. I have just received a company circular in which the chairman replies to a shareholder's question—"What do the complicated Resolutions really mean in plain and unmistakable language?" I should like to ask, what does Sir Oliver mean in terms of plain English? Is he merely breaking a lance on behalf of his beloved steel-hard ether or is he 'getting at us', in order to air his more than nebulous notion of a future life in space, whatever that may be?

'Science' is something that we are endeavouring (perhaps I ought to say, should endeavour) to pass on to the masses. It were time, therefore, that some protest were made against the language used by our would-be leaders:

> "They have wholly forgot (and it vexes me much)
> That English is what we speak."

The public is being played upon and utterly misled by the dreamery of the rival mathematical astronomers and physicists—not to mention the clerics who are touring to-day and raising the game of notoriety to a fine art. In rivalry to religious mysticism, a scientific pornography is being developed which attracts the more because it is mysterious—apparently the professors are seeking to outrival Mrs. Eddy. They have no regard for consequences. These may well be serious, as is shown by the way in which nonsense about the energy in a drop of water is being repeated everywhere—by law lords thinking of the world in 2030, as well as presidents of societies bordering on the learned, discoursing either of water or of the future of chemical industry—as if it were possible to make such energy available, a contingency which honest men know to be more than remote.

'Science' to-day is prostituted by over-speculation in public; no proper use is made of it to moral ends. Machinery is being made omnipotent: in fact, we need a new word: we no longer *manu*facture; not space but the machine does the work. Man certainly is not energetic. Whilst human beings are fast increasing in number, every attempt is being made to 'rationalise' them out of usefulness. We are even told that agriculture is soon to be handed over to a new synthetic agency—the craze to escape from Nature is upon us. Living matter will soon have nothing to do but lapse into space—we shall al

seek our fortunes 'somewhere in the absolute elsewhere'; in fact, be

"A pack of pure porbeagles,
For hunting of the Snark."

Is it that our make-up is such that we cannot be scientific—that we are perforce only religious?

HENRY E. ARMSTRONG.

Stability in Soap Films.

IN his letter to NATURE of June 28, p. 970, Mr. Lawrence has not, in my view, made the sandwich structure for soap films appear more likely, but has only discussed some necessary limitations to the layered arrangement that I suggested. One or two definite points may therefore be acceptable.

1. Surface layers are almost universal for solutions, but only soap solutions give stable mobile films. If their mobility and permanence is to be ascribed solely to the surface layers, these must be of surprisingly unique cohesiveness.

2. Such surfaces admittedly take time to form, especially in dilute solutions. The process of a slowly growing bubble may be sufficiently deliberate, but the 'throwing' of a film—described by Dewar as workable certainly up to a diameter of 19 cm.—takes only a very small fraction of a second. It would therefore seem that to persist, a film must be formed of material capable of being drawn into some initial structure; the nature of this is, I think, suggested in the definite boundaries which frequently appear, either in long-lived bubbles in the absence of convective disturbance, or in plane films during steadily maintained vertical motion, and in other gradations exhibited in films in a permanently liquid form (see Clerk Maxwell: "Scientific Papers", II. 397. Dewar: "Papers", II. 1341). This is very different from the abnormal solid stratifications depicted in the frontispiece to "Soap Films". The described crystallisation extruded into the original film and provided by solute from the surrounding Gibbs ring can, of course, only occur in tiny films and not over large areas; some of Perrin and Wells's films may be similar, but Perrin says of those last described (*Koll. Zeit.*, April 1930) that they are certainly liquid, and describes the means he took to satisfy himself about this.

3. It is obvious that a five per cent solution can only provide in any film a limited number of layers if these are to be close packed solute; the possible lamination of colloid threads or flakes would certainly be even more limited; and if instead of five per cent we consider a solution of 0·1 per cent (which Dewar found to give perfectly stable films) a statistical estimate such as that suggested would give only a fifth of a molecular layer in a 1000 $\mu\mu$ film. If we then assumed that the equivalent of two close packed layers is present as surface film on either side of this vestige, the disproportion of concentration between soluble surface and enclosed solution becomes miraculous, and how to maintain the supply for the reserve layer an embarrassment, even in such a thick film; reduce the thickness and therefore the available material to one-tenth to get to the order of a silvery film, and I think it may be agreed that we shall need to enlarge our conceptions beyond what close packed solute can provide. Hydration—or may I say 'hydrosolation'—may provide one clue: be it noted that the 'anchoring' of carboxyl groups, etc., to water must be by molecules or molecular groups, and not into an indefinite statistical 'surface' as is sometimes implied.

4. Soap films maintained in vertical motion by steady air jets continuously exhibit sharply defined colour tracks (Dewar: "Papers", II. Front.). Not only is there in such circumstances a main stream in rapid motion—at about one metre a second (*ib.*, 1376)—but the successive adjacent tracks move at different rates, so that the whole film is in continuous relative motion of distinct thicknesses. A similar discontinuous appearance is revealed by almost any horizontal film under microscopic examination (with a vertical illuminator). It is therefore evident that the soap film does not need to be a smooth sandwich.

5. The interfacial attractions that I suggest between self-cohesive layers would be successively equilibrated throughout the film, whereas an ordinary film of liquid without some structural cohesiveness must and does collapse under 'surface' tension despite the universally present adsorbed layer, admittedly because the inwards forces at the surfaces are not equilibrated. The word 'powerful' applied to the interfacial attractions may be misleading; but I see no reason why such layers (see Rideal: "Surface Chemistry", 1926, 91) though yielding to lateral displacements, should not be successively shed or aggregated in the relentless separation of the black. After Lyons's recent work on the variations with pH value of the submersion of oleic acid lenses (*Jour. Chem. Soc.*, April 1930) we may expect the pH value of a soap solution to influence or even control the intensity of aggregation by varying the interfacial or intramolecular attractions within the film. It is certainly to be hoped that the pH value will now be regarded as an essential part of the description of experimental soap solutions.

6. The 'black' area is the only portion of a soap film giving evidence of a close packed structure, because it is non-extensible (Dewar: II. 1197, also Clerk Maxwell: *ib.*, 398) except possibly in very dilute solutions which give misty greys rather than blacks (Dewar: *ib.*, 1345). The observed mechanism of the appearance of the black is by the separation of clots emerging (at greatly varying intensities) from the initial thick film (*ib.*, 1335). Fig. 1 shows (what

FIG. 1.—Development of horizontal soap film: slow aggregation of one 'black' layer on another, film still two-thirds coloured.

has never before been illustrated) that even this sometimes occurs in stages. The distinct character of the coloured area was early evident in the account of one of Dewar's 56 cm. black films (II. 1209). Wandering coloured clots on approaching the periphery are not absorbed into the 'Gibbs channel', as they would be with avidity if they were enclosed between elastic surface layers, but on the contrary divide and circulate in both directions, obviously because they are at the foot of the curved slope of the liquid ring of contact, and actually on the black film surface.

Such observations show that an examination of a directly accumulated mass of black film is very desirable. It should be possible by passing a clean glass rod through masses of black film as collected by Dewar in a 200-litre globe (*ib.*, 1210); or accumulating

a succession of films (drained by cellulose threads to blackness) in a McBain apparatus. Even more valuable would be a trial of the forces at the black boundary by the Langmuir-Adams method, using quite a small trough or film-frame in a moteless Dewar enclosure.

After years of observation I find it difficult therefore to accept that one oriented layer and one irregular reserve layer below this on either face, and nothing but chaos between, can explain the appearances presented by soap films, or maintain their tenacity under such conditions as have been described.

Daily Variations of Temperature.

IN the discussion on the "Irregular Variations of Temperature in London" (NATURE, 126, 61) the case of periods of several days was in question, and smoothed averages were taken. Some years ago I was attracted by the daily irregularities observed at Greenwich, in averages of fifty years, and compared them with those of other available records, Falmouth, Kew, Valentia, and Aberdeen. I wished to have included Buitenzorg, but the volume of records was missing from the Royal Society library.

The results are in the diagram (Fig. 1). The maxima will represent the true solar effect, as we do not know of any other cause of heat; all below the maxima must be due to some cause of deficiency. It will be seen that at the vertical lines (marked with the day-number in the year) each of the records shows a minimum; such a deficiency cannot therefore be due to a local cause. The only obvious cause would be the interposition of streams of minute asteroids in regular orbits. To study this farther would need the comparison of records from a large number of positions, over short terms of years, as orbits may shift by precession. The zodiacal light seems only explicable as due to a large diffusion of matter between the earth and sun, certainly extending as far as the earth's orbit.

FLINDERS PETRIE.

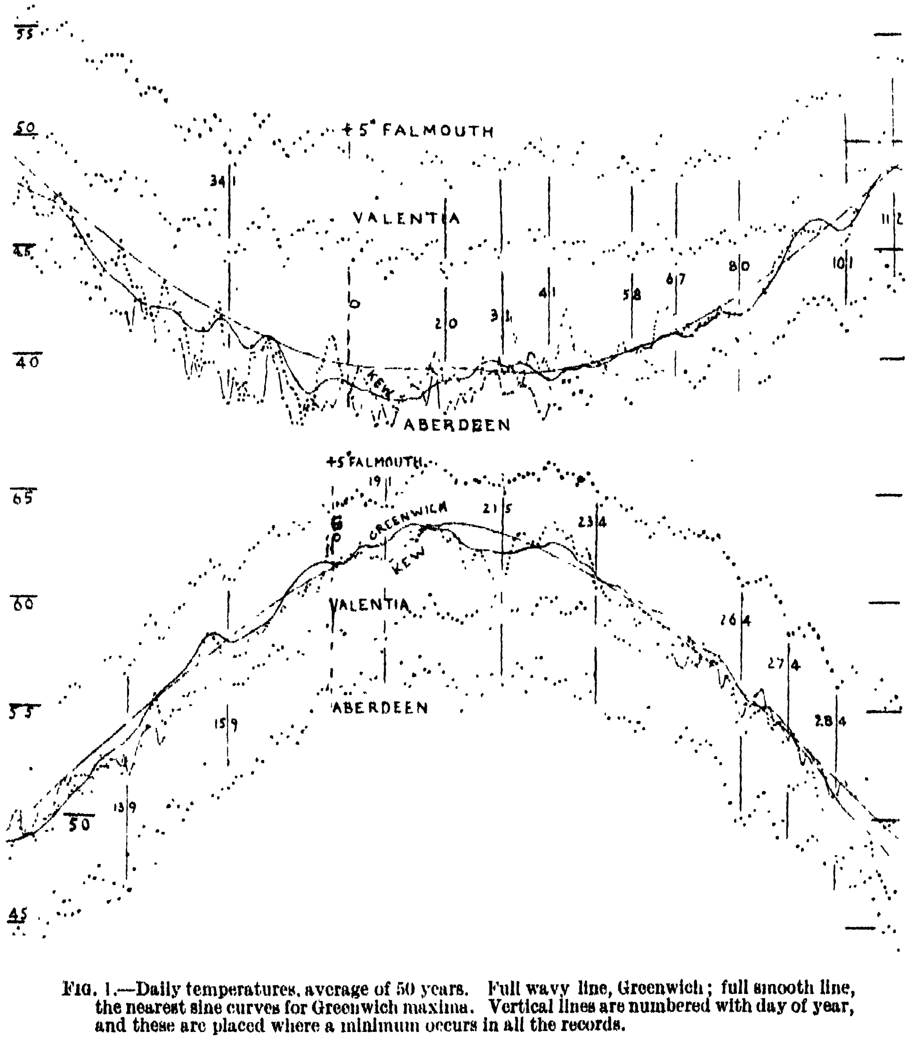

FIG. 1.—Daily temperatures, average of 50 years. Full wavy line, Greenwich; full smooth line, the nearest sine curves for Greenwich maxima. Vertical lines are numbered with day of year, and these are placed where a minimum occurs in all the records.

SIR FLINDERS PETRIE'S suggestion that regular periods of low temperature may be caused through partial cutting off of the sun's rays by cosmic dust is an old one, but is not supported by any real evidence. In Britain temperature is governed far more by wind direction and cloud amount than by solar radiation, especially in winter, when it is practically independent of latitude. The only real test of the cosmical hypothesis would be the examination of averages over a number of years of the daily measurements of solar radiation made by the Smithsonian Astrophysical Observatory. I do not think this test has yet been made; probably the number of observations is still insufficient. The occasional agreements between minima at different stations, shown on Sir Flinders Petrie's curves, may be due to the frequent occurrence of extensive systems of northerly winds on those days, or may be merely accidental coincidences.

C. E. P. BROOKS.

Bird Flotation.

IN commenting on a paper of mine in NATURE of June 14, p. 902, it is suggested that the ability of a bird to extend its feathers further from the skin may enable it to displace a greater volume of water when afloat than the volume measurable to the same surface level when ashore.

Undoubtedly this ability does exist, but, in comment upon the suggestion, I would like to point out that, if the displaced volume were materially increased in this manner the bird could not maintain an upright position but would overturn. This instability is due to the lowering of the metacentre, so that it would be brought well below the centre of gravity of the bird. The facts can be ascertained by calculation and experiment. A duck was provided with a waterproof jacket fitting closely against the underbody feathers; when put afloat, the freeboard of this bird was about one-eighth of an inch less than without the

jacket, but the bird was unable to remain upright. It lolled over about 15° to port, or to starboard, as set; and, from such data, the position of the centre of gravity could be obtained with reasonable accuracy.

As regards the suggestion that a check might be employed to measure the actual water displaced, this is not so simple a matter as it may appear. It seems necessary to define the word 'displacement' as applied to flotation.

A waxed needle can be made to float by the aid of surface tension, and, when doing so, actually displaces a volume of water more than seven times its own volume, however absurd this may seem. In a similar sense, a bird weighing 5 lb. on land may, and must, displace a volume of water weighing 5 lb. In the case of the needle, the weight of water below the line of contact of needle and water surface is only about one fourteenth of the weight of the needle; in the case of the bird, I contend that the weight of water displaced below the line of contact between bird and water surface is only about one-third of the weight of the bird. Possibly surface tension accounts for $\frac{13}{14}$ of the weight of the needle, and for $\frac{2}{3}$ of the weight of the bird. Are we sure, however, that surface tension is the supplementary force in action in the latter case? The usually observed characteristics of surface tension do not seem to be apparent.

The usual meaning of the term 'displacement', when applied to ships or other floating bodies, is restricted to the volume of the body which lies below the line of its contact with the water-surface; and in this sense it was used in the paper to which the comments referred. FRANCIS H. ALEXANDER.

Armstrong College,
Newcastle-on-Tyne, Aug. 5.

IN his original paper, Mr. Alexander, while examining curious suggestions such as that the super-inflation of the internal air-sacs might account for flotation, did not mention the possibility of, and made no allowance for, increased displacement due to the fluffing out of the feathers. Therefore his calculation regarding the amount of water displaced was invalid. His argument against the practical value of the suggestion, that it would cause instability, ignores the power of the living bird to control its balance by its peculiarly adapted feet and perhaps also by feather adjustments. Yet this is the one power that his waterproof jacket experiment demonstrated, for although he actually lowered the centre of gravity, the bird became unstable—obviously because its control had been interfered with. We still think that Mr. Alexander's data are insufficient; until he has measured the actual displacement of the swimming duck and found the water displaced to weigh less than the bird itself, it is futile to argue about supplementary forces of 'levitation' or any other force. Last week, I watched a grebe at one time swimming high in the water, at another time almost submerged. That suggests an alteration in specific gravity, that is to say, since the bird's weight is constant, in volume; and the raising or adpressing of the feathers, with a corresponding increase or decrease in the air-jacket, seems a possible and natural explanation of the change.

THE WRITER OF THE NOTE.

Crystal Structure of Normal Paraffins.

DR. MÜLLER has recently (*Proc. Roy. Soc.*, A, vol. 127, p. 417) made a detailed study of the effect of temperature on the crystal structure of the normal paraffins. He found two modifications, a 'normal' structure *A*, and a second form *B*, the *A* form having a 001 spacing 2 A. longer than the *B* form. Paraffins having more than 22 carbon atoms were found only in the 'normal' *A* form, whilst those of carbon content from 11 to 22 could assume both modifications. The 'normal' form of these was only stable at temperatures near the melting points.

We have recently examined specimens of hexacosane (26), triacontane (30), and tetratriacontane (34). They were supplied by Prof. Garner, and had been prepared by electrolysis of the pure acids, purified by distillation and crystallisation from alcohol, and finally digested with concentrated sulphuric acid at a temperature of about 130° C. Final crystallisation was from alcohol or benzene. Hexacosane and tetratriacontane showed two *stable* forms at room temperature. One had the normal *A* spacing, whilst the other spacing, about 4 A. shorter, was obviously not the *B* 'second form'. In hexacosane this *C* form occurred alone in the crystals from benzene and from alcohol, whilst a melted layer showed both *A* and *C* spacings, the former being the stronger. Crystals of tetratriacontane from benzene gave only *C* spacings, a layer evaporated rapidly from benzene had equally intense *A* and *C* lines, whilst melted specimens showed only the *A* or 'normal' form. The triacontane did not yield quite such brilliant photographs and was in the 'normal' form under all conditions. The spacing of this preparation was rather high, and we believe it to have been less pure than the other two. In no case did we obtain a spacing corresponding to Müller's *B* form.

It seems probable that pure *even* numbered hydrocarbons crystallise in the *C* form if the chain has 26 or more carbon atoms. This is in striking contrast to the odd numbered paraffins, for the single crystal of nonacosane (29) examined by Müller (*Proc. Roy. Soc.*, A, vol. 120, p. 437) had an *A* spacing and was undoubtedly of the highest purity.

This alteration of habit of the longer odd and even numbered hydrocarbons is in accord with the behaviour of similar compounds. Even numbered monobasic fatty acids of 16 or more carbon atoms have two stable crystalline forms at ordinary temperatures, whilst at similar temperatures corresponding odd acids exist in only one modification. One of us has found the same habit in the primary alcohols. In paraffins and alcohols the odd chains favour the form with the longer spacing, whilst the even molecules adopt the shorter modification. In acids this is reversed. Dr. Müller has given reasons on geometrical grounds for differences in the behaviour of odd and even chains (*Proc. Roy. Soc.*, A, 129, p. 317).

The spacings below are in agreement with Dr. Müller's values for the *A* forms, and the divergence of the *C* from the *A* values shows that if the *A* molecule is vertical to the planes the *C* chain must be inclined.

No. of Carbon Atoms.	Setting Point °C.	Spacings.	
			C
26	56·2	35·0	31·05
30	65·3	40·5	..
34	72·4	45·3	40·00

An important feature of the *C* spacings is their approximation to the *A* values of other paraffins. Tetracosane has an *A* spacing of 31 A. compared with 31·05 for the *C* form of hexacosane, whilst the *A* spacing of triacontane corresponds to the *C* of tetratriacontane. We have only found the *C* spacings in the best specimens we have examined, and believe their appearance to be a very good criterion of purity.

Raman Spectrum of Diamond.

IN the course of an examination of the infra-red and ultra-violet regions of the spectrum of a large number of diamonds, we have come across one which, unlike the others, is transparent both at about 8μ, and also in the ultra-violet so far out as $\lambda 2300$. This diamond was consequently well suited for determining the Raman effect throughout a much more extended region of the spectrum in which exciting mercury lines are available.

With this diamond we have in fact identified no less than 17 Raman lines originating from mercury lines within the range of spectrum from $\lambda 4358$ to $\lambda 2378$. The mean value of all differences is 1333 $cm.^{-1}$, a value lower than we reported in NATURE of May 10, p. 704, but agreeing with that of Ramaswamy in the same issue, and of Bhagavantam on Aug. 2, p. 168. This still corresponds to $7{\cdot}5\mu$, which is removed from the centre of the infra-red band at $8\ \mu$ found by us in most diamonds.

With a quartz spectrograph the diffuse band found faintly by Ramaswamy and by Bhagavantam is fairly strong, with its centre about $\lambda 4156$ as they report. If this diffuse line originates from $\lambda 4046{\cdot}6$, the value of $\Delta\nu$ is 651 $cm.^{-1}$ corresponding to $15{\cdot}4\mu$ about.

In NATURE of June 7, p. 855, Prof. F. Simon is inclined to identify this difference with Reinkober's band in the infra-red at 14μ, but in the examination of the infra-red spectra of a good many diamonds we have failed to detect a band there. Nor have we detected any other Raman line with this difference of frequency, although there are some places in the ultra-violet Raman spectrum where such a line might be overpowered by strong scattered unmodified mercury lines and the continuous spectrum accompanying them.

Sperms as Living Liquid Crystals.

IT is customary to draw the boundary between living organic and inorganic matter so that crystals represent the highest form of inorganic material and low organisms form the beginning of the organic world, with a definite and deep physiological gap between the two categories. In my opinion, this gap does not exist, since the sperms, which are undoubtedly living, are at the same time liquid crystals.

Stereochemically, Vorländer recognises the long straight stretched molecules as the chief principle in the building of artificial liquid crystals. The protein molecules of the sperms share with these the fine chain structure, and their nucleoproteins also, according to the most recent researches of Levene and London, possess a corresponding stereochemical type. The optical behaviour clearly demonstrates this stereochemical arrangement both in the artificial liquid crystals and in the sperms. The former are optically uniaxial and show positive or negative double refraction. The sperms have also long been recognised as optically anisotropic, and W. J. Schmidt has definitely proved that in the living seedthreads of *Sepia officinalis* L. the chromatin portion of the head exhibits double refraction of the type of an optically uniaxial crystal ($\omega = 1{\cdot}544$; $\epsilon = 1{\cdot}501$; hence $\omega - \epsilon = 0{\cdot}043$). In addition, it is important to note that the double refraction phenomena are the same both in the living sperms and in specimens which have been preserved in alcohol. Debye-Scherrer diagrams show, as well as the alcohol ring, an interference due to the sperms, which surrounds closely the spot of the primary beam, in agreement with the nature of liquid crystals. With regard to the morphological conditions, the moulding forces of surface tension together with the fine structure give rise to many corresponding forms.

University, Freiburg i/Br.

Mushrooms—Mineral Content.

SPECTROGRAPHIC analysis of mushrooms by the method described in NATURE of April 20, 1929, p. 601, has revealed a remarkable composition. A button mushroom from the Cromer district was divided into skin, white portion, gills, and stem and the parts were dried in a water oven at 100° C. The analyses prove that each part has a high potassium and a low calcium content; the skin contains lithium and it contains most iron. Phosphorus in the dried material varies from about one to three per cent, the gills containing most. The chief interest lies in the presence of silver and copper; all parts contain these, the stem containing least. The spectra of four standards, containing from 0·001 to 0·01 per cent of silver and from 0·002 to 0·02 per cent of copper, and other elements, were photographed on the same plate as the spectra of the parts of the mushroom. Comparison of the spectra proves that the skin, white, and gills contain somewhat more than 0·02 per cent of copper and that all the parts contain decidedly more than 0·01 per cent of silver; the silver content of the gills appears to be not less than 0·05 per cent.

The white portions and the gills of two other mushrooms, a button and a flat variety, from the Loddon district, 30 miles from Cromer, have been analysed with similar results.

The investigation is to be continued and extended with the assistance of Mr. H. J. Howard.

HUGH RAMAGE.

July 26.

Photography on Copper.

THE interesting observation recorded by Dr. C. J. Smithells in NATURE of July 26 is not new. During the course of a long series of experiments on 'metal colouring' at the Birmingham Technical College about thirty years ago, it was found that copper articles, which had been coloured by immersion in a hot solution of cupric chloride, blackened rapidly on exposure to light. I made a number of attempts to fix photographic prints obtained from ordinary negatives by this process, but in every case the image itself suffered from attack by the reagents used.

The most satisfactory method of preparing the sensitive plates was found to be as follows. A sheet of brass or copper was first coated thinly with copper electrolytically and then it was immersed for a few seconds in a boiling solution of cupric chloride, or in a copper sulphate solution containing a little common salt. If the surface after this treatment was not perfectly uniform in appearance, the sheet was scratch-brushed and immersed again in the hot solution. It can then be washed and dried with a cloth. The coating is salmon-pink in colour, is perfectly adherent, and shows none of the white film mentioned by Dr. Smithells.

Distribution of some Oceanic Birds in the Waters East of New Zealand.

By Dr. P. Jespersen, Copenhagen.

THE Danish Research Ship *Dana*, sent out for a two years' expedition around the world by the Carlsberg Foundation in Copenhagen, under the leadership of Prof. Johs. Schmidt, director of the Carlsberg Laboratory, spent the months of December 1928 and January 1929 in New Zealand waters. From Jan. 2 to Jan. 13 investigations were carried out in the waters east of New Zealand on a cruise, going out from Auckland in a southerly direction to a position situated about 49° S. Lat. and 177° E. Long., from there going west to about 172° E. Long. and farther north along the east coast of the South Island to Wellington.

On the whole circumnavigating expedition of the *Dana*, observations of the bird-life were made on the high sea, but as we on the above-mentioned cruise in New Zealand waters had the New Zealand zoologist, Mr. R. A. Falla, a keen and clever ornithologist, on board the *Dana* as guest, the ornithological observations on this cruise were made with a higher degree of accuracy than in ordinary circumstances. In very few areas of the world are the birds belonging to the order Tubinares represented by so many different species as in the New Zealand waters, and as Mr. Falla has especially studied these birds, it is first of all due to Mr. Falla's knowledge about these oceanic birds that the ornithological observations were so extensive on this particular cruise.

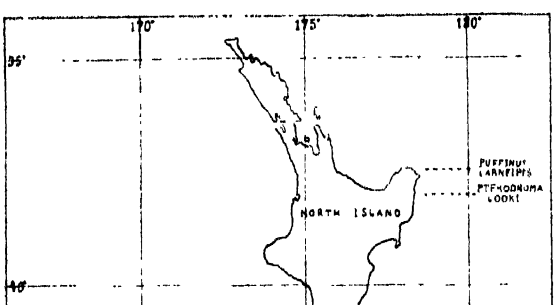

Fig. 1.—Map showing the southern limit for northern breeding species of birds.

Our most important task was to determine, so far as possible, the limits for the distribution of the various species of birds in the open sea, and in the following a brief account of the result of our investigations will be given, especially in regard to the distribution of the various species from north to south. It must, however, be remembered that the results apply only to the month of January,

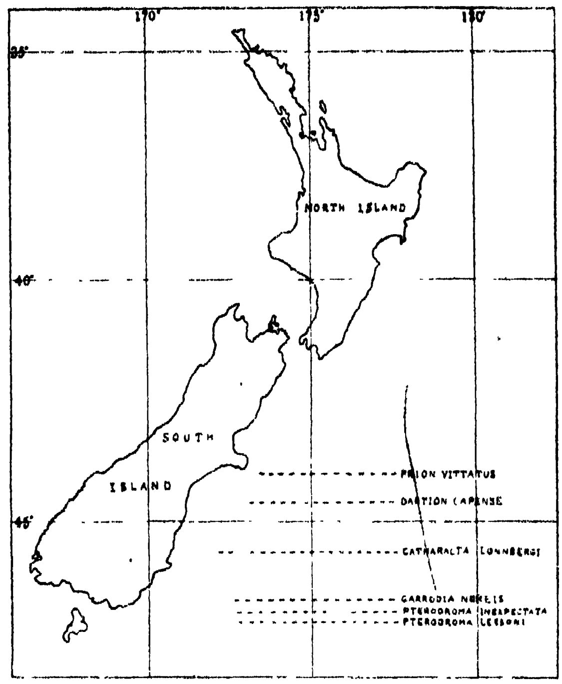

Fig. 2.—Map showing the northern limit for southern breeding species of birds.

which is the height of the breeding season, and that the position of suitable breeding islands must have some influence on distribution at this time.

The observed species will be divided into two groups, namely, the northern breeding species and the southern breeding species. To the first-named group belong birds breeding on the north island of New Zealand and the small islets lying north of this, and the last-named group comprises species breeding on the south island of New Zealand or on islands in more southern latitudes.

We will first consider the distribution of the northern breeding species, and the chart, Fig. 1, shows approximately the southern limit for the occurrence of these birds in the open sea.* North of the lines indicated the different species are seen more or less frequently, while these species are not observed south of the respective lines. It will be seen that the two species, the pale-footed Shearwater (*Puffinus carneipes*) and Cook's Petrel (*Pterodroma cooki*), both of which were observed in large numbers in the waters round the north coast of the north island, already ceased to appear when we passed off the East Cape (about 38° S.). Both species are also only known to breed on islets north of this point. Other northern breeding species extend their distribution more to the south. In Cook Strait we thus found the southern limit

* In regard to the systematic names I refer to "Birds of the Ocean" by W. B. Alexander (G. P. Putnam's Sons, New York and London, 1928), a book which has given me the most valuable assistance in my ornithological observations during this cruise with the *Dana*.

for the appearance of the white-faced Storm-Petrel (*Pelagodroma marina*), but in regard to this species it must be mentioned that its breeding area is not restricted only to the north island of New Zealand, as it is also noted as breeding on Chatham Island and Auckland Island (*cf.* W. B. Alexander, p. 92). The southern limit shown, therefore, apparently only accounts for the New Zealand breeding specimens of this species. A little more to the south (about 42° S.) we find the most southern occurrence of the great-winged Petrel (*Pterodroma macroptera*), and the grey-backed Shearwater (*Puffinus bulleri*) is observed so far south as off Banks Peninsula (about 44° S.). Both the two last-named species are in these regions only found breeding on the north island of New Zealand and surrounding islets.

As we gradually came more to the south we met several species of birds at sea, which we had not observed before, and all these species were breeding on the south island of New Zealand or in more southern latitudes. The northern limit of the southern breeding species in this month of the year was found about 44° S., as will be seen on Fig. 2.

Off Banks Peninsula we thus met the first specimen of the broad-billed Prion (*Prion vittatus*), which is recorded as breeding on Stewart Island and Chatham Island, but elsewhere on islands under more southern latitudes. A little more to the south we fixed the northern limit for the Pintado Petrel or ' Cape Pigeon ' (*Daption capense*), as this species is commonly called by sailors. The nearest known breeding-place for this species is Antarctica, although it probably occurs at the Snares and other sub-antarctic islands. About 45°-46° S. Lat. the first specimen of the dark Skua (*Catharacta lönnbergi*) was observed. This species, which is recorded as breeding on the south island of New Zealand, appeared always singly. In the most southern part of the area investigated —between 46° and 47° S. Lat.—we further noted other species, which are only known breeding on South Island or in the sub-antarctic islands of New Zealand. These were the following: the grey-backed Storm-Petrel (*Garrodia nereis*), Peale's Petrel (*Pterodroma inexpectata*), and the white-headed Petrel (*Pterodroma lessoni*), all of which only appeared as single specimens. In most cases the largest numbers of birds were observed during the morning and the forenoon, and nearly all were flying in an easterly direction, presumably indicating that it was breeding birds making seaward from land.

In connexion with the recorded observations of oceanic birds it is of interest to look at the surface temperatures in the waters east of New Zealand, as found during our trip in the month of January 1929.

It will be seen from the chart (Fig. 3) that the surface temperature is decreasing in a rather high degree from north to south, namely, in the investigated area, from more than 19° to less than 13° C. It is the cold antarctic water, which here advances along the east coast of New Zealand. The isotherms are based on rather few observations and only on this single cruise, but they seem to indicate that the temperature especially is quickly decreasing from 17° to 14° C. This is the case between 42° and 44° south latitude, and it is just in this area that we found in most cases the southern limit for the northern breeding species and the northern limit for the southern breeding species of sea-birds. The marine biological investigations on board the *Dana* along the east coast of New Zealand also demonstrated a very great difference in the composition and kind of plankton on the way from north to south. Thus we found

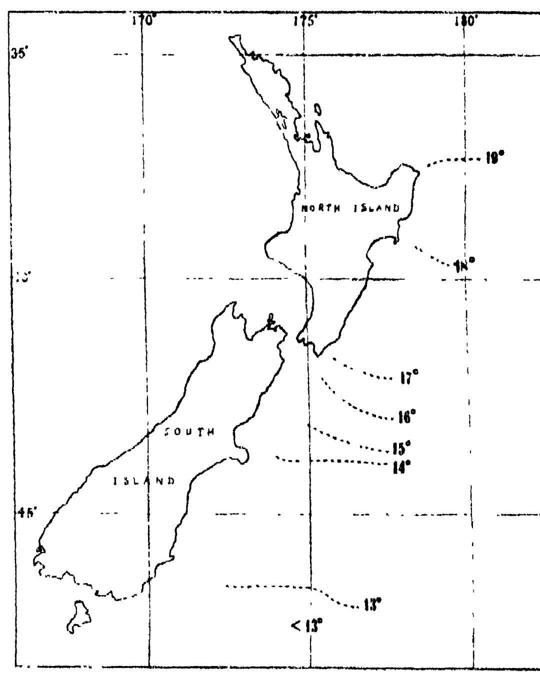

FIG. 3.—Map showing the surface temperatures in the waters east of New Zealand on the cruise of the Danish Research Ship *Dana*, Jan. 2-13, 1929.

the plankton more and more characteristic of the colder water when we were going south, and on the most southerly stations the plankton had in many ways certain resemblances to that in the waters round Iceland and the Faroe Islands in the North Atlantic. Due to the different temperatures in the water the food for the birds living over the high sea thus will be different in the various latitudes, and therefore the surface temperature of the water, in an indirect way anyhow, is a factor of great importance in regard to the distribution of various sea-birds in these waters.

From the above-mentioned observations it will be understood that the composition of the bird-life is quite different in the northern and in the southern parts of the investigated area, but for certain species of sea-birds it has not been possible within this area to determine limits for their distribution. Two species of Albatross (*Diomedea exulans* and *Thalassarche melanophrys*) and the Giant Petrel (*Macronectes giganteus*)—the nearest breeding-places for these are presumably the sub-antarctic islands south of New Zealand—we thus met a little north of New Zealand and within the whole investigated area, and the Fluttering Shearwater (*Puffinus gavia*)

which is found breeding both on North and South Island and on the Snares south of New Zealand was recorded rather near land along the coast of both the north and the south island. Furthermore, it may be mentioned that the Sooty Shearwater (*Puffinus griseus*), which is known to breed on both the New Zealand islands, on the south-going trip was seen about 44° south latitude, but during the following part of the route, as well as in Cook Strait, the species was observed daily and sometimes in large numbers.

To complete the list of more oceanic birds which were observed and determined with certainty during this cruise, it may be mentioned that several specimens of the Fairy Prion (*Pachyptila turtur*) and the Little Penguin (*Eudyptula minor*) were observed during the passage through the Hauraki Gulf as well as in Cook Strait.

Competition between Plants.*

THE recent publication of the work of Clements, Weaver, and Hanson, on "Plant Competition" reports the results of numerous experiments designed to analyse the competitive functions in plant communities. Many of these consisted of transplantations of species characteristic of one phase of a succession into a type of vegetation representing an earlier or later phase. In view of the fact that the major mortality amongst plants would appear to be in the juvenile stage of development (cf. NATURE, May 31, p. 817), conclusions based upon transplantations of established plants must obviously be accepted with considerable reservation when evaluating the competitive relations between species, but recognising these limitations such have considerable value.

In a recent address (*Journal of Ecology*, August 1929) the reviewer, dealing with the biological equipment of species in relation to competition, emphasised the importance as factors in the competition struggle of such features, *inter alia*, as potential height, rate of growth and spread, development of the root system, capacity for reproduction, and the mode and percentage of germination. The experiments of Prof. Clements and his collaborators furnish additional corroboration of these conclusions. They state that practically all the advantages or weapons of species are epitomised in the two words amount and rate. In competition between short and tall grasses the latter were successful under moist conditions, but under dry conditions or when the herbage was grazed the shorter grasses, as might be expected, more than held their own. *Sporobolus asper* was successful in competition with *Andropogon furcatus*, despite its shorter stature, a result attributed to its more efficient root system. *Elymus canadensis* is the victor in the struggle with *Panicum virgatum* owing probably to the earlier and more rapid growth of the former.

The importance of percentage germination was shown by cultures of *Andropogon glaucum* with *Andropogon scoparius*, in which it was found that either species became the dominant when the number of its seedlings had been considerably in excess of those of the other. The advantage of priority of occupation was shown by transplantation experiments, in which it was found that the species already established were almost always victorious over those introduced—a conclusion which supports the contention that mass migration rather than random inoculation is the important factor for successful establishment.

Experiments upon the competition between forest and prairie show the importance of moisture in favouring the arboreal vegetation. The transition zone between the grassland and forest is a broad one of fluctuating extent, and the hypothesis is put forward that the advance or retreat of the forest margin respectively corresponds to the wet and dry climatic phases which coincide with the sunspot cycle.

The observations of Cockayne in New Zealand, and of other experienced field botanists, have emphasised the absence of naturalised species from virgin climax communities in regions where disturbed vegetation has become invaded by an extensive alien flora. Denudation experiments also bear witness to the importance of priority of occupation in the plant world. Cornfields which have passed out of cultivation may still show remains of the weed flora thirty-five years after they have ceased to be arable land, whilst wood-anemones and other members of the shade-flora will persist long after a woodland area has been converted into pasture. Such persistence is indicative of the comparative stability of plant communities and shows that the pressure of competition may operate over a considerable period before its effects are manifest. For this reason the drastic changes involved in many competition experiments, such as those here considered, which operate within a brief period of but a few years at most, are probably not directly comparable to the competitive processes of Nature, which if sure in their outcome are often extremely slow in their manifestation. Nevertheless, the amount of experimental work bearing on the phenomenon of competition is so meagre that we welcome the publication of any such studies whilst recognising the caution necessary in applying conclusions based on these artificial conditions to the explanation of competition phenomena as they occur in Nature.

The work is more of a very detailed account of the experiments than, as might be inferred from the title, a general résumé of the subject, and indeed one is conscious of a sense of inadequacy due, in part, to a lack of coherence in the method of presentation and, in part, to the omission of data necessary to the proper appreciation by the reader of the real significance of these experiments.

E. J. SALISBURY.

* Plant Competition: An Analysis of Community Functions, by F. E. Clements, J. E. Weaver, and H. C. Hanson. Pp. xvi + 340, with 32 Plates, 30 Figs., and 133 Tables. (Washington, D.C.: Carnegie Institution, 1929.)

Some Scientific Instrument Makers of the 18th Century.*

By ROBERT S. WHIPPLE.

ADAMS appears to have given a great deal of consideration to the method of measuring magnification of microscopes, and illustrates in detail in the "Micrographia Illustrata" (Plate 14), fourth edition, various micrometers for this purpose, amongst others the micrometer he made in 1761 for the silver microscope of George III. This instrument originally formed part of the King's collection and is now in the Lewis Evans collection. It has been described by Messrs. Clay and Court at some length.[1] Although the details of workmanship in this instrument are excellent, the instrument as a whole must be regarded as an ornament rather than a serious contribution to microscopy. Such is not the case with the earlier instrument made for the King when Prince of Wales, and known as the "Prince of Wales" microscope (see Fig. 2). It is particularly interesting as embodying the method of mounting a microscope on trunnions; perhaps, as Clay and Court remark, the first microscope so supported. There are three stages, one of which (shown in the bottom of the illustration) is of great interest, having micrometers registering in two directions at right angles. The screws have 100 threads to the inch, and the scales on the heads are divided into 100 parts, so that the micrometers read to 1/10,000 inch. The stage shown in position on the microscope was intended to carry a frog for demonstrations of the circulation of the blood. It is a matter of general knowledge that King George III. was keenly interested in scientific matters, and wished that his family should be instructed in science. Dr. Demainbray commenced to teach the Royal family in 1754, and appears to have used for this purpose the apparatus which formed the major part of what is known as the King George III. collection. The instruments in the collection were catalogued in a manuscript book which is still preserved in the Kew Observatory, and also in a catalogue which is now in the Science Museum at South Kensington. The instruments were housed at the Kew Observatory until 1841, when they were transferred to King's College, London. In 1925 they were removed to the Science Museum at South Kensington, where the majority of them can be studied. The story of the collection was told in some detail in a paper before the Optical Convention of 1926.[2] The majority of the instruments intended for instructional purposes were made by George Adams, although few of them bear his name. Fortunately two books of instructions have been preserved, and it is by means of these that it is possible to state that the majority of the instruments were made by Adams.†

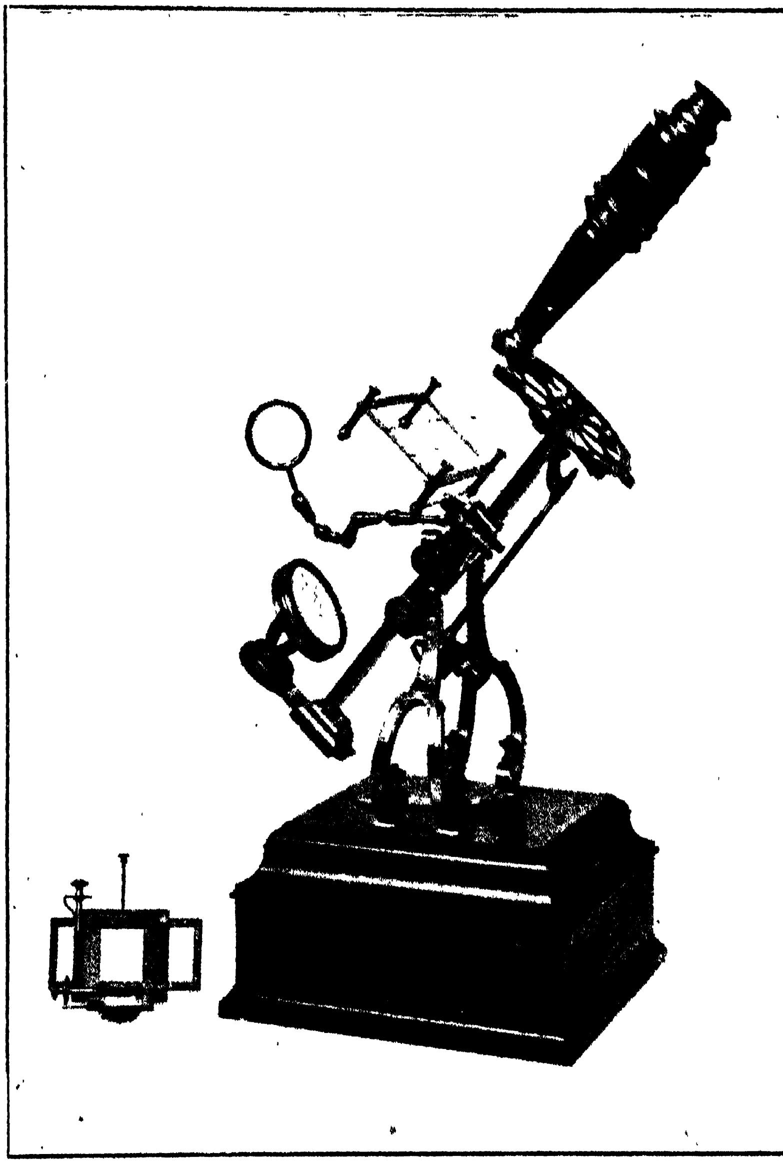

FIG. 2. —Microscope by Adams, generally known as the "Prince of Wales" microscope.

The instructions consist of two manuscript books about 19 in. × 13 in., with two small books about 12 in. × 9 in. The pages of the latter are of blue paper, on which are pasted white sheets on which the illustrations have been drawn. One book is entitled :

* Continued from p. 246.

† It is by the courtesy of the Delegacy of King's College and the Director of the Science Museum that I have been able to examine these books.

"A Description of an Apparatus for explaining the Principles of Mechanicks made for His Majesty King George the Third by George Adams, Mathematical Instrument Maker to His Majesty. In Fleet Street, London, 1762." The second book is entitled: "A Description of the Pneumatic Apparatus made by George Adams in Fleet Street, London, 1761." In the case of the "Mechanicks" the final sheets of drawings were in course of preparation, the outlines having been drawn, but the shading is incomplete and reference figures have not been inserted. It was evidently intended that the sheets of drawings should be bound as a book to accompany the instructions, and probably that the latter should be bound also when the drawings were completed, but these were never finished. In the case of the "Pneumatics", drawings on plates the same size as the manuscript (19 in. × 13 in.) were in course of preparation, and those that are finished are excellently drawn. In the case of both books it was no doubt intended to have the manuscripts bound—as they are now a series of loose leaves in rough covers—but this was never done. The two books containing the comparatively rough drawings appear to have been the centre around which Adams built up the experimental courses. In the case of the "Mechanicks" a little mathematical work is also included, although the course is essentially experimental and based on Desagulier's translation of the classical work of 's Gravesande, the distinguished professor of mathematics at Leyden.[3]

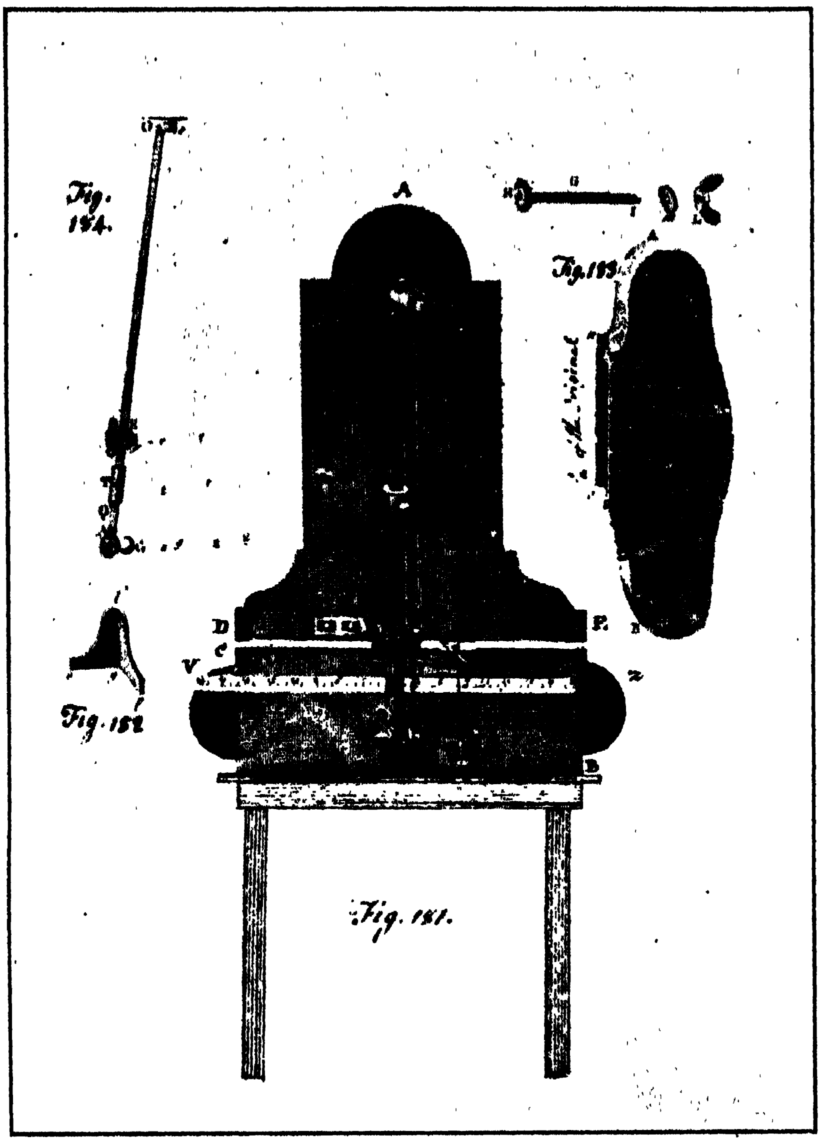

FIG. 3.—'s Gravesande table for pendulum experiments, as modified by Adams.

Adams apparently cut out many of the illustrations from Desaguliers' book, and added pencil or ink modifications to guide the workman. Fig. 3 is an example of a modification of this kind. The apparatus is intended to demonstrate experiments on pendulums and the impact of bodies; it is generally known as "'s Gravesande table". The central illustration in Plate 25 of Desaguliers' book has been cut out and modified. The additions are shown by the cross hatching, but the parts removed have been carefully cut away before mounting. The finished instrument can be seen at South Kensington, and comparing the original design with that made by Adams, one has to admit that the latter is more graceful than the original. The workmanship of the whole of this piece of apparatus is excellent. Adams evidently considered the cost of making apparatus, because several modifications are introduced with the view of reducing labour. The drawing of a table is shortened in pencil, with the words "Too long" written against it, and there are small pencil sketches at the side showing alterations. A ring is made to take the place of a fairly elaborate handle, and a simple glass basin is used instead of a brass bowl.

There can, I think, be little doubt that, judging from the large number of sketches that are dimensional, they must have formed the actual drawings from which the apparatus was built. Not improbably the workman had made some of the instruments previously for other customers, so that he did not require detailed drawings. The work of making the instruments may have spread over a few years. In the case of one of the pneumatic instruments mention is made of apparatus previously supplied and now "in one of the Cabinets of the Palace at Richmond".

All through both books references are made to various scientific authors; for example, when discussing the Archimedian screw five references are given.

One of the most interesting instruments shown in detail is the rotating speculum suggested by Searson as an artificial horizon. Full details of the construction are given, and a manuscript copy of Emmerson's paper in the *Philosophical Transactions*, vol. 47, p. 352, is included with the manuscript papers of the collection. Adams commences the description of the instrument with a short introduction :

"I received this invention from the late Sir Jacob Ackworth, first Commissioner of his late Majesties Royal Navy ; soon after the inventor Mr. Searson was unfortunately lost on board His Majesties Ship the 'Victory'."

Adams's mechanical ability shows itself in his instructions as to lubrication :—"It is necessary to put a drop of sweet Oil into the concave Steel polished segment of a sphere, for if the speculum be whirled without Oil it does not spin much above ten or twelve minutes, with Oil it will spin generally 36 minutes."

Only two of the illustrations are actually signed by Adams, although there is little doubt that the various notes are in his writing. There is a short four-page manuscript slipped into one of the books, which is a sheet of instructions with regard to some details of an instrument. Adams presumably wrote his notes out in this manner, and they were afterwards transcribed in the elaborate copy-book writing of the instructions.

The fourth edition of the "Micrographia Illustrata" is dated 1771, and Adams died in 1773. He must have lived a full life, as, judging by the large number of instruments that may be found bearing his name, and by the "Catalogue of Mathematical, Philosophical and Optical Instruments" published in the end of the "Micrographia Illustrata", he must have had a large and flourishing business. Adams left it to a son—George (born in 1750)—who added greatly to the prestige of the firm. He was a cultured man, and a favourite at Court. He wrote a large number of books, the majority of which passed through more than one edition. The most famous of his books was his "Essays on the Microscope" published in 1787. In the preface he states frankly that he had intended to confine himself to a republication of his father's work the "Micrographia Illustrata", but that knowledge of the subject had increased so much since his father wrote that he felt the book had to be rewritten. Discussing the natural history side of the subject, he states that he has endeavoured to correct some of the faults in arrangement, etc., "by arranging the subjects in systematic order, and by introducing the microscopic reader to the system of Linnæus, as far as it relates to insects". Chapter i. is an extremely interesting history of the microscope, as observed by one who lived close to many of the inventions. In it he mentions that he invented an improved form of the lucernal microscope in 1774. In Chapter iii. he mentions that "this microscope was originally thought of, and in fact executed by my father ; I have, however, so improved and altered it, both in construction and form, as to render it altogether a different instrument". He also mentions that "the great demand I have had for them, has fully repaid my pains and expences [*sic*] in bringing it to its present state of perfection". The lucernal was a simple compact form of projection microscope which met with general approval as an instrument which could be conveniently demonstrated to a number of people at the same time.

A second and enlarged edition of the "Micrographia Illustrata" appeared in 1798, edited with great care by F. Kanmacher. This editor in a footnote dwells on the fact that Adams had not given full credit to Benjamin Martin for what he had done to develop the microscope. Adams's "Geometrical and Graphical Essays", first published in 1790, was an extremely useful text-book for surveyors, civilian and military. The lectures on "Natural & Experimental Philosophy" first published in 1794, in five volumes, very nearly cover the range of physics as then understood—or in the words of the sub-title "describing in a familiar and easy manner the principal phenomena of nature and showing that they all co-operate in displaying the goodness, wisdom and power of God". One is much impressed with the immense amount of work involved in the preparation of these books, for they are all full of individuality. The lectures were evidently written under difficulties. In the preface the author mentions: "During the composition of these Lectures I have had to attend to the grateful calls of daily business, and have struggled with much weakness and langour". He passed away on August 14, 1795. We learn from an editorial note to the second edition of the "Essays on the Microscope" that Adams at the time of his death was preparing a new edition and that he had other books in view. After his death his books and instruments were sold by auction, and the stock and copyright of his books were purchased by the brothers W. and S. Jones. William Jones was responsible for the editorial work and the republishing of several editions of Adams's books. The firm also continued to make instruments to the Adams's design for many years.

The manuscripts and plates of Adams the elder were inherited by his widow, who gave them to her younger son Dudley. He edited a thirtieth edition of the treatise on the globes, published in 1810. It is said that he had intended to publish another edition of the "Micrographia Illustrata", but it is not improbable that the revised edition (1798) of his brother's "Essays on the Microscope" rendered this unnecessary. Dudley Adams appears to have continued in the instrument business, as Mr. Court possesses a statement written on the back of a shop print, about 1800, of the wholesale trade terms for telescopes. These were evidently of the short brass draw-tube type which Dudley Adams had developed. The note attached to the price-list states that "the object glasses not being single but achromatic" shows that non-achromatic glasses were sometimes sold.

Time has only allowed me to dwell in detail on

four instrument makers in this century so full of scientific development. Their names are not so well known to the general public as those of Dolland, Herschel, and Ramsden. Nevertheless, the men whose work I have briefly described did an immense amount to popularise science, and to raise the standard of scientific instrument craftsmanship. How world-wide this reputation for good work became is best seen by the number of instruments of English eighteenth century workmanship treasured in the Continental museums.

James 's Gravesande, LL.D., Professor of Mathematicks at Leyden and F.R.S. Translated into English by the late J. T. Desaguliers, LL.D., F.R.S., and Published by his son J. T. Desaguliers. Sixth Edition 1747.

Obituary.

MR. A. E. SEATON.

THE death of Mr. Albert Edward Seaton, which occurred at Hemel Hempstead on Aug. 8, robs British shipbuilding and marine engineering circles of one of its oldest and best known representatives. For nearly half a century Seaton's "Manual of Marine Engineering"—now in its twentieth edition—has been familiar to marine engineers, while his "Pocket Book," compiled in collaboration with Mr. H. M. Rounthwaite, is to be found in every drawing office. His "Manual" would alone cause his name to be remembered, but he had an almost lifelong association with the Institution of Naval Architects, and during the course of his long career enjoyed the friendship of many of the most distinguished members of his profession.

Born at Padstow, Cornwall, in 1848, Seaton entered Devonport Dockyard in 1864 as an engineer student with the object of following a naval career, and four years later, as a result of his success in a severe competitive examination, he gained a scholarship to the once well known Royal School of Naval Architecture and Marine Engineering at South Kensington, which had been established by the Admiralty in 1864. During its existence of nine years, the School occupied a unique position in Great Britain, and from it came not only future chief constructors and engineers-in-chief of the Navy, but also men who rose to important positions in private firms. In Seaton's time, Woolley, Merrifield, Cotterill, and Unwin were members of the staff; the occasional lecturers included Airy, Froude, Rankine, and Scott Russell, while among the students were Elgar, White, Watts, Biles, Sennett, Durston, Pratten, Corner, and others, whose important work during the last decades of the nineteenth century and the first of this century were of the greatest value to the country in building up our great naval and mercantile fleets.

Passing out in 1872, Seaton immediately left the public service and became technical secretary to Reed (afterwards Sir Edward Reed), who in 1870 at the age of forty had resigned his position as Chief Constructor at the Admiralty. Through Reed, Seaton became associated with Earle's Shipbuilding and Engineering Co., Hull, and during the next twenty-nine years was responsible for the design and construction of not only the machinery of many vessels but also of the ships themselves.

Leaving Hull in 1901, Seaton set up in Westminster as a consulting engineer, and in 1905 succeeded his former fellow-student and lifelong friend, Alfred Morcom, as chairman of the well-known Birmingham engineering firm, Messrs. Belliss and Morcom. But much of Seaton's best work was done in connexion with the Institution of Naval Architects and other societies. He was elected a member of Council of the Institution in 1888, a vice-president in 1919, and represented it on various important committees. His knowledge of the progress of marine engineering design was probably unique, and for some years he was chairman of the British Marine Engineering Design and Construction Committee. He also took part in public life, served as a County Councillor for Hertfordshire, and was made a Justice of the Peace. His funeral took place on Aug. 12, at St. Marylebone Cemetery, East Finchley.

THE issue of the *Physikalische Zeitschrift* for June 1 contains a short account by Prof. F. A. Schulze of the work of Prof. Wilhelm Feussner, who died in 1928 at the advanced age of eighty-five years. He was born in Hanau in 1843, and studied at Heidelberg under Kirchhoff and at Marburg under Gerling. He took his doctor's degree in 1867 and became lecturer, in 1880 additional professor, and in 1908 honorary professor of theoretical physics at Marburg. He retired in 1918, but still kept in touch with modern research, and contributed to the section on interference in the new "Handbuch der physikalischen Optik".

WE regret to announce the following deaths:

Prof. A. R. Crook, for many years chief of the Illinois State Museum at Springfield, Illinois, known for his work on Cretaceous fossil fishes and geology generally, on May 30, aged sixty-five years.

Dr. J. Walter Fewkes, fellow of the U.S. National Academy of Sciences, who was chief of the Bureau of American Ethnology from 1918 until his retirement in 1928, on May 31, aged seventy-nine years.

Dr. W. S. Franklin, who retired last year from the professorship of physics and electrical engineering at the Massachusetts Institute of Technology, vice-president (Section B) of the American Association for the Advancement of Science in 1902, on June 6, aged sixty-six years.

Capt. J. T. Ainslie Walker, widely known by his work on disinfectants, who was associated with the late Dr. Samuel Rideal in perfecting the Rideal-Walker test for potency, on July 27.

Sir William Walker, C.B.E., late Director of Health and Safety in Mines Department, Board of Trade, and formerly Chief Inspector of Mines at Home Office, on Aug. 17, aged sixty-six years.

News and Views.

THE voyage of the *R100* from Cardington to Montreal and back is a definite popular success. On the technical side, a large amount of invaluable information must have been obtained from both design and operational points of view. The efficacy of the mooring mast in particular is the satisfactory reward of original ideas well worked out. The previous failure of the tail fairing, the stripping of fabric, and the dislodgment of a fuel tank seem trivial in themselves; only those in possession of all the facts can judge whether they are minor mishaps with no serious implication or symptoms of a graver nature. The framework has resisted considerable buffeting, and here again, information should be yielded as to whether the structure has an effective margin of safety or has been stressed to an excessive degree. It is clear that the best meteorological service cannot enable an airship to avoid all stress of weather during the speediest passage across the Atlantic.

ON the more general question of a regular airship service, it can scarcely be held by the most optimistic that much has been added to the stock of knowledge by the recent voyage of *R100*. Referring to the analysis of Zeppelin figures given in NATURE of Oct. 11, 1924, p. 548, it is seen that their expectation of life falls far short of eighteen voyages in eighteen months. It is by no means clear that the great increase in size of *R100* and *R101*, and the further increase now proposed, will diminish these risks, and a cautious experimental programme seems a more reasonable policy than any hasty endeavour to make good the claims of the airship's partisans. The projected flight of the *R101* to India will bring further knowledge, and those who are most critical will join in congratulating the courageous exponents of airship construction on their great technical efforts to overcome the inherent defects of size and fragility.

THE Anglican bishops, recently assembled at Lambeth, have embodied the results of their deliberations in an Encyclical Letter, and in a number of Resolutions. These appear to be inspired predominantly by a rational and enlightened spirit, and students of science will read large portions of them with interest and sympathy. Very noteworthy are the sections which deal with the relations of Christian doctrine with modern scientific and philosophic theories, which are said to provide "a climate more favourable to faith in God than has existed for generations". "New interpretations of the cosmic process are before us which are congruous with Christian Theism. The great scientific movement of the nineteenth century had the appearance, at least, of hostility to religion. But now, from within that movement and under its impulse, views of the universal process are being formed which point to a spiritual interpretation. We are now able, by the help of the various departmental sciences, to trace in outline a continuous process of creative development in which at every stage we can find the Divine presence and power. Thus scientific thinking and discovery seem to be giving us back the sense of reverence and awe before the sublimity of a Creator Who is, not only the cause and ground of the universe, but always and everywhere active within it." The Encyclical goes on to declare that "we must school ourselves to include in our habits of thought about the Creator God as much as we can of the beauty and order of the world, and of everything in life that evokes the awe, the loyalty, and the self-sacrifice of men and women at their best".

IT is all to the good that the bishops should express themselves in this way, but, as everyone knows, it is the rank and file of the clergy whose conversion to a more modern outlook must be achieved if the ideals of the Encyclical are to be fulfilled. The ordinary Christian teacher, who expounds his message Sunday by Sunday from the pulpit, must be encouraged to think out his position afresh, and to impart to others the convictions to which his studies and reflections have led him. When we remember that the average age of the Anglican clergy has been authoritatively stated to be fifty-five years, we shall realise the difficulty of the situation. The hope would appear to lie with the younger clergy. "We especially desire to impress upon the younger clergy that the Church requires the service of men who will devote themselves to the study of theology in all its branches. The Church needs learning, as well as spiritual power and practical ability in its clergy." But it should be remembered that men will not think well unless they are allowed to think with freedom. Will the young theological student enjoy the same latitude as the young scientific student? Do the bishops really mean business? In view of the importance of giving an adequate education to candidates for ordination, it is encouraging to note that the bishops express a strong preference for university training as against that given in the seclusion of a seminary. "It is essential that Christian theology should be studied and taught in universities in contact with philosophy, science, and criticism." If the gap should widen between the Church and those standards of intellectual integrity recognised in universities, it would soon cease to play any effective part in English life.

THE opportunity of the meeting at Cambridge of the fifth International Botanical Congress was utilised for the unveiling of a tablet to the Hookers in the church at Halesworth, Suffolk, on Sunday, Aug. 17, to which reference was made last week (p. 249). The inscription explains the circumstances it was desired to record; it is as follows: "This Tablet records the connection with Halesworth of the botanists, Sir William and Sir Joseph Hooker, father and son, who became in succession directors of the Royal Botanic Gardens, Kew. Sir William lived here 1809–1820, and here Sir Joseph was born 1817. Erected 1930." The tablet (of stone) is the work of the sculptor, Mr. A. H. Gerrard, of the Slade School, and is beautifully executed. The dedication service, arranged by the Bishop of St. Edmundsbury and

Ipswich, and by the Rev. H. C. Newbery, rector of Halesworth, was fully choral. The actual unveiling was performed by Sir David Prain, a successor to the Hookers at Kew, and the bishop delivered an address.

A large party came over from Cambridge, and together with other botanists and naturalists from East Anglia, about a hundred visitors were entertained to tea after the ceremony at Halesworth Church. Two members of the Hooker family were present, Mr. Reginald Hooker and Mr. Richard Hooker; the old home of the Hookers (the Brewery House) was shown by the courtesy of Miss Parry, the present owner. The visitors, who came from many countries, were delighted with the charm of Halesworth and its welcome, and with the beauty and admirable rendering of a well-designed service. It was generally felt that the tribute paid to these former citizens of Halesworth, in which so many participated, was entirely fitting. The arrangements for the execution and erection of the tablet were made by a small committee under the chairmanship of Viscount Ullswater, whilst the funds required were contributed partly by individual botanists and others contemporary with Sir Joseph Hooker, and by representative institutions, including the Royal Society, the Linnean Society, the Norfolk and Norwich Naturalists' Society, the Royal Horticultural Society, the Court of the University of Glasgow, the *Annals of Botany*, the staff of the Royal Botanic Gardens, Kew, and of the Department of Botany, British Museum, and the Ipswich Naturalists' Field Club.

America dallies with the thought of its own antiquity. While the Boston Society of Natural History has celebrated its centenary by the publication of impressive "Milestones", reviewed by Prof. Stanley Gardiner in our issue of Aug. 9, p. 195, the Philosophical Society of Washington commemorated more modestly its thousandth meeting on Jan. 18 last. The foundation of the Society was due in some measure to the Civil War, for it was the recurrence of normal times, after a disturbance which had disorganised the meetings of scientific men in the capital, that led to the setting up of a formal organisation at the regular meetings of which all the sciences, save those of speculative thought, might play a part. Previous to the foundation of the Philosophical Society on Mar. 13, 1871, the capital had been served from 1810 onwards by a series of agricultural, medical, and botanical societies, and finally by the National Institute, which was disbanded near the beginning of the Civil War. The Philosophical Society has seen many changes, from the time in 1874 when it was minuted that its members should appear in the records under no title other than plain "Mr.", and when formality of debate, associated with full evening dress, was the rule, but it has throughout been supported by a noble band of 'intellectual giants' and has made many contributions to the progress of science, reaching far beyond the confines of its meeting room. Since 1911 its *Bulletin* has ceased publication, and it has supported and published in the *Journal of the Washington Academy of Sciences*.

In the Italian National Park of Gran Paradiso the numbers of wild goats and of chamois have increased beyond reasonable limit, the former being reckoned to number 2800-2900, the latter 1600-1800. Accordingly the Royal Commission which controls the Park has decided that during the coming autumn permits will be granted to hunters, for a consideration, to shoot these animals. The licence is stated by the Italian sporting journal, *La Caccia e la Pesca* of June 15, to cost 10,000 lire for each goat the sportsman desires to shoot, and 600 lire for each chamois, and accredited hunters will be accompanied by a warden. In order to ensure the continuance of healthy stock upon the mountains, a breeding enclosure for goats is to be constructed in the Valsavaranche, whence young goats will be distributed, and Bardonecchia deer and mouflon from Sardinia are to be transported to suitable localities so that, so far as possible, the typical fauna of the Park may be restored.

That considerable progress has been made at the Rubber Research Institute of Malaya is evident from the annual report for 1929, increased co-operation between the Institute and other cognate institutions in Malaya, Great Britain, and elsewhere being worthy of special mention. Advisory work on behalf of the estates continues to increase, and in consequence the research programmes have of necessity been curtailed. It is anticipated, however, that much valuable information will accrue from such work, much of which may be regarded as applied research. With regard to soil investigations, special attention is being paid to the development of more rapid methods of analysis, and the value of 'bunding' in the conservation of soil moisture is becoming more generally recognised. On the botanical side, numerous problems are arising as to the most economical method of tapping, the question of the optimum length of the rest period and the possibility of stimulating the yield over a short period, in connexion with old trees prior to their removal, being among the points upon which information is being collected. Increased yields have already been obtained by the practice of completing the tapping earlier in the day. In addition, fundamental research is in progress on the chemical and bacteriological aspects of latex and rubber. It has been shown that the presence of yellow pigment in latex does not affect the quality of sole crepe although owing to the demands of fashion it lowers the market value. Unfortunately, fractional coagulation, which adds considerably to the cost of preparation, is necessary for the production of the white form of crepe. The possibility of producing air-dried sheet as a substitute for smoked sheet and the questions of temperature and ventilation etc. of the drying sheds are also under investigation. Extensions in the field work have been made, and several lectures and conferences held with encouraging results.

The second International Congress of Soil Science was held in Russia on July 20–31, the first week at Leningrad and the second at Moscow. The countries from which members came included Chile, Czechoslovakia, Denmark, France, Germany, Great Britain,

Holland, India, Japan, Malaya, Palestine, Rumania, Spain, Sudan, Sweden, Switzerland, and the United States. The Congress was entertained at receptions and banquets by the provincial administration in Leningrad and by the central government in Moscow, and the hospitality shown left no doubt as to the desire of the authorities to make the visit as pleasant as possible. Three concerts and a cinema performance were specially arranged for the delegates, and a day in each city was set aside for sight-seeing. At the opening meeting in Leningrad, it was announced that Prof. K. K. Gedroiz, president of the Congress, was prevented by ill-health from attending, and it fell to Dr. D. J. Hissink, of Groningen, to act as president throughout the meetings. Apart from a few addresses of a more general nature, the work of the Congress was done by the six commissions into which it is divided, for soil mechanics and physics, chemistry, biology and biochemistry, fertility, classification and mapping, and applications to cultivation. Abstracts of the papers were distributed at the beginning of the Congress, and the full text will be printed in the *Proceedings* of the Congress, which are to be published by the Russian organising committee.

A SPECIAL feature of the Congress was the number of joint meetings of commissions on such subjects as physical properties, reaction, organic matter, soil utilisation, and alkali. The international soil map of the world has made considerable progress since the Congress of 1927, and further steps were taken for the mapping of the Mediterranean region, Africa, and South America. Visits were paid to a number of institutions in or near Leningrad and Moscow, and the foreign delegates were impressed by the energy with which these are being developed and by the generous financial provision for their equipment and support. Of special interest was the Dokuchaev Institute for soil science, containing a collection of hundreds of monoliths representative of the soil types of European and Asiatic Russia. At the conclusion of the Congress on July 31, many of the delegates left for a three weeks' tour arranged to cover the most important soil zones of European Russia. It was decided to hold the next Congress in 1935 in England, and Sir John Russell was elected president. Amongst other new officers, Prof. Robinson, of Bangor, succeeds Prof. Novak, of Brün, as president of the commission for soil mechanics and physics, and Dr. Joseph, of the Imperial Bureau of Soil Science, succeeds Prof. Marbut, of Washington, as president of the commission for soil classification, mapping, and morphology.

THE British Non-Ferrous Metals Research Association has secured a leasehold factory property in London, where it is proposed to centralise its offices and provide accommodation for a laboratory and workshops for its research and technical development departments. A special appeal for increased annual support and contributions to a headquarters' fund has recently been launched. The Association, founded ten years ago, has made steady progress under the direction of Dr. R. S. Hutton, and now carries out work for all sections of the non-ferrous metals industry on a scale of expenditure of £20,000-£25,000 per annum. It already has to its credit the discovery of new engineering materials and of methods of increasing efficiency of production, which should commend it to the metal and engineering trades. Dr. D. H. Ingall has just been appointed assistant-director and research manager of the Association, as from January next. Dr. Ingall is well known for his metallurgical research and administrative work, and as first principal of the Constantine Technical College, Middlesbrough, has been largely responsible for its equipment and organisation. Dr. O. F. Hudson will continue as senior metallurgist of the Association. Mr. G. L. Bailey, of the Metallurgy Section, Research Department, Woolwich, has been appointed, from Sept. 1, as development officer to fill the position recently vacated by Mr. S. J. Nightingale, who resigned to take up a post in industry.

SINCE Dr. John Hopkinson first suggested novel methods of charging for the electric light in his presidential address to the Junior Institution of Engineers in 1892, many such systems have been adopted in practice. In the journal for July issued by the A.E.G. Electric Co. of Victoria Street, London, a description is given of a 'two part tariff' prepayment meter which automatically records the consumer's payments and his consumption of electricity. This type of meter receives the two payments of the consumer, namely, his fixed monthly or quarterly payment and his payments for the energy taken. The latter charge is rated very low, so that once the fixed charge is paid the consumer finds that he can use his lighting or heating appliances most extravagantly at small cost. The objections urged against a one-part tariff is that the takings of the company in the summer time do not cover the running costs and that the consumers find that their winter bills are very high. From the supplier's point of view this system is very attractive, as he receives an appreciable revenue in the summer and the consumer finds that the winter bills are no longer too heavy. If the company ever desires to alter the price the meter can be easily adapted by simply changing the gear wheels. The only objection urged against this two-tariff method of charging is that it tends to make the consumer extravagant in his use of light.

THE chapter on the number of electrical accidents which have occurred during 1929, which is given in the chief inspector's report (Cmd. 3633, London: H.M. Stationery Office, 2*s*. 6*d*.), is instructive. Compared with the period 1910-14, there is no doubt that installations have been made very much safer and that devices that in certain circumstances can become dangerous are seldom used. We agree with Mr. Scott Ram, the senior electrical inspector of factories, that this is largely due to the making and enforcing of stringent regulations and also to the increased inspection by qualified officials. Although the use of electricity last year was four times as great as its average annual use during the period 1910-14, the number of accidents diminished. The maximum number of

recorded accidents during a year was 512 in 1913. Unfortunately, however, the number of fatal accidents from shock or burns with low voltages seems to be increasing. The number of accidents with pressures not greater than 250 volts last year happens to be the same with both direct and alternating current, but the latter are much more dangerous to life; whilst 21 of the a.c. accidents were fatal, none of the d.c. accidents were fatal. As the standard system of electric supply is now a.c., it will be seen how important it is that the regulations be enforced and the inspectorate strengthened. Several extraordinary accidents due to recklessness or absentmindedness are given, but in several cases employees have taken totally unwarranted risks in order that the supply to a few consumers may not be cut off for a brief period. In some cases they may possibly have done this with the connivance of their superiors. It has to be remembered that dangerous shocks occur with low pressures when the body makes contact with conductors of opposite polarity or more often with a live conductor and a good earth such as a water or gas pipe, the water in a bath or a damp wall or floor.

The Safety in Mines Research Board has just issued its eighth Annual Report, for the year 1929. Apart from the suggestion that this report should have been published at an earlier date, it may be looked upon as a satisfactory statement of a year's work. As usual, the bulk of the work is chemical and microscopic; there is no doubt that a thorough knowledge of the constitution of coal may lead to important results in the future, though its direct effect upon the prevention of accidents in mines may be but small. It is, however, highly satisfactory to see that the Board has at long last come to the conclusion that a number of the problems concerning safety in mines are not chemical but mechanical, and that it has accordingly appointed a highly qualified mining engineer to commence the investigation of such problems. The researches upon wire ropes that have been carried on under Prof. Dixon are another step in the right direction. The value of free international communication and collaboration in these matters is shown by the fact that the work at Sheffield, where they had the advantage of the presence for a considerable period of one of the workers of the United States Bureau of Mines, has resulted in a very satisfactory new apparatus, a modification of a well-known American apparatus, which is likely to prove very useful in rescue work. It is satisfactory to see that such international cooperation has been extended to France, and, although it does not appear in the present report, it is well known that similar arrangements are being concluded with Belgium. It need scarcely be said that most of the matters referred to in this report have been dealt with at length in the Safety in Mines Research Board Papers, issued during recent years.

According to a report in the *Daily Telegraph* of Aug. 12, Mr. Lansbury has announced the appointment of a Committee representing the Board of Education and the Office of Works to consider the question of the establishment of an open-air folk museum in London. The sum of £50,000 is promised towards the cost of the scheme. The terms of the report, while making no definite statement, suggest that the land in Regent's Park now held by the Royal Botanic Society under a lease which terminates in April 1932, but then to be added to the Park and, as announced in the House of Commons, thrown open to the public, may be available for the purpose. This land was one of two alternatives suggested by the Royal Commission on our National Museums in its report. Its suitability in situation and character has been strongly urged by the Committee appointed by the Royal Anthropological Institute with the object of securing the establishment of such a museum for England. It would appear that the proposal to be considered is on the lines suggested in the article on this question which appeared in the issue of Nature of Aug. 24, 1929, p. 289, and will follow the plan of the Continental folk museums in which exhibits are housed in peasants' dwellings typical of various periods re-erected in the museum grounds for that purpose.

In Great Britain it is difficult and costly to obtain for use before such bodies as field clubs and schools good educational films of Nature subjects. In California the State considers it to be good propaganda for fish and game conservation to issue free of charge, to responsible organisations within its territory, films depicting the natural history of the State. The reels are 1000 feet long, and illustrate great variety of fish, bird, and mammal life in its natural haunts, as well as commercial fisheries, trout cultural operations, and other human aspects. Not only does the Division of Fish and Game lend the films, but it is prepared also to supply lectures describing the pictures, many of which are designed for school use. A list of these motion picture films appears in *California Fish and Game* for April, pp. 152-156. It is full of interesting items and makes us wish that for our own information we could have the privilege of seeing many of them. Would that we could imagine the Ministry of Agriculture and Fisheries or any other British Government Department developing educational activities on lines so interesting and effective.

The Ministry of Agriculture and Fisheries has taken advantage of the recent meeting of the International Poultry Congress in London to recast the form of its agricultural publications. The majority of these will now appear as *Bulletins*, printed in good type and bound in attractive stiff paper covers with the titles overprinted in contrasting colours. Most of the volumes will be illustrated. We have received half a dozen of the *Bulletins*, which appropriately deal with various aspects of poultry-keeping, from general principles of poultry feeding to special instructions for the rearing of birds for the table or for egg production, and for the treatment of the most common diseases. In appearance and in the quantity and quality of their matter, these publications are a

vast improvement on the earlier pamphlets of the Ministry, and the prices, which vary from 6*d.* to 1*s.* 6*d.*, are very moderate. Since it is impossible even for the interested person to keep in touch with all the *Bulletins* as they appear, we suggest that a useful addition would be a list of the titles of such as have been published, printed on one of the cover blanks.

We have received from Mr. W. J. Lewis Abbott a friendly criticism of the paragraph in our issue of July 19 referring to Tertiary man in East Anglia. In pointing out the occurrence of a redundant 's' in 'lithoclasiology', he deplores our implied criticism of the term; but at the same time imputes to us a failure to appreciate the importance of the study which it designates that is far from the fact. He goes on to point out that all the examples of early man's handiwork to which he referred in his previous communication were his own discoveries. The flints found and accepted by Mr. H. B. Woodward at Thorpe, Norwich, were subsequent to Mr. Abbott's finds, as were Mr. Savin's discoveries in the Cromer Forest-Bed, *begun*, not renewed, in 1895, and it was Mr. Abbott's collection and not that of Mr. Savin that was exhibited at Burlington House. We regret that the facts were not clearly stated; but for this, we fear, Mr. Abbott's characteristically modest phrasing of his communication must be held responsible.

In the *Journal of the National Institute of Industrial Psychology* for July, Dr. A. Macrae discusses some of the problems involved in the selection of a career. He says that it is frequently assumed, if a child shows a definite vocational interest, he will necessarily have a real aptitude. Actually the facts are that while many people have been successful by following their inclinations, many others have failed. Practically every occupation makes many varying demands on the worker at it, and it is impossible for a child to feel drawn to some aspect of a particular kind of work which may, or may not, be the most important. To select, for example, the occupation of commercial traveller because one likes seeing new places is not of necessity to guarantee success, nor is a fondness for arguing a criterion of legal proficiency. In a study of a hundred boys leaving a secondary school, it was found that ten had no vocational inclination, forty-six seemed reasonably fitted for the work they had selected, and the others seemed definitely unfitted on the grounds of temperament, general intelligence, special mental capacities, health, and physique.

The one hundred and eleventh annual meeting of the Swiss Society of National Sciences will be held at St. Gallen on Sept. 11–14, under the presidency of Dr. H. Rehsteiner. The work of the meeting will be distributed over sixteen sections covering pure and applied science and medicine. The general programme includes addresses by Prof. Emil Abderhalden, of Halle a. S., on the significance and mechanism of ferments in Nature, Prof. P. Niggli, of Zurich, on ten years' work of a mineralogical and petrographic institute, Prof. R. Chodat, of Geneva, on the symbiosis of lichens and the problem of specificity, and Prof. C. Wegelin, of Berne, on endemic cretinism. Correspondence respecting the meeting should be addressed "Jahresvorstand der Schweizerischen Naturforschenden Gesellschaft in St. Gallen, Postfach St. Fiden No. 17".

The centenary of the opening of the Liverpool and Manchester Railway will be celebrated at Liverpool during the week Sept. 13–20. The celebrations have been arranged on a scale appropriate to the occasion by a committee under the joint presidency of the Lord Mayors of Liverpool and Manchester and Sir Josiah Stamp, the chairman of the London, Midland and Scottish Railway. Included in the programme is a great pageant of transport referred to as "probably the most ambitious pageant ever attempted in Great Britain". Some 3500 performers will take part in the pageant, the aim of which is to illustrate the progress of transport from the earliest times. A train of 1830 will convey visitors around a circular track specially laid down, and there will be an exhibition of models and historical material in St. George's Hall. The Libraries and Museum Committee of Liverpool has also arranged lectures for both adults and children. Mr. C. J. Allen will lecture on a century of railway travel; Mr. Dendy Marshall on the Rainhill locomotive trials of 1829, while Engr.-Capt. E. C. Smith will lecture on two hundred years of steam power on land and sea.

The eighteenth annual meeting of the Indian Science Congress will be held in Nagpur on Jan. 2–8, 1931. His Excellency Sir Montagu Sherard Dawes Butler, Governor of the Central Provinces, has consented to be patron of the meeting, and Lieut.-Col. R. B. Seymour Sewell, director of the Zoological Survey of India, will be president. Copies of papers to be offered to the Congress must reach the president of the section concerned not later than Oct. 15 next. The sectional presidents are as follows: Sir T. Vijayaraghavacharya, vice-chairman, Imperial Council of Agricultural Research, Simla (Agriculture); Dr. C. W. B. Normand, Director-General of Observatories, Poona (Mathematics and Physics); Prof. K. G. Naik, professor of chemistry, Baroda College, Baroda (Chemistry); Principal B. L. Bhatia, Government Intermediate College, Hoshiarpur, Punjab (Zoology); Prof. T. Ekambaram, professor of botany, Teachers' Training College, Saidapet, Madras (Botany); Dr. G. de P. Cotter, superintendent of the Geological Survey of India, Indian Museum, Calcutta (Geology); Rai Upendra Nath Brahmachari Bahadur, 82/3, Cornwallis Street, Calcutta (Medical and Veterinary Research); Mr. K. P. Chattopadhyay, Education Officer, Calcutta Corporation, Calcutta (Anthropology); Prof. G. C. Chatterji, professor of psychology, Government College, Lahore (Psychology). The General Secretaries of the Congress are Prof. S. P. Agharkar, 35, Ballygunge Circular Road, Calcutta, and Dr. H. B. Dunnicliff, Government College, Lahore. The Local Secretaries are Principal M. Owen, Victoria College of Science, Nagpur, and Rao Saheb S.N. Godbole, Victoria College of Science, Nagpur.

The eighth International Congress of the History of Medicine will be held in Rome on Sept. 22-27, with His Excellency Benito Mussolini as president of honour, Prof. Pietro Caparoni as president, and Profs. Bilancioni and Castiglioni as vice-presidents. The principal subjects for discussion will be (1) How Europe protected herself against leprosy in the Middle Ages, introduced by Prof. Jeanselme of Paris; (2) the medical and scientific relations between Italy and other European countries during the scientific renaissance in the sixteenth and seventeenth centuries, introduced by Prof. Karl Sudhoff of Leipzig and Prof. Arturo Castiglioni of Padua; (3) the necessity of making the study of the history of medicine a compulsory subject in all universities, introduced by Prof. Ladislaw Szumoski of Cracow. Numerous papers on miscellaneous subjects are also included in the programme, such as the problem of medical historiography, by Prof. Siegerist; van Helmont, by Prof. Ostachowski; Girolamo Cardano and Leonardo da Vinci, by Prof. Bilancioni; plastic surgery in Italy and Europe at the time of the Renaissance, by Dr. G. Sansevero-Roselli; and the influence of folk-lore on medicine, by Dr. Dan Mackenzie. The subscriptions, which should be sent to the treasurer, Prof. Vincenzo Rocchi, Corso Vittorio Emanuele 173, Rome, are 100 lire for members of the International Society of the History of Medicine and members of the Italian Society of the History of Medical and Natural Sciences, 150 lire for all other members of the Congress, and 50 lire for members of the families of those taking part in the Congress and medical students.

The sixth annual Norman Lockyer lecture of the British Science Guild will be given by Sir William Pope on Thursday, Nov. 13, at 4.30 P.M., in the Goldsmiths' Hall London (by permission of the Goldsmiths' Company). The president of the British Science Guild, the Rt. Hon. Sir Samuel Hoare, Bart., will take the chair at the lecture, the title of which will be announced later. The second annual Alexander Pedler lecture will be given by Lt.-Col. Sir David Prain on Wednesday, Oct. 22, at 5.30 P.M. "Science Discipline" is the general subject of this lecture, which will be given in Liverpool under the joint auspices of the University of Liverpool and the British Science Guild.

It is announced that two of the sectional presidents, Lord Eustace Percy and Prof. T. E. Gregor, who were to have presided over the sections of Education and Economics respectively at the Bristol meeting of the British Association next month, are unavoidably detained by business abroad. Their presidential addresses will be read in their absence.

We have received the annual report of the Calcutta School of Tropical Medicine, Institute of Hygiene, and the Carmichael Hospital for Tropical Diseases, 1929. The Director, Lieut.-Col. H. W. Acton, details the teaching and research work of the School and reviews recent advances in tropical medicine. This review, together with the reports of the work of the various departments, constitutes a valuable survey of the progress of tropical medicine. The attendances at the Calcutta Pasteur Institute for anti-rabic treatment numbered 10,219 for the year, a record, probably, for any Pasteur Institute in the world.

Applications are invited for the following appointments, on or before the dates mentioned:—An assistant at the Road Experimental Station of the Ministry of Transport, Roads Department, at Harmondsworth, near Colnbrook, Middlesex—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1 (Aug. 25). A full-time assistant lecturer in chemistry at the School of Mines, Treforest—The Director of Education, Glamorgan County Hall, Cardiff (Aug. 26). Entomological and mycological posts in the Cambridge University School of Agriculture, in connexion with a survey and other investigations on sugar beet pathology—The Secretary, Appointment Committee, School of Agriculture, Cambridge (Aug. 30). A biochemist in the Pathological Department of the Royal Victoria Infirmary, Newcastle-upon-Tyne—The House Governor and Secretary, Royal Victoria Infirmary, Newcastle-upon-Tyne (Aug. 30). Assistant lecturers in agriculture under the Education Committee of the Cornwall County Council—The Secretary for Education, County Hall, Truro (Sept. 5). A junior scientific officer in an Admiralty Establishment at Portsmouth—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (Sept. 6). An assistant lecturer and demonstrator in botany at the West of Scotland Agricultural College—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (Sept. 8). Nautical surveyors under the Board of Trade—The Senior Staff Officer, Establishment Department (Mercantile Marine Branch), Board of Trade, Great George Street, S.W.1 (Sept. 12). An advisory entomologist at the South Eastern Agricultural College—The Secretary, South Eastern Agricultural College, Wye, Kent (Sept. 13). A registrar of the University of Birmingham—The Secretary, The University, Birmingham (Sept. 15). A head of the gas engineering and supply department of the Westminster Technical Institute—The Education Officer (T.1), County Hall, S.E.1 (Sept. 30). Test assistants at the Royal Aircraft Establishment for, respectively, calculation and experimental work in connexion with aero-engine investigations, work in connexion with the technical development of aeronautical instruments and small precision apparatus, and work in connexion with strength tests and experimental work on aircraft structures and materials—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants. A full-time teacher of woodwork and pattern-making at the Smethwick Junior Technical School—The Director of Education, 215 High Street, Smethwick. A whole-time radiologist at the General Hospital, Wellington, New Zealand—"Radiologist, Wellington", c/o The High Commissioner for New Zealand, 415 Strand, W.C.2. A senior clinical assistant and clinical tutor and a non-resident clinical assistant in the department of ophthalmology of the Royal Infirmary of Edinburgh—The Superintendent, Royal Infirmary, Edinburgh.

Research Items.

A Cypriote Threshing Sledge.—In *Man* for August, Mr. J. Hornell describes a very ancient type of implement known as a *dukani* or 'threshing sledge' used by the Cypriote farmer for threshing grain. This is a broad board about six and a half feet long, of which a length of nearly five feet is straight, the remaining portion at the forward end being inclined upward at an angle of 18°-20°. The breadth varies in different dukani from 24 in. to 27 in. The board is made up of two planks joined lengthwise edge to edge. Except for a margin of eight inches at either end the bottom surface is studded with many rows of sharp-edged flints inserted by their bases in long and narrow triangular slots. In one example there were twenty-two rows in one plank and twenty-three in the other. Each row consisted of ten flints in each plank, each row being set alternately to the one in front and the one behind. The total for the two planks was 450 flints. The thickness of the two boards is 2½ inches, but the thickness is cut down slightly from the fore-end and the size of the flints for a short distance anteriorly is smaller. They range from 1¾ in. to 2¼ in. in length and from 1⅛ in. to 1⅞ in. in height. The shape of the flints is roughly triangular with two long knife-edged sides and a thick and massive butt. The projecting edge is arched and one face is always convex, the other keeled. The slots into which the flints are inserted are made by a chisel of peculiar form. When all the flints have been inserted in the slots, hot pitch is poured along the rows just as the ancient Egyptians fastened the flints in their sickles with a plaster setting. The sledges are drawn by two oxen flint side downward over the threshing floor, which is thickly strewn with sheaves. The driver sits on a chair placed midway between the transverse battens. This form of threshing appliance is a survival of the Roman tribulum which persists in Syria, Asia Minor, Georgia, and Greece. In some parts of Spain and the Canary Islands it is in use without the flints as the straw is required whole.

The Physiology of Hibernation.—In a useful summary of results bearing upon the hibernation of animals, P. A. Gorer regards hibernation and æstivation as manifestations of the property of living organisms of withdrawing from an unfavourable environment (*Biol. Rev. and Biol. Proc.*, Cambridge Phil. Soc., vol. 5, p. 213, July 1930). However, since it is impossible to regard any one condition of the environment as being responsible, he turns to the physiological condition for the common factor, and examines the various suggestions which have been made from this point of view. The metabolism of hibernators, which is the lowest metabolism required to maintain the existence of protoplasm, is bound up with a marked decrease in oxygen consumption, but cannot be explained, as has been argued, by the varying solubility of carbon dioxide at different temperatures. In the metabolic changes the nervous system is involved, and a résumé of results shows that it is of primitive structure and remarkable adaptivity in hibernating mammals, in which decerebration causes comparatively slight effects on the heat-regulative and postural reactions. Apart from the nervous system, the endocrine system, and particularly the pituitary, must be looked upon as the governor of metabolism amongst the higher animals, and a general truth appears to be that hibernation is associated with a change in the water content. The conclusion of hibernation, like its onset, varies from animal to animal, even amongst related species, and is associated with accumulation of waste products and sometimes with changes in moisture, the energy required being obtained perhaps by shivering, perhaps from the activity of the liver.

Type Specimens of Myctophine Fishes.—Mr. Albert Eide Parr, in his paper "Notes on the Species of Myctophine Fishes represented by Type Specimens in the United States National Museum" (*Proc. U.S. National Museum*, vol. 76, Art. 10, No. 2807, 1929), gives a detailed account of the fishes belonging to the sub-family Myctophinæ which are deposited in the United States National Museum. The result of this investigation is a thorough revision and partial or complete redescriptions, with diagrammatic figures, of a large number of fishes belonging to this group. The whole is based on Lütken's and Brauer's system of classification by the photophores which has recently been used by Tåning (1918, 1928) in his "Mediterranean Scopelidæ" and "Synopsis of the Scopelids of the North Atlantic". The work of Tåning and that of the present author fit in well together, dealing as they do with fishes chiefly from very different areas. Mr. Parr is of the opinion, however, that the subdivision of the *rafinesquei*-like forms of the genus *Diaphus* into entirely separate species according to the definitions rendered by Tåning is absolutely impracticable, although it may be of great value for differentiating ecological races or local subspecific forms within restricted oceanographical areas.

Nematode Parasite of the Frit-Fly.—In the *Philosophical Transactions of the Royal Society*, B436 (June 28, 1930), Dr. T. Goodey describes a new genus and species of Nematoda, namely, *Tylenchinema oscinellinae* from the frit-fly (*Oscinella frit*) of oats. It appears that ensheathed larvæ and the young adults of this worm occur in oat stems. The male worms ultimately die after impregnating the females, while the latter enter the frit-fly larvæ, most probably by boring their way through the skin. They remain in this host during the time the latter completes its metamorphosis, and are afterwards to be found in the body-cavity of the newly emerged flies. The female worms grow within their host into comparatively large sausage-shaped organisms: their gonads occupy most of the body space and reproduction is viviparous. Large numbers of motile larvæ of both sexes are discharged into the hæmocœl of the fly, and these creatures bore their way into the gut of that insect, finally reaching the exterior via the anus. The presence of the *Tylenchinema* within the fly inhibits the normal growth of the gonads to a very marked degree and the sex cells, both male and female, fail to develop. In the few cases that were observed in which the gonads of the host were normal, the parasite proved to have been degenerate. The parasitisation does not directly entail the death of the host, and infected individuals fly about and visit their host plants (oats and grasses). It is during this period that the Nematode larvæ become deposited on the plants. They make their way into the stems where the frit-fly larvae are feeding, and here they undergo moulting, and become young adult males and females. The latter, after impregnation, enter the frit-fly larvæ, and so the cycle is carried on. This interesting Nematode has been found by Dr. Goodey to have a wide distribution in England and Wales. Frit-flies of the stem generation were found to be parasitised to about 14 per cent and those of the panicle generation about 5 per cent. This Nematode, therefore, is to be regarded as an organism the relation of which to agriculture is of a beneficial character.

Bryozoan Fauna of the Galapagos Islands.—Dr. Ferdinand Canu and Dr. Ray S. Bassler have described a particularly interesting collection from the dredgings of the United States Fish Commission steamer *Albatross*, preserved in the United States National Museum, from a few stations in the vicinity of the Galapagos Islands (No. 2810, *Proceedings of the United States National Museum*, vol. 76, Art. 13, 1930). Amongst the many species described ten are common to the Gulf of Mexico and to the Galapagos, indicating an ancient communication between the Pacific and Atlantic and the recent formation of the Isthmus of Panama. There are not many of these forms common to the two regions. In the Galapagos the great southern current has modified considerably the nature of the plankton and all the marine fauna. Simple forms, such, for example, as *Aplousina filum*, which are indifferent to the thermic influences, have alone been able to persist. Sometimes species so far only found fossil in the Gulf of Mexico are found living in the Galapagos Islands. Of fifty-three species determined and studied, twenty-nine are new, and four new genera belonging to the Cheilostomata are here created, three of which are peculiar to the region. So far no species occurring in South America have been recognised in the Galapagos Islands.

Recent English Earth-movement.—The widely adopted conclusion that the British Isles have undergone no change in level since Roman times has been frequently confronted by the claim for recent subsidences along the coast. The existence of Roman sites and pottery below sea-level is not conclusive of a general movement, since the land surface may be lowered by the shrinkage of water-logged ground after drainage. Mr. C. J. Gilbert has summarised in a short paper—"Land oscillations during the closing stages of the Neolithic depression" (Second Report of the Commission on Pliocene and Pleistocene Terraces, Union Géographique Internationale, Florence, 1930, pp. 93-101)—evidence of changes of level of Romney Marsh, the Thames Estuary, and the Arun Valley in Sussex, indicative of a marked post-Roman subsidence. The Roman settlements are now 8-9 ft. below ordinary high tide level at Westminster, 16½ ft. at the Albert Dock, 17 ft. at Crossness, and 14-15 ft. at Tilbury. Mr. Gilbert concludes that at Romney Marsh there have been three well-marked subsidences. The first was part of the widespread and well established Neolithic depression; it was during the Neolithic, as it was followed by an uplift that produced surfaces occupied by Neolithic man. The second subsidence was post-Neolithic and pre-Roman. The third was from the eleventh to the thirteenth centuries A.D. and led to the final submergence of the Goodwin Sands, the devastation of the south-western part of Romney Marsh, and the destruction of Broomhill and of the older outlet of the Rother. Mr. Gilbert claims the agreement of these movements with those on the coast of Flanders and those recently adduced by Mr. R. D. Oldham from the Rhone delta. Nevertheless, despite the wide range of these changes, he regards them as local and as due to oscillations of the land. If they were due to changes in ocean level parallel phenomena would be widespread around the British shores and on the Continent; such he concludes "manifestly do not exist". The earth movements of Scandinavia, he states, have been fundamentally divergent from those of Britain.

Peat Profiles in North America.—An investigation of thirty-four peat bogs in the region from Niagara to Nova Scotia has been made by V. Auer, and his results appear in *Mem.* 162 of the Geological Survey of Canada, 1930. The materials described include inorganic, organic, limy, and jelly-like oozes and *Carex*, *Amblystegium*, *Sphagnum*, grass, and forest peats. The stratigraphical succession indicates that the lower layers were formed during a warm dry (Boreal) period; this was followed by moister conditions with deciduous trees (Atlantic); then a dry period succeeded (sub-Boreal); and finally a moist and comparatively cool climate is suggested (sub-Atlantic). In a general way, as indicated by the terms in brackets, the changes correspond to those of post-glacial Europe. Peat profile studies in Maine (*Jour. Wash. Acad. Sci.*, April 4, 1930), and in the Puget Sound Basin of Washington (*Ibid.*, June 4, 1930), are recorded by A. P. Dachnowski-Stokes. The South Lubec peat of Maine is a member of the 'highmoors', and is characterised by a three-layered succession derived from marsh, forest, and sphagnum moss plant communities. The marginal soils show that podsolising processes are now active. The Washington peat-lands are of two groups: low moor, with two- or three-layered limnogenic profiles, with a reed and sedge assemblage at the surface; and acid oligotrophic peats with sphagnum moss at the surface.

Geology of Queensland.—Some interesting problems of Queensland geology are discussed by J. H. Reid in "The Queensland Upper Palæozoic Succession" (*Pub.* 278, Queensland Geol. Surv., 1930). It is concluded that between the base of the Devonian and the top of the Permian there is evidence of three effective folding movements with trends nearly parallel to the present coast. The first of these was probably in the Lower Devonian, but determination of the age depends on correlations that have not yet been satisfactorily established. There followed a Middle Carboniferous movement without thrusts, and still later a more intense orogeny of late Permian age which led to thrusting from the oceanic side. This was accompanied or succeeded by intense igneous activity, to which the origin of the metalliferous deposits of the Queensland copper-gold province is reasonably thought to be related. Glacial formations of three distinct, though not well determined, ages are established: Upper Carboniferous, Lower Permian, and Middle Permian. It is important to notice, however, that the deposits are all apparently the result of material transported by floating ice from a land area lying to the south. The suggested periods correspond to those in New South Wales, where terrestrial glacial deposits occur in the 'Permo-Carboniferous'.

Oil-well Deviation.—The subject of oil-well deviation, or 'crooked holes' as it is known in the industry, is one which has come very much into the limelight since the technique of deep drilling attained its present high standard. With a shallow well, deviation from the vertical either mattered little or, if it was a bad case, it could be corrected by various devices known to the driller. But where wells reach to a mile or more in depth, the cumulative error of deviation becomes too great to be ignored; hence the necessity of careful control on drilling wells and of survey of those or existing wells where deviation is thought to be excessive. Actually a straight hole of any depth is almost an impossibility, even with the most modern plant, since the attitude and nature of the rocks penetrated influence the run of the bit; for example, if a hole already 15°-20° from the vertical is suddenly continued in soft shale, dipping 60°-65°, no check being placed on behaviour and tendencies, the probability is that the bit will run down dip, that is, at increased deviation, so that not only is there a serious error in supposed depth of the well from the surface, but also important horizons such as oil sands may be missed

altogether, to say nothing of the consequent straying of subsurface calculations. This subject was dealt with ably at some length by Mr. D. P. Rees at a meeting of the Institution of Petroleum Technologists in May last. Apart from the engineering factors involved, the author showed that the method now generally adopted to counter the effect of deviation of wells in oilfields is to run a survey in those wells which are being drilled, where there is any chance of the deviation being sufficient to upset calculations of oil and water horizons. Although the time taken to survey a well being drilled may interfere somewhat with progress, this is more than made good by the value which increased accuracy of record has in the economic working of the field as a whole.

Variometer for Measuring Vertical Magnetic Force. - The Danish Meteorological Institute has recently issued a further part (Nos. 8, 9) of its *Communications Magnétiques*; No. 8 consists of an extremely able article by the Director, Dr. la Cour, on a new form of variometer for the vertical magnetic force. He has called this the 'Godhavn' balance, in celebration of the institution, by Denmark in 1928, of the observatory at that station in Greenland (69·2° N., 53·2° W.). The principal features of the new instrument are: (1) the magnet, mirror, and knife edges consist of a single piece of tungsten steel, the length of the magnet being about 6 cm. and the total weight about 2·5 grams; (2) the magnet is placed in a sealed vessel in dry clean air at a low pressure (about 100 mm. of mercury), thus preserving it from any influence of moisture or dust: (3) the influence of temperature changes on the magnet is compensated optically, by a prism supported by a bimetallic suspension and placed outside the vessel containing the magnet, thus enabling the prism to be adjusted without affecting the magnet; (4) the price of the instrument is relatively low, being about £25 without the compensator, or £33 with it. The detailed account of the instrument is full of examples of careful thought and ingenuity in its design and use.

Gyromagnetic Effect for a Paramagnetic Substance. --When a body is magnetised, electron theory requires that it should simultaneously acquire a mechanical spin, small even for ferromagnetic substances, about the magnetic axis. The extremely difficult experimental determination of the spin generated in a specimen of the paramagnetic substance dysprosium oxide by this effect is described by W. Sucksmith in the July issue of the *Proceedings of the Royal Society*. The methods used for iron and nickel were too crude to be applied directly in this case, and it was found necessary to set up a resonant torsional vibration of the specimen by applying an alternating magnetic field of the same period, and to take great precautions both to avoid ferromagnetic impurity and to obviate electrostatic and other disturbances. Even then, with a logarithmic decrement of about 10^{-3}, and magnetic fields of some hundred gauss, the amplitude of vibration was only about ten minutes of arc. The result obtained is that the Landé splitting factor (g) of spectroscopic theory is $1{\cdot}28 \pm 0{\cdot}07$ for the ion Dy^{+++} in dysprosium oxide, in excellent agreement with the value 4/3 which corresponds to the state ${}^6H_{15/2}$ predicted by Hund to be the most probable for this ion.

Soft X-Rays and Electrons in Crystals.—When soft X-rays are excited by bombarding solids with electrons or when the secondary electrons emitted from the surface are examined, evidence is obtained that a complex system of energy levels exists which cannot be correlated with the Bohr systems for the atoms of the solid. The experiments are difficult, and the results obtained by different investigators not very consistent, but it is pointed out by Prof. O. W. Richardson, in a paper in the July issue of the *Proceedings of the Royal Society* (p. 63), that if it is assumed that there is present in a crystal a class of structure electrons which are neither free nor associated with individual atoms, frequencies of the observed order of magnitude can result. Pursuing the analogy that a crystal is like a large molecule, Prof. Richardson remarks that the structure electron levels should be built up in a very similar way to that of the levels to which the source of a system of vibration bands in molecular spectra is attributed, and shows that there is in certain cases a relation between the magnitudes of the energy levels observed, and the integral numbers. The quantum mechanics of electrons in crystals has also been developed recently by P. M. Morse (*Physical Review*, June 1, p. 1310), but although it accounts well for many details of the experiments of Davisson and Germer, it has still to be considered in relation to soft X-ray phenomena.

Design of Radio Receivers. An excellent report containing a review of recent literature on the design of radio receivers has just been published by His Majesty's Stationery Office (price 5*s*. net). It has been prepared at the National Physical Laboratory for the Radio Research Board. It gives a clear indication of the lines along which future research may be profitably undertaken. It will be of special use to workers who are studying the properties of radio receivers. All the abstracts of papers given are critically examined, and so workers will be able to tell whether it will be useful for them to make more detailed examination of the papers or not. The bibliography is practically complete from 1916 to 1929. Only those parts of the early literature of the subject prior to 1916 are included which are of outstanding importance. Periodic phenomena do not completely represent the operation of a receiver which is constantly being acted on by complex waves of non-periodic form. We know, however, that from a practical point of view, a knowledge of the steady state phenomena suffices for practical purposes in a great many cases. Unfortunately, the design of short wave amplifiers is as yet almost entirely empirical. The behaviour of a three-terminal thermionic tube at very high frequencies gives rise to phenomena which have not been satisfactorily explained. All the work on audio frequency amplifier design has been directed towards obtaining a linear frequency characteristic. Recent improvements of loud speakers are in the direction of obtaining a uniform frequency response and this is the ideal solution. The operation of the loud speaker might also be corrected by using suitable electrical filter circuits, but this would only be a partial solution. If we design the amplifier to correct the defects of the loud speaker, then the two would form an inseparable combination and so this solution would not be advisable.

Estimation of Water in Methyl Alcohol.—A method for the detection and estimation of small quantities of water in methyl alcohol is described in the June number of the *Journal of the Chemical Society* by D. C. Jones and S. Amstell. It depends on the fact that the critical solution temperature in the system methyl alcohol *cyclo*-hexane is very sensitive indeed to the presence of water in the alcohol. *Cyclo*-hexane is readily obtained, can be purified easily, and has in its melting point a very sensitive criterion of its own purity. A quantity of 0·01 per cent of water in the alcohol produces a rise in miscibility temperature of 0·15°.

The Topographical Changes Accompanying Earthquakes and Volcanic Eruptions.*

THE twenty-sixth, and nominally the last, part of the *Publications* of the Earthquake Investigation Committee appeared in 1908. Though we have had to wait more than twenty years for the number that should have preceded it, it may be said at once that geologists have gained greatly by the delay, for Prof. Imamura, the well-known secretary of the Committee, has been able to avail himself of many valuable recent observations, and especially of those of the Kwanto earthquake of 1923 and the Tango earthquake of 1927, and the eruptions of the Usu-san in 1910 and the Sakura-jima in 1914. It is not too much to say that his memoir is likely to prove one of the classics of seismology. In these pages Prof. Imamura has described the changes that have occurred about the times of so many as 26 Japanese earthquakes, in 12 of which (from 1891 to 1927) the changes have been measured by one or more series of subsequent precise levellings. As might be expected in a young country like Japan, the changes are of two kinds, which he terms chronic and acute. The latter, of course, are associated with earthquakes. The chronic changes may prepare the way for the acute earthquake changes, but an example of remarkable interest, investigated by the late Prof. Yamasaki, is given in which chronic changes occur apparently alone.

The district in question lies along the coast of the Japan Sea in the provinces of Etigo and Sinano, and extends about fifty miles to the east of the lofty Hido range. It consists of two large blocks separated by a deep depression. The series of precise levellings were carried out first in 1894, and they have been repeated in 1927. During this interval, in 1897 and 1918, there were two strong shocks, but with neither was there any formation of new clefts or fault-lines. Yet a comparison of the two surveys has revealed the facts that, with a few trifling exceptions, both blocks have subsided, and that in each the amount of subsidence decreases gradually from west to east. In the western block, it is 94 mm. at the west end and 38 mm. at the east end, where, along an old fault, it suddenly increases to 113 mm. In the eastern block, the subsidence is 96 mm. at the west end, while at the east end there is a rise of 4 mm., succeeded, again along an old fault, by a sudden depression of 70 mm.

In the present notice, it is only possible to refer briefly to some of the interesting conclusions at which Prof. Imamura arrives. While most of the earthquakes with which topographical changes were associated were of destructive strength, a few (such as the Susaka earthquake of 1897 and the Oomati earthquake of 1918) resulted in no loss of life. As a rule, elevations of the land are confined to formations of Tertiary or more recent age, depressions to formations of pre-Tertiary age. The changes considered consist, for the most part, of discontinuous tiltings of consecutive mosiac blocks, but, in some earthquakes, as in the Kwanto earthquake of 1923, there is also a rotational movement about a vertical axis or bodily displacement in a vertical direction. Discontinuous tiltings of contiguous blocks result in the formation of faults or flexures along their boundaries. In local earthquakes, such a fault-system is simple, but, in great earthquakes, it may be extremely complex. Sometimes, as in the Mino-Owari earthquake of 1891, it consists of several segments arranged *en échelon*, in the earthquake mentioned crossing the whole of the Main Island. In others, as in the Kwanto earthquake of 1923 and the Tango earthquake of 1927, it is distributed over the epicentral area along pre-existing tectonic lines.

In the Kwanto district, there have been four great earthquakes during the last two thousand years, shortly after the beginning of the Christian era, and in 818, 1703, and 1923. Prof. Imamura summarises the changes at the last epoch and probably at each of the other epochs, as consisting of the following stages: (1) a practical absence of any tilting for a century or so; (2) slight chronic tilting for a few decades in the direction opposite to that in which it afterwards occurs, accompanied by many local earthquakes; (3) slight reversed tilting, with more frequent and stronger local earthquakes; (4) pronounced acute tilting accompanying a disastrous earthquake; and (5) a repetition to and fro of the tiltings, which gradually diminish in magnitude until they cease.

The changes that precede, accompany, and follow volcanic eruptions have been measured in only two eruptions. The earlier changes are similar to those that occur before earthquakes. In the immediate neighbourhood of the volcanoes, they consist apparently of an upward bulge of the land, but essentially they are discontinuous tiltings of mosaic blocks as in great earthquakes. The principal difference lies in the leisurely way in which the volcanic changes take place as compared with the quick and sudden changes that occur with earthquakes. C. Davison.

Estimating Stream Flow from Evaporation.

MR. FOLSE'S monograph referred to below * embodies the data and results of a research begun in 1912 and continued until 1925 by the late Dr. John F. Hayford and completed by the author. To a certain extent, as stated by the author, it overlaps *Publication* No. 317 by Dr. Hayford.

The object of the investigation was to formulate laws governing the flow of streams and rivers on the basis of more specific laws of evaporation. The numerous intensive studies of evaporation pans of small area have been supplemented by an examination on the full scale of Nature and under natural conditions. For this purpose, each of the Great Lakes was considered as an evaporation pan and from day to day evaluations were made of the change of content, the income and outgo including evaporation. From these observations it was found possible to segregate that part of the outgo which is evaporation, and to determine the laws of evaporation, and their application to the problem of stream flow.

The observations consisted of the daily mean elevations of the water surfaces, barometric pressures, wind velocities, temperatures, vapour pressures, and rainfalls.

The outcome of the investigation claimed by the author is briefly as follows:

(1) An evaporation formula has been derived which enables one to estimate the daily evaporation from any free, open surface of water in terms of air temperature, vapour pressure, and wind velocity.

(2) An estimate has been made of the constant part of the run-off into each of the Lakes Michigan, Huron, and Superior, from their respective drainage areas, and

* A new Method of estimating Stream Flow: based upon a new Evaporation Formula. By J. A. Folse. (Publication No. 400.) Pp. xi+237+22 plates. (Washington, D.C.: Carnegie Institution, 1929.) 5 dollars.

certain knowledge with reference to the variable parts of the run-off in each case has been obtained.

(3) A reasonably accurate numerical expression has been obtained from the effects of barometric pressures on the elevation of the water surface at the Marquette Station on Lake Superior, and constants enabling one to compute the hourly or daily effect of a wind of any velocity and direction upon the water-surface at the same station.

(4) The knowledge gained in (1) and (2) has been applied to the estimation of evaporation losses from land surfaces, and the combined effects upon stream flow.

Space does not permit any detailed description of the investigation or of the evaporation formula. They have, however, involved an immense amount of work and many thousands of calculations.

In applying his conclusions to stream flow in the second part of the treatise, the author assumes that the evaporation from a land surface follows the same laws as, and bears a constant ratio to, the evaporation from a free open water surface in each watershed. In his expression for the 'normal' flow of any stream there appear eleven terms, one of which is termed the 'constant' part of the flow, and the remaining ten terms functions of the rainfall in varying periods extending to 257 days preceding the day of the observation. The coefficients for these terms have been determined and the results tested against actual stream flow records.

The impression gained by a study of this work is that the author has unquestionably advanced the study of the laws of evaporation from water surfaces, but that in its application to stream flow he has devised a process on assumptions which are not fully justified by results. H. L.

The Origin of the Irish Fauna and Flora.

WHILE the flora and fauna of Ireland are essentially those of Great Britain, differing chiefly in the absence of Germanic species, the occurrence of the so-called Lusitanian and American elements has made Ireland an area of special interest to biologists and geologists who have sought to trace the history and origin of its floral and faunal life. The Lusitanian flora, as is well known, has its continental centre in the Iberian Peninsula, while a correspondingly small faunal group, comprising no large animals, has a somewhat similar distribution. In Ireland most of these Lusitanian plants and animals are found in the south and south-west, although some extend northwards. The American element, even smaller than the Lusitanian, is separated from its main area of distribution by the Atlantic Ocean. Reference may be made also to an Arctic-Alpine element which, although better represented in Britain, is fairly widely distributed in Ireland. The absence of certain British species and the presence of Lusitanian, American, and Arctic-Alpine species are some of the outstanding facts which any complete theory of the origin of the Irish fauna and flora must explain.

So long ago as 1846, Edward Forbes, in a paper dealing with the geographical distribution of plants and animals in the British Isles, was among the first to inquire into the geological changes affecting their area, and since then biologists have repeatedly attacked the problem from different angles. In seeking a solution to the problem it has always been recognised that the most important factor was the intervention of the glacial period, but the effects of the changes thus brought about have been very variously estimated. Some have advocated complete extermination of the Irish fauna and flora; others have believed in a considerable survival dating from Miocene times. In these discussions the voice of the geologist has not been sufficiently heard, and biologists will welcome, therefore, the authoritative views recently expressed by Prof. J. Kaye Charlesworth.[1] The author describes the complete burial of Ireland beneath the Pleistocene ice-sheet at the maximum of glaciation as an indisputable fact, and the possibility of survival during glacial times of even the smallest part of the Irish fauna and flora as we know it to-day must be definitely excluded from our calculations.

Survival in some unknown southern or western asylum beyond the limits of the ice has been, however, frequently postulated and commonly accepted among biologists. This question is largely a geological one, and Prof. Charlesworth enters into it fully, examining critically the evidence regarding changes of sea-level during the Pleistocene, and the climatic conditions of the ice-free strip, if any such existed. The problem of the glacial sea-level is complicated, but obviously of fundamental importance. When glacial conditions set in, Ireland was an island with a coast line very similar in position and level to that of the present time. During glacial times the sea-level did not remain constant, otherwise all possibility of survival could be "most categorically denied". From all the available evidence, too detailed to summarise, the conclusion is reached that during the glacial period the sea-level around the Irish coasts was lowered by about 50 fathoms. To the south of Ireland this line encloses an extensive area which might provide a place of refuge, but taking the most favourable view for survival, Prof. Charlesworth thinks that probably only arctic and boreal species persisted on the southern ice-free strip. To the west there was no ice-free area.

Immigration of the present Irish flora and fauna took place, therefore, subsequent to maximum glaciation. The view is held that a considerable fauna and flora, including Lusitanian species, reached Ireland during the "Aurignacean Oscillation" when the ice-sheet withdrew from the southern half of the island. Prof. Charlesworth leaves to biologists to decide what species may have survived the ensuing Early Magdalenian Glaciation when the ice readvanced to the line of the 'South Irish End-moraine' running from Wexford to the mouth of the Shannon. For immigration into Ireland a post-glacial land connexion with Great Britain existed, but the connexion was never complete. The 'bridge' between Ireland and the Scottish mainland was severed by the Sound of Jura, while the more southerly 'bridge' between Ireland and Wales was broken by a narrow strait or wide river west of Anglesey. Over this broken drift plain the greater part of the Irish fauna and flora seems to have entered, and clearly some accidental dispersal would be necessary to effect the crossings. The later submergence during the "Atlantic Period" prevented further immigration, and those forms which continued to extend their range westwards in Britain after that date could enter Ireland, if they did so at all, only by chance dispersal.

Prof. Charlesworth's exposition of the geological factors which must be taken into account is of the greatest importance to biologists and provides a much safer starting-ground than any hitherto available for tracing the history of Irish plant and animal life.

J. R. MATTHEWS.

University and Educational Intelligence.

THE emphasis laid by American educationists to-day on the importance of relating institutions, whether university, college, or school, as closely as possible to the actual daily life of the people, may be seen in the rapid increase (to which attention is directed in *Education Bulletin*, 1929, No. 30) in the number of schools adopting the form of organisation known as the 'general shop' for providing in the school curriculum instruction in a number of different manual activities for pupils of twelve to fifteen years of age. The bulletin points out that modern life has become so complex and production so highly specialised that the consumer has, apart from some such school instruction, little opportunity to learn much about trade operations, materials, or manufacturing processes. The 'general shop' training is not for actual skill in the trades represented, but rather for an understanding and appreciation of values in the final product, and incidentally for the acquisition of a certain amount of unspecialised 'handyman's' dexterity.

NATAL University College celebrates this year the twenty-first anniversary of its foundation. In a handsome commemoration number of the College magazine appears an interesting retrospect by Prof. J. W. Bews, chairman of the College Senate and Dean of the Faculty of Science of the University of South Africa, whose connexion with the College has been continuous since 1910, except for a break of two years, 1925–27, when he held the chair of botany in the University of Durham. The progress of the College since the War has been rapid, the number of students (420 in 1930) having been multiplied nearly tenfold. It was established in Maritzburg, the old capital of Natal, but its work was in 1922 extended to Durban in co-operation with the staff of the Natal Technical College. Durban as a commercial city and seaport has developed at such a pace that it has far outgrown Maritzburg in importance, and seems destined to have a great future in which the College will take a prominent part.

THE Department of Agriculture for Scotland has approved the following appointments at the Hannah Dairy Research Institute, Ayr: *Director*, Dr. Norman C. Wright; *Secretary*, Mr. T. W. Gibson; *Research Assistant in Physiology*, Mr. S. Morris. Dr. N. C. Wright was educated at Christ Church, Oxford, and at Gonville and Caius College, Cambridge. He received the degree of Ph.D. at Cambridge for work on the calcium metabolism of dairy cows. In 1924 Dr. Wright joined the staff of the National Institute for Research in Dairying at Reading, and in 1926 he was awarded a Commonwealth Fund Fellowship, working for two years in the United States, first in the Department of Dairy Industry at Cornell University, and later in the Bureau of Dairying of the United States Department of Agriculture. He was the first member of the staff of the Hannah Institute and has been largely responsible for the general development of the work of the Institute. His research work has been largely in the field of applied physiology. With Mr. W. L. Little he demonstrated for the first time the reduction in the lime content of the blood in cases of milk fever, an observation which forms the basis of the new calcium treatment of this disease. He has also published papers on the physiology of milk secretion, the significance of 'bulk' in the rations of dairy cows, and the occurrence of tuberculosis in cattle. Dr. Wright succeeds Prof. E. P. Cathcart, who will retain his active connexion with the Institute in the position of vice-chairman of the Committee.

Historic Natural Events.

Aug. 24, 358. Great Storm in Black Sea.—A violent storm, accompanied by a great inundation of the sea, occurred in the Black Sea; at noon the sky was quite dark. Macedonia and Asia Minor suffered severely. The storm was followed by a great earthquake.

Aug. 24-26, 1905. Rainstorm in Eastern Ireland.—Rain began to fall shortly after 9 P.M. on Aug. 24 in Dublin, and continued steadily for 34 hours, during which period about 4 inches of rain fell generally, the amount increasing to 5·50 inches on high ground at Bray. Floods caused a great deal of damage to roads and bridges, while part of Bray was submerged to a depth of 4 feet, and the electric light generators were put out of action.

Aug. 25, 1839. Red Snow.—Although the occurrence of patches of red colour in old snow had been known for long, one of the earliest detailed determinations of the true nature of the colouring matter was that made by R. J. Shuttleworth in 1839 (*Edinburgh New Philosophical Journal*, 1840, p. 54). He examined microscopically melted red snow from the neighbourhood of the Hospice du Grimsel, and found that the red colour was due to a number of minute organisms, both Flagellata and Algæ. The snow was described as having a rosy hue, like very pale blood; being old, it was granular, and the colouring matter was contained in the intervals between the particles, giving the surface a veined appearance. The colour extended to a depth of several inches or a foot.

Aug. 25, 1890. Thunderstorm in Eastern Alps.—At about 4 P.M. a thunderstorm occurred at Pesaro in north-eastern Italy, travelling very rapidly north-eastwards across the Adriatic and eastern Austria so far as Vienna. The rainfall was not especially heavy, the largest total being only 3·5 in., partly in the form of hail, but the storm was notable for the sharp rise of pressure, at Pesaro more than 5 mb., which accompanied the onset of the storm, and the violent winds. At Pesaro the wind velocity reached 80 miles per hour, and at Pola 62 miles per hour. Much damage was done, trees uprooted and houses unroofed; many ships were wrecked. The violent winds blew from the south-west, parallel with the track of the storm and at about the same speed.

Aug. 25, 1925. Lightning at San Joaquim Valley, California.—On Aug. 25, 1925, a lightning storm broke over the valley. A flash of lightning struck a 750,000-barrel oil reservoir of the Shell Company at Coalinga and caused an immense fire. The heat developed by the fire was sufficient to raise 1000 cubic kilometres of air through 10° C. Owing to this intense heat, whirlwinds were formed over the fire, and D. Brunt found that the energy supplied by the fire was ample to account for the formation of violent tornadoes. This lightning stroke cost the fire insurance companies more than one million dollars.

Aug. 26, 1346. Crécy Storm.—It is related that just before the battle of Crécy a shower broke over the French and English armies, and largely disabled the Genoese crossbowmen with the former by wetting their strings. The English archers, keeping their bows in cases, were not affected, and it has been said that this incident influenced the course of the battle.

Aug. 26-28, 1883. Great Eruption of Krakatoa.—The great eruption of Krakatoa, in the Sunda Strait, attained its maximum phase during these days. In a series of great outbursts, two-thirds of the island disappeared. The sounds of the explosions were heard at Diego Garcia (2375 miles) and Rodriguez (3080 miles). Waves of longer period cracked walls at

Batavia (100 miles), and others, registered by barographs, travelled at least three times round the earth. Sea-waves, causing the loss of 36,500 lives in Java and Sumatra, were registered by tide-gauges in French and English ports. The dust drifting in the upper atmosphere gave rise for months afterwards to sunset glows of great brilliancy.

Aug. 26, 1912. The Norwich Floods.—Heavy rain began to fall in East Anglia in the early morning of Aug. 26 and continued until the morning of Aug. 27. The total period was not much longer than twenty-four hours, but in Norwich and neighbouring parts the fall exceeded 7 in. and reached 8·09 in. at Brundall and 8·25 in. at Sprowston. The fall of 7·31 in. entered to Aug. 26 is the heaviest known in a day in the east of England. The area with more than 5 in. was estimated as 1039 square miles, and in an area of 1939 square miles the volume of rain exceeded 150,000 million gallons. Serious floods occurred in several of the eastern counties, and particularly in Norwich, where the water level in the flooded part of the city reached a higher level than on any previous occasion. Many bridges were destroyed, and road and rail traffic was dislocated over a wide area.

Aug. 28, 1722. Hurricane in Jamaica.—This was the greatest hurricane on record in Jamaica, and devastated the whole island. It began at Port Royal at 8 A.M. and lasted fourteen hours, during which time the rain was incessant and the storm veered all around the compass. In Kingston most of the buildings were thrown down or much shattered, including the church. The fort suffered very much, and some of the guns were washed into the sea. Out of fifty vessels in port only four men-of-war and two traders were saved, and about 400 lives were lost. After the hurricane there was a calm and the air was so poisoned by the smell of decaying bodies that an epidemic broke out.

Aug. 29, 1776. Fog at Long Island.—After the defeat of Washington's army by the British in the battle of Long Island, the Americans were apparently caught in a trap, for their retreat was cut off by a British fleet in East River. That night, however, a dense fog blinded the British look-outs, and the American army was able to escape across the river to New York.

Aug. 29, 1885. Sirocco at Palermo. An intense sirocco began at Palermo at 1 A.M. with a strong hot wind. At 9 A.M. the temperature had risen to 104° F., and at 1 P.M. the thermometer in the shade stood at 121° F., by far the highest ever recorded in the town. The distribution was, however, very irregular, differing by 20° in different parts. The air was very dry, the relative humidity being only 10 per cent.

Societies and Academies.

EDINBURGH.

Royal Society, July 7.—**A. J. Clark, C. P. Stewart, and R. Gaddie**: The metabolism of the heart. The frog's isolated heart, perfused with Ringer, maintained a regular contraction for 48 hours, and more than 90 per cent of the energy was derived from a non-carbohydrate source. The sugar consumption of the heart could not be increased materially by addition of glucose, serum, and insulin to the perfusion fluid. There was a small but steady excretion of nitrogen from the heart, and the oxidation of the protein equivalent of this nitrogen would have corresponded to about half the oxygen consumption of the heart. The respiratory quotient of hearts perfused with Ringer's fluid lay between 0·80 and 0·85, and did not rise above 0·90 when insulin and sugar were added. The results suggested that the isolated frog's heart used proteins as its chief source of energy.—**E. T. Copson**: The definite integrals of interpolation theory. The cardinal function of interpolation theory, introduced by Prof. Whittaker, has been represented by definite integrals in two distinct ways, the first due to W. L. Ferrar, the second to Ogria and J. M. Whittaker. In this note the relation between these representations is discussed.—**J. Geronimus**: On some persymmetric determinants.

PARIS.

Academy of Sciences, June 30.—**Bigourdan**: The observatory of Méchain, in the rue Vieille-du-Temple.—**A. d'Arsonval**: An X-ray tube of the Coolidge type working at 400,000 volts.—**G. Cerf**: A class of Backlund transformations leading to partial differential equations of the second order with double characteristics.—**Mme. N. Samoïlowa-Jachontowa**: The calculations of planetary perturbations by means of a new independent variable.—**Raoul Gautier**: Concerning Tempel's first periodic comet, 1867 II.—**H. Muraour** and **G. Aunis**: The comparison of calculated explosion pressures with experimental explosion pressures. In a previous paper the authors have shown that there is good agreement between the experimental explosion pressures, corrected for cooling by the walls, and the pressures, starting with the Nernst-Wohl specific heats. This work has now been supplemented, working with a powder giving a very high explosion temperature (3600° C.). Bearing in mind that a large extrapolation was necessary for the specific heats, and that the calculation of the amount of dissociation was somewhat uncertain, the differences between the calculated and observed pressures, −0·6 per cent to +3·4 per cent, are satisfactory.—**Horia Hulubei**: A photo-electric cell for the ultraviolet. Method of sensitising. Palladium was chosen for the metal, sensitised by active hydrogen. With an accelerating potential of 120-480 volts, the threshold was about 2850 A.—**Henri Marcelet** and **Henri Debono**: Spectrographic analysis of the various types of fluorescence of olive oil, observed in ultra-violet light.—**Marcel Guillot**: The relation of several reactions carrying down polonium with the existence, in the form of colloidal precipitates removable by the centrifuge, of insoluble derivatives of this radio-element. In all cases, where more than 97 per cent of the polonium can be carried down by a foreign precipitate, it is possible by centrifugation, without the addition of a foreign element, to prove the precipitation of an insoluble compound of the radio-element.—**A. Sanfourche** and **L. Rondier**: The irreversible reduction of the oxides of nitrogen by sulphurous acid.—**A. Astruc** and **M. Mousseron**: The microanalysis of the calcium ion. The method is based on the precipitation of the calcium as the double nitrite $CaK_2 . Ni(NO_2)_6$, washing with aqueous acetone (20 per cent) and alcohol-ether, and reduction of the nitrate to ammonia. The method gives good results for amounts of 0·3-1·0 mgm. of calcium.—**P. Brenans** and **K. Yeu**: Bromo-diiodophenols, symmetrical trihalogen compounds.—**G. Darzens**: Styrallyl-allylacetic acid and its conversion into a tetrahydronaphthalene derivative.—**Wyart**: The study of heulandite by means of the X-rays.—**Pierre Bonnet**: The thrust in the south trans-Caucasian geosyncline.—**Marcel Roubault**: The glacial formations of the Néoubielho massif (Hautes-Pyrénées).—**P. Russo**: The dipping of the Middle Atlas under the plain of Moulouya (North Morocco).—**H. Derville**: Lunel marble: its varieties.—**C. Dauzère**

and **J. Bouget**: The influence of the geological constitution of the soil on the points where hail falls. In a hailstorm near Bagnères, the heaviest fall of hail was on siliceous schists and metamorphic rocks: limestones are protective against hail. These results confirm the views previously published by the author on the influence of the constitution of the soil on the distribution of hail.—**Pierre Dangeard**: Observations on the living protoplasm of Algæ.

CRACOW.

Polish Academy of Science and Letters, May 5.—**T. Wazewski**: Asymptotic Jacobians and the change of the variables in multiple integrals.—**S. K. Zaremba**: Remark on the singularities of systems of differential equations not solved with respect to the differentials.—**J. Pagaczewski**: The provisional elements of the variable stars Algolides, 40, 1929 Eridani and 43, 1929 Orionis.—**Wl. Gorczyński**: The degrees of transparency of the atmosphere for solar radiation on several oceans and some other regions.—**W. Swietoslawski** and **S. Bakowski**: Some experiments on the velocity of evaporation of liquids on a surface of heated platinum.—**Mme. H. Blaszkowska-Zakrzewska**: The velocity of evaporation of liquids on heated metallic surfaces.—**K. Dziewoński** and **A. Obtulowicz**: The benzoyl derivatives of fluorene.—**M. Ramult**: The Cladoceran fauna of Pomerellie.—**M. Ramult**: A case of gynandromorphism in the species *Alona affinis*.—**Wl. Szymonowicz**: The innervation of the tactile hairs of the seal.—**B. Petschenko**: The grafting of Jensen's rat sarcoma on the mouse.

GENEVA.

Society of Physics and Natural History, May 22.—**Th. Tommasina**: The experimental proof of the existence of the ether given by that of the ultra-red dynamical rays. The author recalls the phenomena observed on a radiometer with triple glass walls; he attributes the motion to the action of ultra-red rays which he calls dynamic, and considers that his experiments prove the existence of the ether. The latter is the agent conveying the energy which, in contact with matter, can take any of the forms known in physics.—**R. Galopin**: Some new minerals in the scoria of blast furnaces. One of the minerals studied, from its optical properties, belongs to the peridote group; the other suggesting the mixtures in variable proportion of gehlenite and akermanite studied by Fergusson and Buddington.

June 5.—**L. Duparc**: The molybdenite deposit of Azegour (Morocco). The molybdenite is contained in grenatites, a product of contact metamorphism of a granite. From the research work on this deposit, it would appear that there are important quantities of this mineral, in proportions reaching more than 3 per cent.—**E. Briner** and **J. Deshusses**: Researches on the formation and decomposition of cyanogen. Study of the chemical action of electric discharges. Submitting the carbon-nitrogen system to heat and to electric discharges of various kinds, the authors have been unable to prove the production of cyanogen. The velocity of decomposition of cyanogen at various temperatures has been measured; it is insufficient to lead to the complete destruction of any cyanogen which might have been formed. The absence of the formation of this substance can be explained by the peculiarities of the chemical action of electric discharges.—**N. Danoz**: The calculation of the Newtonian potential of a certain heterogeneous sphere. The author establishes a formula giving the value of the potential at a point inside the sphere.

SYDNEY.

Royal Society of New South Wales, June 4.—**F. W. Booker**: A review of some of the Permo-Carboniferous Productidæ of New South Wales, with a tentative reclassification. The several forms comprised in *Productus Brachythaerus*, G. B. Sowerby, 1844, were reviewed in the light of recent researches. They belong to a distinct genus *Terrakea* containing at least four species.—**H. G. Raggatt** and **H. F. Whitworth**: The intrusive igneous rocks of the Muswellbrook-Singleton District. (1) Introduction. Three groups of intrusive igneous rocks are recognised as follows: (1) Alkaline basic sills; (2) plugs; (3) dykes and small sills. The alkaline sills include the Savoy, Plashett, Carrington, and Fordwich intrusions, each containing acid and basic phases and presenting an interesting study in magmatic differentiation. The plugs consist of basaltic types of rock poor in felspar and rich in ferro magnesian minerals. Many contain nepheline. The dykes and small sills are numerous. The former include porphyritic and non-porphyritic types of rocks. The sill rocks resemble very closely the latter type. The age of the first two groups is almost certainly Tertiary; the third group requires further study before the age can be stated. Apart from their scientific interest, a study of the intrusive igneous rocks has considerable economic interest in relation to coal reserves, and the possible occurrence of oil and gas.—**A. R. Penfold**: The essential oils of *Zieria Smithii* (Andrews) and its various forms. This Rutaceous shrub grows in moist situations throughout New South Wales, Victoria, and Queensland. The chemical composition varied according to the locality from which plant material was obtained. Yield of oil from Queensland material is about 0·5 per cent on fresh material or 0·9 per cent on air-dried leaves. The principal constituents are safrol with a little methyl eugenol (70-80 per cent), together with d-a-pinene, sesquiterpenes, etc. Material from Narrabeen, New South Wales, contains 95 per cent methyl eugenol, and the phenol esters from Toronto material are a mixture of elimicin and safrol.

Eugenic Sterilisation.

SOME of the young people of Germany would have us believe that much of the time that can be spared from their more materially fruitful exploits is given over to singing a song which they call "Deutsche Jugend, heraus". Its language, borrowed from historical romanticism, permits, if it does not foster, a certain diversity of interpretation, and some lines with a frankly Christian significance may even be omitted at the discretion of the singer. Claim to popularity is thus made more catholic.

> Wollt Ihr ein neues bauen
> mit Händen stark und rein,
> in gläubigem Vertrauen
> lasst dies die Losung sein:
> Den Feind in eigner Mitte
> gefällt in ernstem Strauss. . . .

Moralists, it is easy to see, may use these lines to assist them in focusing attention upon that enemy in their midst distinguished as the *beam*, while the nationalist may recognise more immediately its particular referability to the communistic *mote*.

We are assured, however, that the resiliency of this *credo* unites rather than divides, and such demonstrations as we have enjoyed tend to reinforce the assurance audibly. But we cannot help wondering what will happen in the world when the youth of one country or another not only present accessible enemies in their patriotic songs but also define them with scientific precision.

The real enemies of mankind are made, yearly, more and more accessible to attack by science, and if it were not for the protective screens, intangible and often fantastic, thrown up by the unscientific for whom nakedness, even the enemy's, still seems to possess terrible powers, mankind might subjugate very speedily its worst foes. But if, as Sir Walter Fletcher has lately pointed out, a mere ailment, like cancer, has only been made accessible to scientific study through the lifting of foolish and superstitious taboos, how can we expect the direr social maladies to be approached courageously? A protective hedge of errors and superstitions hems them in on every side, so rank and poisonous that it seems that even science is infected and intimidated while it attacks.

How else is it possible to explain the demand just put forward * by a committee of the Eugenics Society for permissive legislation which would take a whole generation to achieve a reduction in the incidence of mental defect not of a hundred, not of fifty, not of twenty-five, but, problematically,

* Committee for Legalising Eugenic Sterilisation. Eugenics Society, London, 1930.

of seventeen per cent ? Between our people and the realisation of this slender benefit stands " an ambiguity of the law " which the Society proposes to remove. A person may, with consent, be sterilised in the interests of his *own* health. In the interest of the public health, present or future, he may not be sterilised. By a curious legal inversion, the 'willing mind' of the individual cannot take away the offence against the public even should he be prepared to save it from all possibility of contamination by his own progeny. The offence consists in a 'maim' which deprives the individual, or so it may be contended, of martial courage, and the State of a vessel, however unsuitable otherwise, for this same virtue. To contentions of this sort, surely the monosyllabic genius of Mr. H. G. Wells's latest novel has supplied the only effective answer.

To meet the practical situation, the committee proposes a Bill legalising eugenic sterilisation. This would authorise the mental deficiency authority or superintendent of an institution to sterilise a mental defective, subject to the consent of the parent or guardian and of the Board of Control, and of the spouse if the defective is married. In the case of defectives deemed capable of giving consent, sterilisation would not be performed otherwise than with this consent. It would authorise the voluntary sterilisation of a person about to be discharged from a mental hospital for the insane as recovered, again with the added consent of Board and of parent, guardian, or spouse; and it would legalise voluntary sterilisation for the sole purpose of preventing the transmission of hereditary defect seriously impairing physical or mental health or efficiency.

Five members of the committee and another contributed to the *Lancet* for July 19 a letter defending this policy. The defence combats the assertion that if every certifiable mental defective had been sterilised twenty or thirty years ago it would have made little appreciable difference to the number of mental defectives existing to-day. It repeats a sentence of the committee's report urging that " if all the defectives in the community could be prevented from having children the effect would be even on the most unfavourable genetic assumptions with regard to defectiveness, to reduce the incidence of mental defect by as much as 17 per cent in one generation ".

Obviously a 17 per cent reduction in the incidence of mental deficiency is more desirable than a 17 per cent increase. But do the committee's proposals ensure this reduction ? Clearly, no. The words quoted promise at least that reduction if the fertility of *all* living mental defectives is prevented. The committee's proposals, with their emphasis upon the voluntary principle, by no means ensure that the 300,000 certifiable mental defectives in England and Wales would be sterilised. Who must consent ? (1) The patient, if he is capable. (2) The parent or guardian. (3) The spouse if the patient is married. (4) The Board of Control. The calculation, it is true, is based on two assumptions " highly unfavourable " to the effectiveness of the proposals—that the genetic factor responsible for defectiveness (primary amentia) would be much 'carried' and would only rarely produce manifest defectives, and that defectiveness is uniformly distributed throughout the community. (The fertility of defectives also is assumed to be that of the average of the population.)

How unfavourable, on the other hand, are the chances of permission ? Nothing is gained by attempts to write off opposing assumptions. A figure is a figure, right or wrong.

Again, is a 17 per cent reduction all that eugenic science can promise ? Disregarding altogether those so-intelligent defectives who will strive to serve the country by seeking this minor mutilation, is it the institutional class that constitutes the chief danger to society ? Prof. MacBride (NATURE, Jan. 11, 1930, p. 40) says emphatically that this but touches the fringe of the problem. " The defectives most dangerous to society are those who are never confined in institutions at all ! The high-grade defectives are just able to support themselves in the lowest paid and most unskilled occupations, and no civilised government would take the responsibility of confining them, and so they go on propagating large families as stupid as themselves." His idea of penal sterilisation, a punishment " for the economic sin of producing more children than the parents can support ", is one which becomes more and more difficult to apply as more and more ways are devised by the State for screening the individual from biological estimation.

Is there not a real danger that the advocates of such legislation as here may mistake the assent of the political machine for victory ? If assent were gained, would it not be much more accurately determined as the hall-mark of failure ? It is not the assent of the State, but the initiative and creative power of the State, that is needed to secure essential progress, and that will not exist until our legislators of all parties or of any party derive their inspiration from the cultivation of natural knowledge.

Biochemistry for Students.

(1) *The Essentials of Chemical Physiology: for the Use of Students.* By Prof. W. D. Halliburton, Dr. J. A. Hewitt, and Dr. W. Robson. Twelfth edition. Pp. xii + 383. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1929.) 9*s*.

(2) *A Text-book of Biochemistry: for Students of Medicine and Science.* By Prof. A. T. Cameron. (Churchill's Empire Series.) Second edition. Pp. xi + 482 + 2 plates. (London: J. and A. Churchill, 1929.) 15*s*.

(3) *A Course in Practical Biochemistry: for Students of Medicine.* By Prof. A. T. Cameron and Prof. Frank D. White. (Churchill's Empire Series.) Pp. x + 222 + 4 plates. (London: J. and A. Churchill, 1930.) 8*s*. 6*d*.

(1) AFTER more or less of a dependent career, biochemistry has at last attained what one might call 'Dominion status' among the community of the biological sciences, and the three small volumes under review are a token of this attainment. One of them, "The Essentials of Chemical Physiology", which was first published in 1893, now appears in its twelfth edition, the original author, Prof. W. D. Halliburton, the pioneer of biochemistry in Great Britain, being assisted in its production by two representatives of the modern school, Dr. J. A. Hewitt and Dr. W. Robson. For training medical students in what will be of real value to them in their professional work as physicians, the book is excellent. The guidance by the experienced teacher of a difficult subject is seen in the selection and arrangement of the experiments, and these are described in such a way as to give the student opportunity of testing for himself the broad principles of the subject, as well as of acquiring some practice in those quantitative methods which are used as aids in clinical diagnosis.

To acquire perfect accuracy in the use of quantitative methods would take much more time than the already overcrowded medical curriculum can afford. Nor, indeed, were the time available, would it be of much value to try to do so; nevertheless, it is most important that the physician should learn enough about how the methods are carried out, so that he may be in a position to know what emphasis to place upon the results submitted to him by the clinical chemist. It is through a lack of this knowledge that many physicians fail to put a proper value on the assistance they can derive from the biochemist. They are apt to look upon him merely as a technician whose work is done when he has reported the results of the often laborious, and sometimes useless, chemical analyses assigned to him. They fail to realise that intimate collaboration between physician and biochemist, not only in the diagnosis but also in the conduct of the case, would be invaluable. It is this principle that a modern course in biochemistry should teach, and the present volume furnishes an admirable stepping-stone leading to its realisation by the student.

The theoretical matter is sufficient in scope to connect the purely chemical with the physiological aspects of the subject. Occasionally, as is a common fault with all elementary texts in a growing science, dogmatic statements are made, when really the truth is not known with certainty. For example, it is stated on p. 149 that regurgitation of the duodenal contents is the *normal* method by which the acidity of those of the stomach is prevented from rising too high. Is this proved?

The printing of the experiments in bold type is an excellent idea.

(2) The other two volumes are of a somewhat different type. One of them is the second edition of a "Text-book of Biochemistry", and the other, which now appears for the first time, a practical manual to go with it. The text-book differs from Halliburton's "Essentials" in being not restricted to the needs of the medical student. It treats the subject on somewhat broader lines, and will be found most useful as an introductory text for those who may be looking forward to a career in biochemistry itself, or are studying it with the view of entering one or other of the many non-medical sciences (agriculture, bacteriology, food chemistry) in which its principles are applied.

By a judicious use of small print, much of the more advanced matter is kept by itself and may be omitted without disturbing the sequence of the text. Although the author is a chemist by training, he has succeeded admirably in incorporating with the purely chemical material the biological and the medical applications of his subject. Here and there, however, the physiological teaching is somewhat unorthodox, as, for example, on p. 143, where we are told that the intestinal juice is largely secreted by the glands of Brunner.

The book is clearly written, the subject matter very well selected and arranged, and sufficient attention is given to the discussion of unsolved problems of biochemistry to arouse the interest of the better type of student, for whom also a short bibliography at the end of each chapter affords a guide to further reading. The early appearance of a second edition is evidence of the demand for

such a book, and the author may justly be proud of his success.

(3) The " Practical Biochemistry ", by the same author in association with F. D. White, contains a series of laboratory exercises requiring at least fifty-six periods of three hours each to carry out. This exceeds considerably the time available for such work in the great majority of the medical schools of Great Britain, so that, if the text were adopted, considerable pruning would be necessary by the teacher. The course is arranged in two parts; the first dealing with qualitative procedures and the second with quantitative. In the latter, only one approved method has been selected for detailed description of each substance estimated, brief references being also given to other methods. As an accurate and useful laboratory guide to the fundamental experiments of biochemistry, the book is excellent.

An Optical Miscellany.

(1) *Introduction to Physical Optics.* By Prof. John Kellock Robertson. Pp. vii + 422 + 6 plates. (London: Chapman and Hall, Ltd., 1930.) 20s. net.

(2) *Traité de polarimétrie.* Par Prof. Georges Bruhat. Pp. xvi + 447. (Paris: Éditions de la *Revue d'optique théorique et instrumentale,* 1930.) 65 francs.

(3) *Guide de l'ouvrier en verres d'optique de précision.* Par Col. Charles Dévé. Pp. xvii + 258. (Paris: Éditions de la *Revue d'optique théorique et instrumentale,* 1930.) 36 francs.

(4) *Zur Geschichte der Zeissischen Werkstätte bis zum Tode Ernest Abbes.* Von Moritz von Rohr. Mit Beiträgen von Max Fischer und August Köhler. Pp. viii + 120 + 10. (Jena: Carl Zeiss, 1930.)

THESE four books represent some aspects of the widespread domain of 'Optics'. (1) Prof. Robertson's " Introduction to Physical Optics " will appeal more to the theoretician than to the experimentalist. Its tendency is to present an idealised picture in which mundane difficulties disappear, as is no doubt quite necessary if some slight ideas of relativity and wave mechanics are to be introduced before the end of a not-too-long book. It is, however, a very lucid and direct treatment in which the modern developments of the subject of the interaction of radiation and matter receive their due balance of attention. The early parts comprise a clear discussion of lens and mirror optics (treated on the 'wave' basis), interference, and diffraction. The mathematics is limited to simple algebra and trigonometry.

While it is good to find that the sign conventions used in the lens and mirror problems are in agreement with those of technical practice, it is greatly to be desired that authors would not alarm students by remarks such as " in any problems dealing with refraction at a spherical surface, it is better not to work from a formula but from fundamental considerations ". If the use of unsymmetrical formulæ such as

$$\frac{n}{p} - \frac{1}{q} = \frac{n-1}{r}$$

were only replaced by the symmetrical form

$$\frac{n'}{q} - \frac{n}{p} = \frac{n'-n}{r}$$

the need of injunctions about "fundamental considerations" would not dismay people whose time is limited.

We wish that it could be realised that the physical difficulties, over which books such as this glide so easily, have an educational value in themselves. Let the student realise that the slits actually used in Young's experiment may be big enough to contain thousands on thousands of atomic sources of light in their breadth (let alone their length), and what becomes in his mind of the " well defined wave fronts " which spread out (according to this book) from a single slit? These conceptions really are a little too facile, in view of the matters dealt with in the concluding chapters. Do we really understand 'interference' so well; more especially interference under large path differences?

(2) Prof. Bruhat in his " Traité de polarimétrie " writes for serious experimenters who are interested in exact measurements. To make the subject intelligible to a wider circle, he includes a discussion of the principles of the wave theory. His experience evidently allows him to assume very little exact and systematic knowledge on the part of most beginners in this field, so that all points in connexion with instruments and their functions are explained with the greatest thoroughness and care. As he admits himself, some parts of the book are " over-developed " with respect to the requirements of certain classes of reader, but, as new applications of polarimetric measurements are continually being described, the collection of cognate material in a single volume will find few to condemn it.

After dealing at length with instruments and sources of light, he discusses the chief phenomena of rotary polarisation and measurements in this connexion. Some attention is given to the theories of stereo-chemistry; then normal and anomalous

rotary dispersion and dichroism are discussed. The treatment is introductory and non-mathematical. After this preparation a special section is naturally devoted to the determination of sugar contents, and some final sections deal with the rotary effects of crystals and magnetic rotary polarisation.

This book illustrates in a most striking manner the vast developments of such special subjects which have taken place within the last half-century. The comprehensive bibliography is a very useful feature. We may envy Prof. Bruhat the catholicity of his reading and knowledge, especially when his well-known works on electricity and thermodynamics are remembered.

(3) Col. Charles Dévé's little guide for the worker in optical glass is one of the latest of the useful series published by the Institut d'Optique, to which Prof. Bruhat's "Polarimétrie" also belongs. It should be very useful to those who have to control the grinding and polishing of glass. The section on the mechanical theory of the grinding process is very original and suggestive. This subject is a matter which has received very little systematic attention (at least, if it has, the results have never been published), so that this analysis and explanation should appeal to the practical worker who can arm himself with the necessary technical dictionary and thus make shift to overcome the language difficulties, which are somewhat more formidable in connexion with workshop and commodity terms than in ordinary scientific literature.

While the chapters on practical tests for optical glass and finished prisms, etc., will offer some useful hints, they by no means exhaust the subject. We are surprised to hear that the "méthode des ombres portées" is "incomparablement plus sensible" than a suitable form of the Foucault test. The "vérifications à l'atelier" include many useful methods, but include no mention of the interferometer, which has long since ceased to be a purely laboratory instrument. The auto-collimator is important enough in practice to receive more attention. These suggestions are, however, not made to minify the value of a book on a subject in which the available literature is so scanty.

(4) Turning to an item of greater human interest, Prof. M. von Rohr writes an interesting history of the Zeiss Optical Works up to the time of the death of Abbe. It will appeal to all who have even a slight knowledge of optics, and are also interested in the development of technical industry.

Here we trace the early influences surrounding the founder of the firm, Carl Zeiss, which doubtless led to his desire for the co-operation of such a partner as he found most fortunately in Ernst Abbe.

Abbe himself was indifferent to publicity, and but little of his scientific work is published; but these pages give some glimpses of his unremitting activity and painstaking thoroughness—especially in the account of his early experiments on the mode of the formation of the image in the microscope. This firm found the secret of success in team-work by competent individuals under adequate leadership. If this was a singularly effective recipe in the latter half of last century, it is now a *sine qua non*.

L. C. Martin.

Law, Causation, and Reality.

Identity and Reality. By Émile Meyerson. Authorized translation by Kate Loewenberg. (Library of Philosophy.) Pp. 495. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Co., 1930.) 16s. net.

Identität und Wirklichkeit. Von Émile Meyerson. *Deutsch von Kurt Grelling nach der 3 Auflage des Originals.* Eingeleitet und mit Anmerkungen versehen von Prof. Leon Lichtenstein. Pp. xl + 534. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1930.) 21 gold marks.

THE publication of English and German translations of Dr. Meyerson's work (1908) is a somewhat tardy recognition of its importance. The present versions are based on the third edition of 1926, which is practically that of 1912 with notes on subsequent developments in science. Although this may seem to restrict the value of the book, the additions accord sufficiently well with the author's analytical investigation of the two cardinal principles which research has once again thrust into the forefront of debate—universal causation, and universal conformity to natural law. What constitutes the ultimate ground of their presumed universality? Is it the inductive outcome of observation and experiment, always imperilled, therefore, by the Damoclean sword of revolutionary discovery or even the negative instance? Or does its validity consist in some quite irrefutable, and in a sense *a priori*, characteristic of thought, which finds an adequate foundation in the very structure of reality?

Most scientific workers would unhesitatingly reject the second suggestion as a mere vestige of antiquated speculation, discredited equally by its anthropomorphism and by every sound principle of methodology. On the other hand, it must be clearly realised that the deductive, and again in a sense *a priori*, proofs of mathematics are acquiring

a steadily expanding applicability within almost every field of research; and this to such a degree that Prof. Whitehead, in "Process and Reality", regards his own survey of science as ample justification for appealing to rationalism and metaphysics. Similarly, Dr. Meyerson maintains that the scientific concepts of conservation, mechanism, and inertia arise not only from the two sources of 'lawfulness' and '*scientific causality*', but further, as regards causation, from *a priori* factors which, though they certainly remain concealed by science, must not, therefore, remain ignored. On the contrary, it is precisely these factors which, like an 'unconscious' incessantly though invisibly directing scientific activities, have actually determined their slow historic meanderings from their Ionian origins to to-day, alike in the purely mechanical and the non-mechanical spheres. Thus all the dominant concepts "rest upon what constitutes the foundations of the human mind" (p. 409).

From this point of view Meyerson explicitly affirms that "metaphysics penetrates all science, for the simple reason that it is contained in its point of departure. We cannot even isolate it in a precise region." It follows, therefore, that "the ontological character of scientific explanation is ineffaceable" (pp. 377, 385); and although Hume's scepticism and Kant's agnosticism are outstanding anticipations of the prevailing scientific reaction to this contention, recent correspondence in these columns clearly expresses the suspicion (to say the least) that the science of to-day, and still more of the future, must criticise its own self-denying ordinances if it is to do itself justice by securing adequate self-consistency. The ultimate issues are undeniably debatable and profoundly subtle and involved; nevertheless, it is the expansion of science that is forcing them more and more irresistibly into consideration. Now, however unexpected the advances may be, they still retain an ineradicable element of continuity; and this implies that earlier developments may illuminate future problems to an important degree. Certainly the present volume is an inquiry into the nature of knowledge as such; but the author possesses an unusually wide and detailed acquaintance with past scientific theory and research, which he has incorporated in a systematic and impartial critique of current principles directly pertinent to reigning controversies.

It appears to be rapidly becoming a vital question whether experiment and induction may not tend to make science too extremely Baconian; and Meyerson cites a frank opinion of Liebig's in support of his own plea, favoured among others by Poincaré and Duhem, for pure theory with all its epistemological implications. He begins with an important distinction between the concept of natural law, postulating determined changes in properties, and the idea of causation, implying the constant equality of original properties to the final, when changed conditions are duly taken into account. Thus causality comes to involve "the principle of identity applied to the existence of objects in time"; it is, therefore, "profoundly different from that of lawfulness" (p. 43).

In its instinctive search for adequate explanation, then, science has consciously or unconsciously pursued this ideal of absolute identity, as expressed in increasingly intelligible forms of atomism, conservation, and inertia; and this raises the fundamental problem as to how far this principle must be carried. Meyerson proceeds to maintain that, despite all attempts to displace explanation by description, or to employ symbolism, science remains "profoundly impregnated with the search for causality" in the foregoing sense. It is, of course, obvious that all constants and relativistic absolutes are immutable identities; hence the further crucial issue whether these constants must be progressively reduced to a minimum. If not, how are they interrelated? And how reconciled with the patent diversities of Nature, with teleology and indeterminancy?

Here also Meyerson is insistent that "only the foundation of mechanism, the explanation of phenomena by motion, is and will be really eternal" (p. 415). Yet though science seems committed to an endless transition to more and more refined types of mechanism, no mechanism can ever be final; all mechanical hypotheses ultimately become self-contradictory and even absurd; while to carry the causal principle to its conclusion involves "the annihilation of the phenomenon"—a tendency visible in the reduction of natural process to pointer readings and equations. Equations, again, are essentially reversible, conflicting therefore with the irreversibility inseparable from Carnot's principle. Finally, "the end of the reduction can only be irrational" (p. 409), even though scientific instinct demands the minimum of an irrationality it can never evade. Yet can we agree that reason leads only to irrationality? Is not 'super-rational' a more fitting term? To conclude with a simple analogy, is the calculus irrational to the child mind, or is it not rather super-rational? And may not this best describe the aspect which reality must ever present to scientific thought?

J. E. TURNER.

Our Bookshelf.

American Civil Engineers' Handbook. Editor-in-Chief: Thaddeus Merriman; Associate Editor-in-Chief: Thos. H. Wiggin. Fifth edition, thoroughly revised and enlarged. Pp. iii + 2263. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1930.) 40*s.* net.

FOR the past twenty years or so "Merriman's Pocket Book"—to give its original title—has been familiar as a useful compendium of American practice in civil engineering, sharing the field with Trautwine and some others across the Atlantic and following in the footsteps (more or less) of Molesworth, Kempe, and other British publications. Now it has reached a fifth edition, and in consequence of the lamented death of Mansfield Merriman, the original compiler, it is issued under the names of his successors, Thaddeus Merriman and T. H. Wiggin. As in the case of previous editions, a number of associate editors have assisted in dealing with separate sections.

Naturally there are changes—partly in the material and partly in its disposition. The new edition contains 2263 pages, or 268 more than its immediate predecessor. The order of the sections has been modified somewhat to suit an alternative arrangement by which the book can be obtained, if desired, in two volumes instead of one. The present number of sections is 22, and they comprise all departments of civil engineering work and even encroach in some measure, as is inevitable, on the neighbouring domains of mechanical and electrical engineering; but, except in a few casual and fragmentary paragraphs, they do not intrude appreciably into aeronautics.

The difficulties of selecting and arranging material for inclusion in a handbook (the term pocket book is no longer applicable to "Merriman" and has been discarded since the third edition) are considerable if not almost overwhelming, and the nineteen associate editors have, not unnaturally, had different views on the matter. The critical reviewer can find here and there examples of what he may consider as superfluities and inadequacies, but he must admit that neither his own, nor perhaps any, selection would be likely to meet with universal and unqualified acceptance. It can be said, and said cordially, that "Merriman" in its fifth edition maintains the high standard of previous issues and should have the same popularity; though, as affects British engineers, in quite a number of respects its outlook is definitely coloured by American conditions and American methods of practice.

B. C.

Aquatic Mammals: their Adaptations to Life in the Water. By A. Brazier Howell. Pp. xii + 338. (Springfield, Ill., and Baltimore, Md.: Charles C. Thomas; London: Baillière, Tindall and Cox, 1930.) 22*s.* 6*d.* net.

WHALES are fashionable at present, both among scientific men and the public, on account of their supposed forthcoming extinction by large steam whalers working upon the high seas away from all territorial control. A comparative anatomy of aquatic mammals based mainly on them, the sea cows, the seals, and the otters is hence opportune. Thirty-five other genera of aquatic mammals are mentioned, most being rodents or insectivores. The head with special sense organs, mouth, and skull come in for treatment, our author then passing to neck, trunk, tail, and limbs in turn. We feel that these chapters would be much more informative if the habits of aquatic animals had been reviewed at greater length, especially their food and feeding as closely affecting teeth and head. Theories are provided as to the fatty tissues, respiratory, digestive, and vascular systems, but we would have liked these studied more closely in relation to the author's Lamarckian views on evolution. Why he should state that "the porpoise has less need for intelligence than almost any other living mammal" is a mystery to us.

This book is necessary to libraries and will be useful to anatomists, for they will find in every section theories with which they disagree. They are possible explanations inserted by the author to stimulate his readers, and they are successful. He himself is only wedded to his Lamarckism as his introduction shows. We do not know how variations that can be selected by Nature arise, but we would like to know what percentage of each generation of his white mice "made to dig industriously in the ground for each and every day", with outcome a race with specialised digging feet, have died because they could not stand our author's drastic compulsion through "twenty or a hundred thousand generations". However, the functioning of all organs is the important study here, not the method of an evolution, which might just as well have been assumed.

The Passion for Life. By Rev. John Lewis. (Published on the Foundation established in Memory of James Wesley Cooper of the Class of 1865, Yale College.) Pp. x + 123. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1928.) 9*s.* net.

THESE five lectures have a certain interest as illustrating the contemporary tendency to strengthen older feelings and institutions by an infusion of science. Mr. Lewis is a student and a tutor of anthropology and also minister in a Welsh church. The last generation tended to shut the door of the laboratory when it went to the oratory: this one, including Mr. Lewis, tries rather to make passages between them. It is a wholesome change, but difficult to carry out, and liable to deform one or other of the structures thus connected. In this case the account of religion which results would not satisfy the more thoroughgoing students of religion. Mr. Lewis tells us that he is more and more convinced that the "premier motive of religion is the passion for life", but this definition, though containing a large element of truth, is both too wide and too narrow. The 'passion for life', being a general animal, or even biological, characteristic, can scarcely be taken as the differentia of the religious impulse in man, while, on

the other hand, the study of religion reveals other, perhaps equally potent, elements in its genesis—fear, for example, awe, and, above all, the social nexus, which, though cognate, cannot be identified with 'the passion for life'.

The book, however, contains a good deal of suggestive matter, rather of the hortatory than the scientific kind, and an interesting and more detailed account of the cult of the 'Great Mother', especially among the Babylonians. Mr. Lewis ranks first the Sumerian-Babylonian stage of civilisation, then the Egyptian, Indian, and Chinese, followed by Greece and Rome, the Arabian, the Mayan, and the British-American. F. S. M.

A Text Book of Dairy Chemistry, Theoretical and Practical: for Students of Agriculture and Dairying. By Edgar R. Ling. Pp. vii + 213. (London: Chapman and Hall, Ltd., 1930.) 6*s*. net.

THIS book is divided into two main parts—theoretical and practical. The theoretical part evidences very careful preparation and an appreciation of modern views in dairy science. In almost every section recent investigations are referred to, and at the end of each chapter there are references to the publications cited.

The chapter on the constituents of milk contains a short account of the vitamins and of the part they play in nutrition. Chapter ii. deals with the composition of milk, and the factors which influence composition. In the following chapter attention is directed to the physiological and legal considerations which are associated with variation in composition, and reference is made to abnormal milk and the applicability of methods used for the detection of adulteration.

Milk products, condensed milk, dried milk, and cream are discussed, and in the same chapter are sections treating of the rising of cream, mechanical separation, reconstituted cream, etc. The conditions affecting the making of butter and the methods used in the detection of adulteration are referred to in Chapter v., whilst cheese and dairy by-products are dealt with in the following chapter. Mention should be made of the chapter on the action of heat on milk and the action of milk on metals. The treatment throughout the theoretical part is uniformly good; the subject matter is quite up-to-date and is presented attractively.

The second part deals with the practical operations used in the separation and examination of milk, and the methods of analysis of milk and milk products. Naturally there is not in this part the same opportunity for the exercise of individuality, but the details are fully and clearly given.

The Quantitative Analysis of Inorganic Materials. By Norman Hackney. Pp. xv + 378. (London: Charles Griffin and Co., Ltd., 1930.) 30*s*. net.

THE aim of the book, which is largely fulfilled, is to give sound, practical, and commercially accurate methods of analysis in a form suitable for use by advanced university students and graduates. Included in the scope of the work are sections dealing with the use of apparatus, the theoretical considerations underlying the more important analytical operations, the determination of the commoner elements, volumetric analysis, the more commercially important separations of the elements referred to, and the complete analysis of ferrous and non-ferrous alloys, and of a few selected ores and other materials.

The separation and determination of the metals are given in the order in which they are met when the analysis is carried out according to the usual group method, and are fully and clearly described, volumetric methods being given due emphasis. The importance of the application of most, though not all, of the newer organic reagents in the separation and determination of the elements is rightly stressed.

The book is free from printing errors and has a satisfactory index. In view of the recommendation of the Joint Committee for the Standardisation of Scientific Glassware, that standard volumetric glassware shall be graduated in terms of the litre (l.) and millilitre (ml.), it is undesirable to perpetuate the use of the symbol 'c.c.'. On the whole, however, the book can be recommended for use by students and young chemists in commercial laboratories. A. G. F.

Einführung in die theoretische Physik: mit besonderer Berücksichtigung ihrer modernen Probleme. Von Prof. Arthur Haas. Band 1. Fünfte und sechste, abermals völlig umgearbeitete und wesentlich vermehrte Auflage. Pp. x + 396. (Berlin und Leipzig: Walter de Gruyter und Co., 1930.) 15 gold marks.

THE new edition of the first volume of Prof. Haas's summary of mechanics and physics contains so many alterations that it is almost a new book. The main change, however, is the inclusion of two chapters on classical thermodynamics, the first on general principles and the second on their applications. In these chapters, as elsewhere, exact formulation of fundamental ideas and typical results is insisted upon rather than detailed analysis of specific problems, the general standard being rather above that of most honours courses in physics. Other important changes are additions to the section on generalised equations of motion, and the insertion of a section on diffraction. As a coherent account of classical work, this book, which is in the clear and precise style characteristic of all Prof. Haas's publications, is invaluable; it is to be hoped that the appearance of a new edition of the second volume, on more recent work, will not be unduly delayed.

Birth Control: Why and How. By George Whitehead. Pp. iii + 174. (London: John Bale, Sons and Danielsson, Ltd., 1929.) 6*s*. net.

MR. G. WHITEHEAD gives us a trenchant account of the arguments in favour of limiting the size of families, and also gives us an account of the mechanisms thereof. The author rightly points out that most of the arguments against birth control are based on sheer ignorance and prejudice, or the use of the subject for political propaganda.

Letters to the Editor.

Giant English Oysters (*O. edulis*).

IT is commonly believed that old individuals of *O. edulis* are incapable of spawning as females, and as the matter is of some importance economically, an interest is thereby added to the following observations.

On Sept. 20, 1929, Miss E. T. Nicol and Mr. W. Searle each collected a giant oyster (*O. edulis*) near low water mark on muddy gravelly ground in Salcombe Estuary, near the Salstone (east of the Salstone and south of Wareham Point). These oysters were kindly given to one of us (J. H. O.) for examination, and were kept in dishes in the hope that natural spawning might occur. Apart from size, these individuals were in all macroscopic respects similar to the common oyster (*O. edulis*). On Sept. 26, as spawning had not occurred, and observations could not be continued after the following day, the oysters were measured and weighed, and then placed in a strong solution of T.N.T. (trinitrotoluene) to narcotise them. On Sept. 28 the oysters were not sufficiently narcotised to permit careful opening, but Mr. Amirthalingam arrived at the laboratory and continued the observations on the living animal. The oysters were carefully extracted on Sept. 30 and both were found to be females. The larger oyster, *B*, had in fact spawned a few ripe eggs into the mantle cavity and was found to be a very fine well-fished individual with its gonad and gonoducts full of ripe eggs ready to be spawned. The eggs are of the same size, *c.* 150μ,

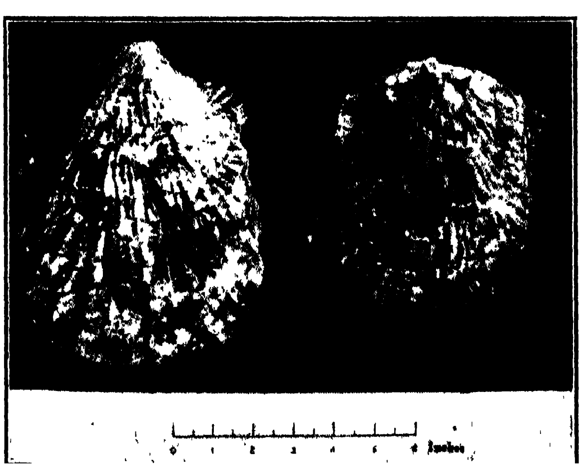

FIG. 1.—Giant oysters from Salcombe Estuary.

as those in smaller *O. edulis*. The smaller individual, *A*, was a well-fished maturing female and contained developing eggs 80-100μ in diameter. The gonoducts were empty.

The flesh of each oyster was rough dried with blotting-paper and weighed: *A* weighed 67 gm., and *B* 94 gm. As a fine oyster meat weighs only 8-8½ gm. these weights offer a good criterion of size. The entire giant oysters weighed respectively 731 gm. (= about 1⅝ lb.) and 1265 gm. (= about 2¾ lb.), and their shells were very 'deep' as well as large (see Fig. 1). A large entire eating-oyster weighs 2-2½ oz. and has a subcircular shell 8-9 cm. in diameter and depth about 3 cm. The shell *A* had the dimensions: Length and breadth, each = 15·8 cm., and depth = width = 4·3 cm.; *B* had length = 17·6 cm., breadth = 19·8 cm., and depth = 5·9 cm., as shown with other dimensions in Table I. Both individuals were therefore undoubtedly giants, and not merely large thin specimens such as are sometimes produced from a flat habit of growth—as on a flat surface of attachment.

Similar giants have occurred in other localities. On June 4, 1927, one of us (J. H. O.) examined a sample of 17 large deep oysters (4-4½ inches subcircular) originating from Poole Harbour. These observations were made at the beginning of the breeding season, when four individuals were found to be ripe or nearly ripe females, seven ripe or nearly ripe males, two others indifferent males and four individuals in a neuter condition. Similar large individuals are said to have been common at one time in the upper reaches of the Fal River, and fossil forms of apparently the same species are known to attain a length of about 10 inches.

TABLE OF DIMENSIONS OF GIANT SALCOMBE OYSTERS (*O. edulis*).

	Length in cm.	Breadth in cm.	Width in cm.		Weight entire (gm.).	Weight of Dry Shell (gm.).	Weight Oyster Meat (gm.).	Approx. Wgt. of Liquor (gm.).	Approx. Vol. of Liquor (c.c.).	Sex.
			External.	Internal.						
A	15 8	15·8	4·3	3·0	731	574	67	70	68	Maturing female
B	17·6	19 8	5·9	3·8	1265	1038	94	133	130	Ripe female

It is difficult to estimate the ages of specimens *A* and *B* owing to the possibility of two increments of shell occurring in one season, but it is certain that the age would be expressed in double figures. The observations recorded above, however, show clearly that large or giant oysters do retain the capacity to function as females. From what is now known about *O. edulis*, there is therefore every probability that individuals may change sex annually from female to male and back again to female from the age of about three to at least twelve years, if left undisturbed on good oyster beds. There is also little doubt that the oyster *B*, mentioned above, would have produced at least 10 c.c. and possibly 20 c.c. of eggs, which if developed would have yielded a minimum of about three million larvæ. Hence the value of large oysters of this kind not only for adding to the stock on good beds, but also for replenishing those beds which have apparently been fished out. It is indeed possible that the sudden repopulating of old beds may be due to a spatfall obtained under favourable conditions from relatively few giant individuals tucked away in inaccessible places. The shells of *A* and *B* are retained in the museum of the Marine Biological Laboratory at Plymouth.

Measurement of Space-Potential in High Frequency Discharge.

MEASUREMENTS of the space potential as well as the concentration and the average velocity of the ions and electrons in the different parts of a discharge tube have been greatly facilitated by the elegant method developed by Langmuir and Mott-Smith (*Phys. Rev.* 28, p. 727; 1926). This method has already been

successfully employed in the study of d.c. discharges, but, so far as we are aware, it has not yet been used in a.c. discharges. In the latter case, a number of difficulties have to be overcome before it can be successfully applied.

In dealing with d.c. discharge, the space-potential is generally referred to that of one of the electrodes maintaining the discharge; it cannot be so referred in the case of an a.c. discharge. Moreover, in high frequency discharges obtained with external sleeve electrodes—a subject of many recent investigations—the volt-ampere characteristic of the Langmuir 'exploring electrode' cannot be obtained when one of the external electrodes is used in the circuit.

We have been able to overcome this difficulty by using an extra bobbin-shaped internal electrode to complete the circuit through the 'exploring electrode'. This internal electrode is kept outside the region of the main discharge so as not to affect it in any way. A typical volt-ampere characteristic as obtained by us in oxygen at a pressure of 0·14 mm. of mercury is plotted in Fig. 1 with the logarithm of the current to the 'exploring electrode' as ordinate and its voltage as abscissa. It is to be observed that the nature of the curve is similar to that obtained in d.c. discharges as described and fully discussed in "Conduction of Electricity through Gases" (Methuen's Monograph Series) by K. G. Emeléus.

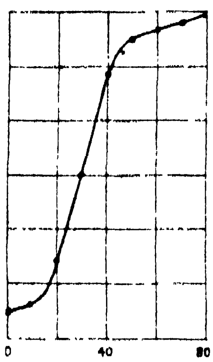

FIG. 1.—Characteristic log I, V curve.

From such characteristic curves we have measured not only the variation of the space-potential but also the concentration and the average velocity of the electrons in different parts of the discharge. A typical set of results is given below:

Oxygen under pressure 0·14 mm. of Hg.
Distance between electrodes, 15 cm.
Frequency, $1{\cdot}2 \times 10^6$.

Distance from left electrode.	Space potential.	Average electron velocity (volts per cm.).	Concentration of electrons.
4·5 cm.	24 volts	7·83	$2{\cdot}62 \times 10^8$ per c.c.

A detailed description of the method with discussion of the results is being published elsewhere.

Incidentally, it may be mentioned that C. J. Brasefield (*Phys. Rev.* 35; 1930) has carried out measurements of electron velocities in high frequency discharge by a spectroscopic method, remarking that it is extremely difficult, if not impossible, to employ Langmuir's 'exploring electrode' method for measurements in high frequency discharge. The above application of Langmuir's method, the success of which is evidenced by the agreement of some of Brasefield's results with ours, was developed by us before Brasefield's paper came to our notice and shows that his remark regarding the difficulties apprehended, but not specifically mentioned in the paper, is not warranted.

The Possibility of Separating Two Forms of the Ammonia Molecule.

A FEW years ago it was observed by Baly and Duncan (*Jour. Chem. Soc.*, **121**, 1008; 1922) that ammonia gas drawn quickly from a cylinder containing liquid ammonia was less rapidly decomposed on a hot platinum wire than gas drawn slowly from the same cylinder, or obtained in certain other ways. They offered as a possible explanation that ammonia molecules may exist in two forms of different reactivity, which may be separated or perhaps converted entirely into one form under suitable conditions.

Since that time, spectroscopic evidence has indicated the existence of two, or perhaps several, kinds of ammonia gas molecule, which presumably differ in certain symmetry properties, and it has been suggested by Tronstadt (*Z. f. Phys. Ch.*, Abt. B, **5**, 355; 1929) that a separation of such forms may have been achieved by Baly and Duncan.

Although this explanation of the different decomposition rates observed by these experimenters seemed to me rather improbable, it would be a very important fact if such a separation can occur under the conditions of ordinary chemical experiments, especially if the forms separated should have appreciably different reactivities. Consequently the question has been put to a spectroscopic test by a study of three of the absorption bands of ammonia gas in the red and near infra-red, making comparisons on gas obtained under varying conditions. The bands chosen were those at 8800 A., 7920 A., and 6474 A., which have been analysed by Badger and Mecke (*Z. f. Phys. Ch.*, Abt. B, **5**, 333; 1929) and Badger (*Phys. Rev.*, **35**, 1038; 1930). Though they are perhaps not yet understood in all their finer details, it seems quite certain that all these bands give evidence for two forms of ammonia molecule.

In the case of the bands at 8800 A. and 6474 A., ammonia gas drawn rapidly from a cylinder (a 10-litre vessel was filled in 3 sec.) was compared with gas drawn slowly from the same cylinder, and with gas which had stood five days in the absorption vessel. In the case of the band at 7920 A. a similar comparison was made, and in addition a sample of liquid ammonia was fractionated and the gas obtained from the first and last fourths was compared. The gas evaporated from solid ammonia which had been kept at liquid air temperature twenty-four hours was also studied.

In every case the same absorption spectrum was obtained. Neither the intensity of the bands as a whole nor the relative intensities of the various band lines was appreciably different from the usual in the case of any of the gas samples.

Consequently it is very unlikely that the results of Baly and Duncan are to be explained by a separation of two forms of ammonia molecule, or that such a separation occurs under ordinary experimental conditions.

Isomorphism and Chemical Homology.

THE ions of the formula AX_4 (for example, SiO_4, CrO_4, etc.) have been studied, and their fundamental vibration frequencies can be accounted for by simple molecular models: the polarisability of the oxygen ion in all these cases where it enters is of the same order as that given by the refraction of the crystalline oxides. It is admitted that in these cases the linkages are ionic.

Now, considering the ionic radii of the following as given by Goldschmidt and Pauling :

$\overset{++}{Be} = 0·34A.$	$\overset{+}{NH_4} = 1·43A.$	$\overset{+++}{B} = 0·20A.$	$\overset{++++}{Ti} = 0·64A.$
$\overset{++++++}{S} = 0·34A.$	$\overset{+}{Tl} = 1·43A.$	$\overset{+++++++}{Cl} = 0·26A.$	$\overset{+++++}{Nb} = 0·69A.$
$\overset{+++++}{P} = 0·35A.$	$\overset{--}{O} = 1·32A.$	$\overset{++++}{Th} = 1·10A.$	$\overset{++++++}{Mo} = 0·62A.$
	$\overset{-}{F} = 1·33A.$	$\overset{++++}{U} = 1·05A.$	$\overset{++++}{V} = 0·61A.$

predictions of certain cases of chemical analogy and isomorphism are possible.

For example : $\begin{cases} \overline{\overline{BeF_4}} & BF_4 & [\overset{IV}{Ti}F_6]^{--} \\ SO_4 & ClO_4 & [NbOF_5] \\ & SO_3\overline{F} & [\overset{VI}{Mo}O_2F_4] \end{cases}$ $\longrightarrow$ observed by (Magignac).

$\left.\begin{matrix} [\overset{VI}{Mo}O_2F_4] \\ [\overset{V}{Mo}OF_5]^{--} \end{matrix}\right\}$ Mauro and Scacchi (*Rend. R. Accad. Lincei*, 1888). $\begin{cases} [\overset{V}{V}O_2F_4]^{---} \\ [\overset{IV}{V}OF_5]^{---} \end{cases}$

For the realisation of these predictions, other factors such as the deformability of the constituent negative ions must be considered. The easiest way is to see whether the molecular volumes of the simple salts of the corresponding complex ions are sufficiently close (isomorphic tolerance being of the order of 10 per cent) and then whether they form mixed crystals in all proportions. Once assured of this, it is possible to extend the predictions to more complex cases. Search of the literature shows that in recent years similar examples have been observed by Wilke-Dörfurt and Günther Balz (*Z. Anorg. Chem*, **159**, 197 ; 1927) in the cases of $\overline{BF_4}$, (SO_3F) , and $\overline{ClO_4}$ ions. All simple and complex salts of the corresponding ions are isomorphous.

In continuation of his work on the homology of fluoroberyllates and sulphates, Dr. P. B. Sarkar has recently obtained further interesting examples of chemical analogy and isomorphism of the monofluorophosphate ion (PO_3F) with the SO_4 ion. Both SO_4 and PO_3F ions are likewise isosteric and isoelectric. Having determined the molecular volumes of K_2SO_4 and K_2PO_3F, which are very close, he found that they formed mixed crystals in all proportions.

Working on this analogy, he has been able to isolate the following compounds :

Series (i) MSO_4, $(NH_4)_2PO_3F$, $6H_2O$
where M = Ni, Cu, Co, Zn, Mn, and Mg.

Series (ii) $NiPO_3F$, $(NH_4)_2PO_3F$, $6H_2O$
$CoPO_3F$, $(NH_4)_2PO_3F$, $6H_2O$ } isomorphous with the double sulphates of Locke.

Series (iii) $NiPO_3F$, $7H_2O$ isomorphous with $NiSO_4$, $7H_2O$
$CuPO_3F$, $5H_2O$ „ „ $CuSO_4$, $5H_2O$
$CoPO_3F$, $6H_2O$ „ „ $CoSO_4$, $6H_2O$

Series (iv) Am_2PO_3F, $Al_2(SO_4)_3$, $24H_2O$
Am_2PO_3F, $Al_2(PO_3F)_3$, $24H_2O$ } isomorphous with alums.

Thus a close chemical analogy of ions composed of elements belonging to widely different groups of the Periodic Table is possible.

A detailed study of these will be published in the *Journal of the Indian Chemical Society*.

Spike Disease of Sandalwood.

IN NATURE of June 14 a short account is given of the work on spike disease of sandalwood in progress in the Biochemical Department of the Indian Institute of Science, Bangalore. This disease had previously been investigated in the laboratories of the Mysore Agricultural Department under the direction of Dr. Coleman, whose transmission experiments indicated the probability of a virus infection. In view of the very extensive damage caused by the disease not only in Mysore State but also in the Madras Presidency and Coorg, proposals were considered for a joint investigation by Mysore, Madras, and Coorg. For various reasons the Mysore Government preferred to continue on independent lines, but arrangements were made by the Government of Madras and the Administration of Coorg for an investigation to be carried out at the Indian Institute of Science under my general direction. Under this scheme the two authorities named have made an annual grant for the employment of a special staff which has enabled two whole-time assistants to be employed on this research, assisted by various research students in the Department. At the same time facilities were granted for extensive field experiments to be carried out in the Salem district of Madras and in Coorg with the co-operation of the forest officers concerned. In these circumstances it has been possible to arrange for an investigation of wide scope both in the laboratory and in the field.

Results of very considerable interest have already been obtained not only in the comparative study of diseased and healthy sandal but also in regard to the transmission of the disease. The view put forward by Dr. Coleman as to the infectious nature of the disease has been fully confirmed, and by an improved technique the disease can now readily be transmitted by bud or patch grafting, by the latter term being meant the simple implantation of a small patch of stem tissue from a diseased specimen in the stem of a healthy plant. The success of this method has much facilitated the inquiry by rendering available for study plants of various ages in all stages of the disease, grown under controlled laboratory conditions.

Sandal is of course a parasite, and the inquiry has already demonstrated that the nature of the host plant probably exerts a considerable influence on the susceptibility of sandal to infection. There is in evidence a marked variation in susceptibility, and it seems likely that a study of the factors responsible for such variation may open up an important line of advance in the practical amelioration of the disease.

Shortly before I left Bangalore in August last, arrangements were put in hand for a further entomological survey of sandal areas in view of the possibility of an insect vector being concerned, the circumstances in which the disease spreads lending considerable support to such a theory. It is understood that such a survey will shortly be undertaken.

Control of Mites Attacking Stocks of Insects and Fungous Cultures.

MITES have long been a great hindrance to the experimental entomologist and mycologist. Successful efforts have recently been made at the Imperial College Biological Field Station to kill mites and their eggs by fumigation, without harming to any considerable extent insects or fungi.

Pyridine and ammonia, recommended by Jewson

and Tattersfield (*Ann. Appl. Biol.*, 9, 213; 1922), for removal of mites from fungous cultures, were found to be harmful to insects and to their food. Pure acetylene, shown to be harmless to the larvæ of *Plodia interpunctella* Hb., although toxic to the adults of *Ephestia kuhniella* Zell., unfortunately proved to be harmless to mites at any concentration. Finally it was decided to try carbon tetrachloride and trichlorethylene, since both compounds have most of the properties desirable in a fumigant but are effective against the more resistant stages of most insects only at high concentrations.

At ordinary room temperature and humidity, exposure of infested cultures of the following groups of *Aspergillus*, *flavus*, *fumigatus*, *tamarii*, *terrens* and *niger* and of a species of *Syncephalastrum*, to carbon tetrachloride at a concentration of 0·5 c.c./litre for twenty-four hours, killed the mites but left the fungi unharmed. Exposure to trichlorethylene for the same time but at half the concentration gave the same result. Fumigation of infested stocks of *Calandra granaria* L. in barley and maize, and of stocks of *Rhizopertha dominica* F. in maize, with carbon tetrachloride at a concentration of 0·5 c.c./litre for four hours killed the mites while, after thorough aeration, the bulk of the adult insects recovered.

Trichlorethylene used at a concentration of 0·225 c.c./litre for twenty-four hours for the fumigation of stocks of *Calandra granaria* and of *Sitotroga cerealella* Ol. in barley freed the stocks of mites while allowing a useful percentage of the insects to survive.

Experiments with these insects in tubes when removed from their food have shown that:

(1) Adult beetles survive the fumigation; (2) moths and eggs of *Sitotroga* are killed but the larvæ and pupæ survive; (3) adult mites are killed by exposure to carbon tetrachloride at a concentration of 0·35 c.c./litre for only four hours or to trichlorethylene at a concentration of 0·225 c.c./litre for the same time; (4) eggs of mites are killed by exposure to trichlorethylene at the concentration of 0·225 c.c./litre for twenty-four hours.

Determination of the mites used is not yet completed.

Further details together with the results of fumigation of other insects will be published shortly.

Sunspots and Pressure Distribution in Monsoon Regions.

THE excellent collection of "World Weather Records" affords an opportunity to examine the mutual relation between the sunspot period and air pressure distribution over the globe. This relation I have studied by computing the difference between mean annual air pressure (for three years) near sunspot minimum and that for the following maximum. This difference I call 'effect', as does Dr. Mecking, who introduced this expression (*Annalen der Hydrographie und maritimen Meteorologie*, 1918). I have used all pressure material published in the above-mentioned collection, computed the differences for years: 1911-13-1917-19; 1900-02-1905-07; 1888-1890-1892-94; 1877-79-1882-84; 1866-68-1870-72; 1855-57-1859-61; 1842-44-1847-49; and so far as it was possible, plotted charts showing lines of zero effect separating the areas of positive and negative effect. These charts show slight differences from one sunspot period to another; a discussion of them will be published elsewhere.

While drawing the charts, the question arose whether there is on the earth an area where the air pressure effect is related always in the same way to increasing spottedness, that is, where on the earth is increase of sun spottedness associated always with an increase or always a decrease of air pressure (annual mean for three years)? The charts have shown that such an area of positive effect actually exists and it covers roughly the following regions: The first area is Central Asia about south of latitude 55° N., east of Caspian Sea, Mesopotamia, Persia, Afghanistan, Baluchistan, east Turkestan, plains of the Indus. The second area lies north of latitude 10° and extends from the Arabian Sea across south-east India, Bay of Bengal to Burma and Siam, and the third area embraces nearly the whole of Australia, Java, and extends probably across the Indian Ocean to southern Madagascar and Natal.

These three fields cover approximately the greater part of the Indian monsoon area within the tropics. The fact that the sunspot period manifests itself always in the same way within this area suggests that sunspots affect the general circulation of the atmosphere through pressure conditions in the monsoon regions. Further discussion of the data computed for the successive months of the year will show how far this conjecture is justified. The area where the effect of the sunspot period is always negative was difficult to determine; examination of the maps seems to point to the fact that if there is any place it lies probably in a long strip across the Pacific, north of the equator and south of the latitude of Hawaii.

Oviparity in a Sea-Snake (*Laticauda colubrina*).

IN view of the fact that all sea-snakes (*Hydrophiidae*) are generally regarded as viviparous,[1] the following occurrence seems worthy of note.

A few days ago six specimens of *Laticauda colubrina* were presented to the Raffles Museum, where they were put into a tank of sea-water.

On the morning of June 5 it was noticed that several eggs had been deposited overnight; the number appeared to be six, but owing to the cloudy nature of the water it was difficult to say with certainty. Two were removed for examination and the remainder left in the water. It will be interesting to observe if any of these eggs hatch out. It seems uncertain whether they would usually be laid on land or in the water. The former seems probable,[2] as oviparity is usually associated with a terrestrial habitat, and *Laticauda* is known to spend much of its time out of the water, its broad ventral shields adapting it to shore-going. It frequently climbs fishing-stakes, insinuating itself under the blanket of the tenant, the warmth of whose body it appears to appreciate. On the other hand the eggs have not the usual leathery shell of those of land reptiles, but are covered with a thick skin through which the yolk and germinal disc are visible. Possibly this skin will harden on exposure to the air.

Of the two eggs examined, one measures 80 mm. × 25 mm., the other 68 mm. × 27 mm. It was of course impossible to tell definitely which of the snakes was the parent, but it was probably the largest specimen, calculated as well over five feet in length.

Keepers from the various lighthouses in the vicinity of Singapore report that *Laticauda* becomes numerous at this time of the year. This might be interpreted as a shoreward migration for breeding purposes, but it would be curious to find such a habit in reptiles so essentially tropical in habitat, in an area which is

characterised by the absence of seasonal change; and where there are very few organisms, plant or animal, terrestrial or aquatic, with definite reproductive periods.

This evidence of oviparity seems to support the view that the Laticaudinæ are the most primitive of the sea-snakes, for although the ventral shields might be regarded as an advantageous redevelopment, the egg-laying habit can scarcely be viewed in the same light, and must therefore be regarded as a legacy from an ancestral terrestrial form.

NORMAN SMEDLEY.

Raffles Museum, Singapore,
June 5.

[1] Malcolm Smith ("Monograph of the Sea-Snakes", 1926, p. xlv) reiterates this statement of previous authors.

[2] Semper (quoted by Gadow: "Camb. Nat. Hist. Reptiles", p. 637) observed that the young of this species were born amongst the rocks on the shores of low islands, and guarded for some time by the female.

The Dissociation Theory of Solutions.

IN Dr. S. C. Bradford's letter on this subject in NATURE of Aug. 2, he says "that the vapour pressure of salt solutions is determined by the attractions, volumes and motions of the particles only". This statement is obviously what should obtain; for, given any three suitable physical properties, a fourth should, theoretically, be calculable from them. Hence hypotheses such as that of dissociation, or of association between solvent and solute, should only be introduced when other phenomena are contemplated.

Working on the assumption that three physical properties are sufficient and that the areas of solute and solvent are involved, I have found several formulæ connecting osmotic pressures (and therefore the ratio of the vapour pressures of solution and solvent) with the volumes, areas, and concentrations. Two of these, which embrace aqueous solutions of cane sugar α methyl glucoside and isodulcite, both at 0° C. and 30° C., give a constant, the extreme variations of which are about 5 per cent. These two (omitting, for simplicity, the temperature function which is within 10 per cent of unity) are:

$$(1)\ P\omega s_1^2 s_2^2/N\left\{\left(\frac{s_2}{s_1}\right)^{\frac{2}{3}}+\left(\frac{s_2}{s_1}\right)^{\frac{4}{3}}+\left(\frac{s_2}{s_1}\right)^{\frac{6}{3}}+\ \right\}=\text{constant}.$$

$$(2)\ P\omega^2/A\left(1-\tfrac{1}{2}A^{\frac{2}{3}}+\tfrac{1}{4}A^{\frac{4}{3}}\right)=\text{constant},$$

where P is the osmotic pressure, ω the specific volume of the solution, s_1 is the change in the volume of a large quantity of solution when 1 gram of solvent is withdrawn, s_2 is the corresponding volume for the solute, N is the number of gram molecules in 1000 grams of solvent. If c_2 and c_1 are the grams of solute and solvent, respectively, in 1 gram of solution, then $A=\frac{c_2 s_2}{c_1 s_1}\times\frac{M_\omega}{M_s}$ (where M_ω and M_s are the molecular weights of solvent and solute respectively).

I hope to publish elsewhere a fuller discussion than is possible in the columns of NATURE.

Photo-Electric Cells.

THE merit of a theory is so easily distinguished from the merit of a book in which it is adopted that we are not debarred, as authors, from asking "F. C. T." for the grounds of his "most serious" criticism of our volume on "Photo-electric Cells" reviewed in NATURE of July 19, p. 90. He says that the theory that photo-electrons are the free electrons of the metal is "not one which is generally accepted"; and "generally" must surely refer to the weight rather than to the number of opinions. But what authority can have greater weight than that of Sommerfeld, Fowler, Nordheim, and all who are developing with such success a theory of the metallic state? They take it for granted that the photo-electric effect is one of the interconnected properties characteristic of the metallic state, and that this state represents the presence of electrons free in Drude's original sense, because their kinetic energy is determined by the temperature and much greater than any potential energy they may derive from atomic fields. There are doubtless a few antiquarians still fumbling with ideas of the era before quantum mechanics; but it seems to us that the theory to which "F. C. T." objects is by now one of the commonplaces of modern physics.

NORMAN R. CAMPBELL.
DOROTHY RITCHIE.

Wembley, July 21.

THE wording I adopted was perhaps a little unfortunate, as it might imply that I regarded my criticism as a most serious one, whereas on the contrary I felt that of the few small criticisms that occurred to me, the only one worth mentioning was the point about the photo-electrons being only free electrons.

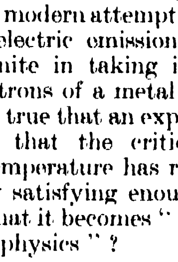
What I meant by the sentence to which the authors object, and what I still feel, is that, despite the success which has met the modern attempt to correlate thermionic and photo-electric emission, the authors were unjustifiably definite in taking it for granted that only the free electrons of a metal are emitted photoelectrically. It is true that an explanation of the very serious difficulty that the critical wave-length is independent of temperature has recently been given, but is that really satisfying enough to establish the theory so surely that it becomes "one of the commonplaces of modern physics"?

F. C. T.

The Formation of a Heterocyclic Ring containing Mercury Atoms.

IN an earlier paper (*Gazz. Chim. It.*, **58**, 712; 1928) I showed the possibility of obtaining some compounds probably containing a heterocyclic ring closed on mercury atoms, by the action of sodium thiosulphate on bimercuriated anilines.

In order to complete this series of investigations, I have treated *o*-dibromobenzene, in petroleum solution, in presence of acetic ester, with 2 per cent sodium amalgam, obtaining a crystalline substance to which I have been able to assign the following structural formula:



On boiling the substance with glacial acetic acid, it gives, by decomposition of the molecule, *o*. diacetylmercuribenzene and benzene.

The Ninth International Horticultural Congress.

THE long history and proud record of the Royal Horticultural Society is sufficient evidence that horticulture has long been highly regarded in Great Britain, and that British horticulturists have known how to organise themselves in the promotion of their common interests. Nevertheless, until the meeting of the International Horticultural Congress in London, on Aug. 7–15 last, as the result of an invitation delivered at the previous congress in Vienna in 1927, no international horticultural congress has previously met in Great Britain. Whilst the congress provides opportunity for the mutual discussion of problems which are often of great scientific interest and are presented at the formal sessions of the congress, these meetings, and the excursions with which they are interspersed, are perhaps still more valuable as providing opportunities for personal contact between workers, from many countries, interested in various phases of horticulture; at the same time the various committees set up and maintained by successive congresses give permanence to efforts to deal with such horticultural problems as the nomenclature of horticultural varieties and of the colours employed in their description, fruit culture, botanical gardens, the international exchange of young gardeners, etc.

At the dinner to the official delegates given by the Royal Horticultural Society in its Greycoat Street Hall on Monday, Aug. 11, very general expression was given to the opinion that this Ninth International Congress had been very successful and fully justified the hopes of the original promoters of this international horticultural effort. On its scientific side, horticulture is obviously very closely bound up with botany, and particularly with the study of the physiology and structure of the growing plant. The fact that the Fifth International Botanical Congress followed immediately at Cambridge (Aug. 16–23) naturally ensured a very representative attendance of foreign botanists, so that the three days devoted to communications upon horticultural topics showed a quite exceptional list of papers of great scientific interest. As a result, three sessions, devoted to papers, were conducted simultaneously in the Caxton Hall, the papers being grouped so far as possible around three main topics—propagation, pomology, and tropical and sub-tropical horticulture.

Some of the regular attendants at the International Horticultural Congress may have felt that their scientific colleagues' zeal had rather outrun their discretion. They certainly have a right to expect that, on these horticultural occasions, the botanist should make an effort to make himself intelligible. As always, at such conferences, the audience had occasionally to suffer from the inaudible lecturer; and also, sometimes, in view of the difficulty in darkening some of the large windows in one of the lecture halls, the lantern illustrations provided only intensified the obscurity of the lecturer's utterances. Communications might be made in one of three languages—English, French, or German—and this also added to the difficulty, as either speaker or audience might be struggling with an unfamiliar medium. International congresses, like our own British Association meetings, also suffer from the speaker who reads a paper which will be more suitably studied in print. In these days, when science has multiplied the facilities for intercommunication of ideas, there seems little excuse for this procedure. A halting speaker, or a speaker using an unfamiliar language, may well read from a manuscript, but at least that manuscript should be the condensed and vivid précis of the full account, intended for print, which an audience assembled at such pains has the right to expect. If the speaker on these occasions will not learn this lesson, then time will see all the business of these international meetings carried on in informal conversations in the corridors and anterooms around large empty lecture theatres.

Such a result would be unfortunate, because the papers presented are always, as in the present case, of very great interest. In the space available it is not possible to comment upon all communications. The main topic indicated in advance for discussion at the Ninth Congress, was propagation, vegetative and seminal. Many of the papers presented dealt with vegetative propagation, and in the following paragraphs an effort is made to indicate the general nature of some of the very interesting communications made under this head.

VEGETATIVE PROPAGATION.

The practice of vegetative propagation has always been of great interest, because by this means alone can most of the remarkable horticultural achievements obtained by hybridisation be perpetuated in the garden. It also appeals to the genuine gardener, because every new plant presents a new problem in practical propagation and new peculiarities of plant behaviour are always coming under notice in the propagating frames. Modern commercial methods now demand standardised horticultural produce, and this again sends the horticulturist to renewed study of vegetative propagation. A Cox's Orange apple can represent a definite standard of quality and flavour, because all Cox's Orange apples really come from one plant; the next generation is obviously going to see standardised types of cacao, rubber, coffee, tea, etc., driving others off the market, because they similarly will be the result of the successful development of vegetative propagation. Thus, in the present congress, Mr. W. G. Freeman discussed the vegetative propagation of cacao, Dr. P. J. S. Cramer and Lieut.-Col. F. Summers the propagation of rubber, whilst Prof. H. S. Reed communicated a paper by Prof. H. J. Webber, the Director of the Citrus Experiment Station at Riverside, California, upon propagation problems with citrus.

Some of the general considerations as to the development of vegetative propagation were raised

by Prof. J. H. Priestley and Dr. A. B. Stout. Vegetative propagation is a possible method of propagating the higher plant, because of its method of growth. The new parts of the plant are laid down at the apices of shoot and root respectively; therefore, when a plant is cut into pieces, provided it still contains such growing points or regenerates new ones, it will continue to grow. Many stems when cut from a bush thus grow on freely: a black-currant stem roots freely at its base, whilst the stem continues to grow and branch, so from one stem a new bush develops; from it again a stem can be taken and grown into a bush, and so many bushes can be obtained from one single bush—and thus in time one black-currant plant may occupy square miles of space and yield tons of crop, all the currants being as like to one another as the currants gathered from the original bush. There is still much discussion, which Dr. Stout ably summarised, as to whether such a bush can thus be multiplied not only indefinitely in space but also in time. The original bush would grow old and die, but there is no clear answer yet to the question whether the young bush, still being propagated from branches separated from bushes within this 'clone'—as the colony of vegetatively propagated plants from the same parent is termed—should necessarily fail in vigour with the increased age of the clone.

At one time 'degeneration' of such vegetatively propagated clones of potatoes was much under discussion; now it has been shown that such variation is often the result of the accumulation of disease within the stock, especially virus disease. When a true seed is grown from such a stock, the fertilised egg is separated from the parent plant by a barrier wall which usually prevents transmission of the virus disease. Thus the new seedling starts unhampered by the virus, which is now found in new members of the clone from the beginning; the result is that the new seedling seems more vigorous than the 'degenerate' descendant of the clone. It is sometimes possible, however, to select bits of the clone to which the virus has not yet spread, and then, by multiplying the new pieces of the clone from the virus-free stock, it seems possible to get it back in all its pristine vigour. At least, such work, as also the cases of vegetatively propagated seedless bananas and breadfruit trees, etc., show how dangerous it would be to attempt to set a limit, at present, to the potentialities in vegetative methods of propagation.

At the same time it has its very striking limitations; Dr. Auchter, of the Department of Plant Industry, Washington, U.S.A., illustrated this very vividly in his account of recent American work on rooting cuttings of fruit trees, especially apple. Very few varieties of valuable scion apples can be propagated upon their own roots, because it is so difficult to get branches from these trees to root when removed and put in the soil. Dr. Auchter described some very interesting experiments of Dr. Gardner at Maryland, in which 100 per cent success had been obtained instead of the usual 1 per cent or 0 per cent, the branches having been previously bound with black tape near the base since growth commenced, and whilst still on the tree—curiously enough, in this experiment, the buds on these rooting shoots failed to grow out! Dr. Auchter also brought to light the very interesting fact that propagation of seedling apple trees by either stem or root cuttings can often be successfully accomplished, although the same methods are quite unsuccessful when tried with the same tree when it is several years old. Dr. Niels Esbjerg also described attempts to root scion apples in which some success had been met with; whilst Dr. H. A. A. van der Lek directed attention to the significance of the presence or pre-existence of root initials in favouring rooting. External conditions in rooting cuttings were especially considered in communications (by Miss Mary E. Reid and Dr. P. W. Zimmerman, from the Boyce Thompson Institute for Plant Research, Yonkers, U.S.A.); whilst the very considerable practical success obtained in cutting propagation at the Edinburgh Botanic Gardens was described and illustrated by Mr. L. B. Stewart.

In spite of the advance that is slowly being made in this difficult field, the difficulty in propagating many desirable woody plants as cuttings results in their appearance as 'scions', raised into the air upon the root systems of another plant with which they are in union through the process of budding or grafting.

Around the Mediterranean, these practices are still utilised in various forms with the olive and the vine, and were discussed very fully by Dr. Mameli Calvino (Italy), Prof. Dr. H. Faes (Switzerland), whilst Prof. Ravaz (Montpelier) argued again the much-discussed problem as to the relative influence of stock and scion upon one another. Prof. Ravaz concludes that there is no reciprocal influence of stock and scion upon one another in vines, the colour, shape, size, and flavour, etc., of the grapes varying as much in a clone upon its own roots as when carried on various stocks. The general question at issue here is of great complexity and magnitude, and it is well worth while multiplying efforts to obtain scion varieties upon their own roots, as urged by Dr. Esbjerg, so that the performance of such plants may be compared with the performance of the varieties upon different stocks in the critical atmosphere of the experiment station. Where this is not possible, then the experiment station, following the lead of East Malling, will certainly try to study the performance of a clone of scion upon a uniform clone of vegetatively propagated stock, rather than upon different seedlings with, of course, varying growth vigour.

It is another question, however, and one keenly debated in horticultural circles now, whether the commercial propagation of seedling stocks should be replaced entirely by the vegetative propagation of stocks. In the United States, as in the British Dominions, orchards of root acreage have sprung into being within the last few decades, in which the scions have been budded or grafted upon seedling stocks because of the relative simplicity of this

method. On one hand, it is argued that it is not sufficient for horticultural standardisation, which has to meet stringent modern commercial requirements, that the scion should be a clone, so that the produce of one variety, whilst plucked from the branches of one and the same plant, may be nourished on those branches through the roots of countless different varieties. On the other hand, it is argued by the practical man, in the light of horticultural experience, that a Cox's Orange scion gives a Cox's Orange apple whatever the root system may be, and Prof. Ravaz's experience with vines seems to endorse this conclusion.

Whilst it is agreed that certain stocks, 'dwarfing' stock, modify the habit of the tree in that they cause dwarfed growth and early bearing, there is no evidence that the quality of the scion fruit is modified; and provided that ordinary care to select vigorous seedlings is shown, there seems little doubt that uniform orchards of the scions are obtained—uniform because the stock is not limiting appreciably the natural vigorous full growth of the scion.

Much work still remains to be done upon this interesting problem; the interchange of comment and criticism at the congress is a good augury for the report of progress at a later congress, whilst some of the contributions show the interesting range of the problems. Thus, Prof. N. F. Hansen (Dakota, U.S.A.), Dr. L. Filewicz (Poland), and Dr. J. Smolak (Czechoslovakia) joined in a symposium upon fruit culture problems in regions where frost damage is frequent and severe. In the course of this discussion, Dr. Filewicz pointed out that certain apple trees which are susceptible to frost in central Poland resist the winter after top-grafting with a more hardy variety. Dr. Filewicz described some very remarkable experiments in keeping frost-injured trees alive and bearing by making new unions between shoots thrown up from the roots and buds on higher branches still capable of growth.

An Elizabethan Colony of Craftsmen.

By Dr. E. F. ARMSTRONG, F.R.S.

THOSE who walk the fells of the Lake District will not have failed to notice the abandoned copper workings which scar the hillsides in many places, notably at Manesty and elsewhere in Borrowdale, near Stair and at Goldscope in the adjacent Newlands Valley, at Grasmere, in the Vale of St. John, and in other localities. Whilst it is common knowledge that these represent ancient mines dating from the time of Elizabeth, only the few are aware how unique and interesting a historical story is attached to these visible relics of bygone days. It has relation to the formidable enterprise of bringing from Germany to the Keswick dales a little colony of workmen and experts in the mining and smelting of copper. It needs very little imagination and knowledge of the existing conditions in England at that time to picture the dales as then, surely very remote from medieval civilisation, particularly when it is remembered that the Lord Warden was watching the fords to hold back the Armstrongs and the Grahams but a few miles north of where the craftsmen in Borrowdale were to be engaged in their peaceful activities.

Though the enterprise was in the end a business failure, it left its impress on the district in numerous ways, as witnessed by many mixed marriages with the dalesfolk, by German words absorbed into the local dialect, by place names: the details of all these afford a fascinating study in local history. Far more important, however, in its ultimate effect on the prosperity and future of the district, must have been the spending there during the life of the venture of upwards of £100,000, and that at a time when money was worth several times what it is to-day. Although many of the fortunes made locally were lost for King Charles, this undoubtedly led to a development of the Lake country, both then and afterwards, quite out of proportion to its inaccessible and wild character, as well as to the provision and maintenance of routes and roads to Newcastle via Barnard Castle and to the south in advance of the times. Leland, whose "Itinerary" was written about the year 1545, calls Keswick a poor little market town. Elsewhere we read of the Lake country being almost *terra incognita* until the publication of the letters of Gray, the poet. It is a satisfaction to those who are fighting for the preservation of the natural beauty of the district to-day to remember that Gray's later letters, especially those from the Lakes in 1769, show before those of most others the rising sense of the picturesque in literature.

The known facts relating to the settlement compiled from local sources have been supplemented in an altogether unexpected manner by the discovery at Augsburg of the original account books of the German firm, Haug, Langnauer and Co., including twelve volumes of manuscript which are the actual journals written at Keswick and sent first to Hans Loner, the agent in London, and by him, after some added pages of balancing, to Germany. These have been rendered available by W. G. Collingwood in 1912 in a publication of the Cumberland and Westmorland Antiquarian and Archæological Society.

The value and interest of this find is very great when it is remembered that the earliest known English diaries come from the late sixteenth century and that some of them grew out of a punctilious habit of keeping accounts. More than the usual bald facts of the financial operations began to be added, and the entries became amplified, so that one finds in them as here the ancient day spread out before us in considerable detail.

The Company or Society of Mines Royal was founded in 1564, when an indenture was made between the Queen on one part and Thomas Thurland and Daniel Hechstetter on the other, to search, dig, try, roast, and melt all manner of mines and 'ures' of gold, silver, copper, and quicksilver in a number

of counties. The Queen was to have one-tenth of the precious metals and one-twentieth or 2*s.* per cwt. on the copper.

Hechstetter proceeded to form a company with a number of prominent shareholders, including Lords Burghley, Pembroke, Leicester, and Mountjoy. In 1566–67 parties of German workmen were brought from Schwatz to Keswick. A rich mine was very soon found at Newlands, on the manor of the Earl of Northumberland, in 1566—the Germans called this "Gottesgab", a name which locally became Goldscope. The Earl stopped the working after a time, claiming the sole right to the minerals. His suit against the Queen went before all the judges and barons of the Exchequer in 1568, when it was decided by a majority that as there was more gold and silver than copper and lead in these mines, the Queen was within her rights in claiming them. A strange miscarriage of justice this, and an early example of faulty analysis (!), particularly as it remained the leading case regarding Royal rights in mines until the time of William III.

Hechstetter's accounts were made up seven times a year; they enable us to picture almost every happening in the life of the colony. For example, in 1569 we find complete accounts, amounting in all to £21 9*s.*, for building the men's bathroom. Whereas the company bore the expenses and outlay, the men agreed to repay this afterwards out of club money and fines. At that time, apparently, the use of baths was frequent in Germany, both in private houses and in public baths: it is stated that the hot bath was used as an antidote to immoderate drinking. Wine for the colony was bought by the tun or cask and resold to the men at a price which made no profit; there are entries of its purchase at Newcastle, at Kendal, and at Cockermouth, in the last instance from Henry Fletcher, the well-known merchant who had entertained Mary Queen of Scots on her landing at Workington a few months earlier (May 15, 1568), when she fled to England after the defeat of her army at Glasgow.

The smelt houses were begun in the summer of 1566 at Brigham, on the Grete, half a mile from Keswick. Within a year, Thurland confessed that they were "more chargable than he had imagined", an experience which has been repeated by most inventors of new processes down to this day. Hechstetter persevered, however, and did well to create, in a country so barren of facilities, a cluster of workshops and machinery so famous as to make Camden at the end of the century write "not without admiration to those that behold it". Alas! The progress of actual smelting was accompanied by the devastation of the woods far and wide, local labour being used for this purpose, though skilled charcoal burners were imported from the Midlands. An attempt was made to form charcoal-burning stations in Ireland at a time when the opposition of the Earl of Northumberland made local supplies difficult.

There are items in the accounts of 1569 for the carriage of sea or stone coal from Cockermouth and from Workington, and a payment of 1*s.* 4*d.* for a man to watch for several nights over the coal at the smelting house for fear of it burning; this seems to have been their first practical introduction to mineral coal. One Anthony Dediman was promised £20 if he found coal mines near Keswick; there is an entry of £4 in hand and 3*s.* 4*d.* earnest money. No coal was found, but he spent a good deal in this fruitless search.

Although the first royal charter to dig coal in the Castle Fields was granted in 1239 by Henry III. to the freemen of Newcastle, and the coal trade became an important branch of commerce within fifty years, apparently it was not in general use in provincial towns until the reign of Charles I. These journals must be the first records of coal being worked in Cumberland, for it was not until a hundred years later that Whitehaven became a busy export centre, chiefly to Ireland and Scotland.

The mines, workshops, and houses were lit with tallow candles, but in November 1570 there is mention of a sample of train oil which soon afterwards was used in the mines. Although, according to Hakluyt, whale fishing began somewhat later than this date, it is known that a number of English ships were fishing off Iceland about this time. This is probably one of the first uses of the oil in England.

The original business of Haug and Co. was drapery, and at first they tried to sell silk and satin and other costly stuffs at Keswick, disposing of more than £400 worth.

The mines were worked to some extent by what is called 'tributing'; the miner chose his own place, hewed at his own pleasure, and was paid a percentage on the value of the ore he got. He paid for his own candles and tools. Apparently the earnings by this method were very uneven. The system survived to the end of the period of copper-mining at Coniston.

The details of one of Hechstetter's journeys with three others from Augsburg to London show how he travelled by cart from Speir to Mainz, hired a boat to Cologne, then a covered carriage to Antwerp, thence to Calais, how is not stated: across the water to Dover, which cost £2 6*s.*, horses to Gravesend, and from thence to London by boat. The customs at Dover extracted 16*s.* duty! The same paragraph contains the item "a poor German in charity 3*s.*".

In spite of the energy of Hechstetter and his associates, the enterprise did not prosper financially; we are told that, notwithstanding very considerable quantities of copper had been won, the difficulty of finding a market was accentuated in 1571 owing to the depression of trade in England during that year. There is a long and somewhat despairing letter from Langnauer in Augsburg to Loner in London, who in consequence approached the Queen, probably through Leicester, begging her very materially to increase the amount of copper ordered from the company.

A little later fresh impulse was given to the business by the addition of coppersmith's work, that is, the making of kettles, pots, and pans, for which skilled men were again imported from Germany. An artistic craft was thus very early introduced

into the dales, which to-day the school of industrial art is perpetuating.

In 1576, Loner left the business, but Hechstetter struggled on for a few years: the company was reconstructed by Thomas Smyth in 1580. His enterprise prospered for some years, mines being opened also in Cornwall and South Wales, but by 1597 the Keswick works were in difficulties again. A little later, in 1600, an inquiry into the condition of the northern mines showed that in thirty-six years, after paying £4500 to the Queen, £68,103 had been made by the sale of metal, and the expenses had been £104,700 plus a capital outlay of £27,000. Nearly all the money, found and lost by Augsburg and London merchants, had been lavished in the dales.

The smelt houses were destroyed at the Civil Wars, probably in 1648, and many of the miners slain.

Certain points in this very slight sketch of the colony in the dales are outstanding; one, the effect of the intermarriage of the Germans with the dalesfolk in promoting some of the energy and intelligence for which the 'old stocks' were remarkable, which together with the then large sums of money spent locally by the enterprise have had a far-reaching effect on its subsequent prosperity and development; the other, the close parallelism between the trials and tribulations, both technical and financial, in starting a new industry three hundred and fifty years ago and to-day. Very little profit in this respect seems to have been gained by experience; indeed, it appears axiomatic that the first venturers will not reap material rewards. Then, as now, we cannot withhold admiration from the German craftsmen for their willingness to try new ideas, new methods, with scientific thoroughness and exactitude.

Obituary.

Prof. H. H. Turner, F.R.S.

THE death of Prof. H. H. Turner occurred at Stockholm, where he was attending the meetings of the International Union of Geodesy and Geophysics. Just before the afternoon meeting on Saturday, Aug. 16, he fell forward on the table. His colleagues at first thought he had merely fainted, but the doctor who was called found that he had a severe attack of cerebral hæmorrhage and had him removed to the hospital. His wife was informed and she and her daughter went at once to Stockholm by aeroplane. He died on Wednesday, Aug. 20, without recovering consciousness.

Herbert Hall Turner was born at Leeds in 1861, and went to the Leeds Modern School and then to Clifton College. He obtained a Major Scholarship at Trinity College, Cambridge, was Second Wrangler in 1882 and second Smith's Prizeman in the following year. He became Chief Assistant at the Royal Observatory, Greenwich, in 1884, shortly before his election to a fellowship at Trinity. He soon became interested in the problems of fundamental astronomy and made researches on the $R-D$ discordance of the Greenwich transit circle. He elucidated but did not find a complete explanation of this still unsolved problem of the persistent difference between the zenith distances of stars from observations taken by reflection from mercury or directly. It is still in doubt to what extent this is due to flexure of the instrument, the differences of temperature in the observing room from that outside, and other instrumental causes. Turner made series of observations of the temperature in different parts of the room, and varied the conditions in which the observations were taken, taking the direct observation before that made by reflection.

A leading part was taken by Turner in a determination of the longitude of Montreal. This was determined in three links: Greenwich-Waterville, Waterville-Canso, Canso-Montreal. The difference of longitude Montreal-Washington being already known, the longitude of Washington was thus determined. The result obtained by this complicated series of connexions agreed closely with the direct determination found in recent years with the assistance of wireless signals. The difference of longitude Paris-Greenwich was twice determined conjointly with French astronomers. Here the results were not accordant, as in both series the French obtained a larger value than the English observers. Accordant results were not obtained until 1902.

Turner took part in a number of eclipse observations, and, like other astronomers, suffered from the vicissitudes of weather. At one of these expeditions, a brother-astronomer was seriously ill with fever. With characteristic kindness, Turner deliberately read the thermometer wrongly to the patient, and so cheered him that his temperature fell before the end of the visit. For the eclipse of 1896, in Japan, Turner introduced the use of the cœlostat. M. Lippmann had pointed out that a mirror turning on an axis in its own plane at half the speed of the earth's rotation and pointing to the pole gave a stationary image of the entire field. Turner realised the great convenience of this for photography of the sun at eclipses, and, with his friend Dr. Common, designed instruments which have served English observers in many subsequent eclipses. The weather was unfavourable in Japan in 1896, but Christie and Turner had good fortune in India in 1898, Newall and Turner in Algiers in 1900, and Turner and Bellamy in Egypt in 1905. He went to Paris for the eclipse of 1912 as a spectator, as the duration of totality was too short for serious observation; and at the eclipse which passed over England in 1927 he and Dr. Knox Shaw had only partially favourable weather at Southport.

Turner entered heartily into the scheme for the International Photographic Map of the sky inaugurated at Paris in the late 'eighties. Christie obtained one of the standard astrographic telescopes made by Sir Howard Grubb for Greenwich, Gill one for the Cape, Pritchard for the University

of Oxford, and others were obtained by the Australian observatories at Perth, Melbourne, and Sydney. In November 1893, Turner contributed to the Royal Astronomical Society a short and important paper on the method to be employed in the determination of the positions of the stars from the micrometric measures of the photographs, a method which has been generally adopted by astronomers. After the death of Pritchard in 1893, Turner was appointed to succeed him as Savilian professor of astronomy at Oxford, and carried out the part of the work allotted to Oxford with great energy. He took the line that the short exposure photographs, which would give the positions of some two million stars, should be measured and the rectangular co-ordinates of the star-images published promptly with such additional data as were necessary for the determination of the accurate positions of the stars. He urged this very strongly, and on the formation of the International Astronomical Union was, on the nomination of the first president, M. Baillaud, appointed chairman of the Committee dealing with the International Photographic Map of the Heavens. His efforts have brought the scheme much nearer completion than it would otherwise have been. After finishing the Oxford section, he measured photographs belonging to other observatories, and was largely instrumental in getting the observatory of the Nizam of Hyderabad to take up the photography and measurement of a zone allotted to an observatory which had later been unable to carry out the work. Among other interesting by-products of the work, Turner found that owing to curvature of the field, the photographs which were in critical focus at a distance of 30′ or 40′ showed far fewer stars at the centre of the field than at this distance.

Turner was a delightful popular exponent of astronomy, with a natural facility for speaking. He also wrote several popular works on astronomical subjects. His short and lively contributions to the *Observatory* magazine, "From an Oxford Notebook," were widely read and appreciated. Some of these consisted of amusing incidents or historical reminiscences interesting to astronomers. Others contained references to the current work and publications of other atronomers, with friendly criticism and appreciation.

On the death of his friend Prof. Milne, Turner took charge and largely extended the organisation which Milne had formed for the collection of seismographic records from all parts of the world. Milne-Shaw seismographs, comparatively inexpensive instruments devised by Milne, but improved greatly by Mr. Shaw of West Bromwich and manufactured by him, have been installed all over the world and the times of different phases of the shocks were reported to Turner at Oxford. As in the Astrographic Catalogue, he attached great importance to the prompt collection and publication of these data, which have thrown great light on the internal constitution of the earth. Turner made frequent harmonic analyses of earthquake records with the view of finding correlation between them and other astronomical and meteorological phenomena.

His disposition made Turner like work in co-operation with other people. He always enjoyed the international meetings of astronomers and other men of science. He invited the International Solar Union to Oxford in 1907, and attended the meetings at Meudon in 1904, at Mt. Wilson in 1910, and at Bonn in 1913. He was also a Royal Society representative at the meetings of the International Association of Academies. At the meetings of the International Astronomical Union he has been president of the Committee for the Photographic Map of the Heavens, and at the International Union of Geodesy and Geophysics, president of the Section of Seismology. He was secretary of the British Association from 1913 to 1922.

Turner will be greatly missed at the meetings of the Royal Astronomical Society, which he attended with the greatest regularity. He has served on the council for forty-three years, and has been secretary, president, and foreign secretary of the Society. At the council meetings he invariably took a charitable view of a doubtful paper, and at the meetings never failed to compliment a young author on his research. At the dining club after the meetings he was secretary and Glaisher president, to the great satisfaction of the members, for many years. On Glaisher's resignation owing to failing health, Turner became president, and continued to delight and enliven the gathering by speech and occasionally by song. He took a great interest in other people's work, including modern developments, and was a very kindly and genial colleague, whose death will be mourned by astronomers all over the world.

Prof. Turner was elected a fellow of the Royal Society in 1896. He was a corresponding member of the Paris Academy of Sciences, and he received the Bruce medal of the Astronomical Society of the Pacific in 1927. He was given honorary doctorates by the Universities of Leeds, Sydney, Wales, Strasbourg, Durham, and California. F. W. D.

PROF. J. F. POMPECKJ.

DR. JOSEF FELIX POMPECKJ, professor of geology and palæontology in the University of Berlin, and Geheimer Bergrat, died on July 8, while still in the midst of his activities. He was born in East Prussia on May 10, 1867, and graduated as Ph.D. at Königsberg in 1890, with a thesis on Trilobites. He had a varied official career, beginning in 1891 as assistant in the geological institute at Tübingen, and removing two years later to Munich, where he was both a curator in the Palæontological Museum and *privat-docent* in the University. In 1904 he became professor in the Agricultural Academy at Hohenheim, and in 1907 he was promoted to the professorship of geology first in the University of Königsberg and then in the University of Göttingen, where he followed A. von Koenen. He remained at Göttingen for six years, and in 1913 returned to Tübingen as professor in succession to E. Koken. In 1917, on the retirement of his old teacher, W. Branca, he was appointed professor in the University of Berlin, and in 1925–26 he served his term as rector of the University.

Prof. Pompeckj was especially insistent on the necessity of studying sedimentary rocks and fossils together, and all his researches were guided by this idea. In continuation of his doctoral thesis, he began by studying the Trilobites and other early Palæozoic fossils and their distribution in the various rocks in which they were found. He published papers on Trilobites and on the Cambrian formations of Bohemia, Sardinia, and other regions. In his latest years he returned to the same subject when examining the boulders on the north German plain. His most important work, however, was on the stratigraphy of the Jurassic formation, especially of Württemberg, but also of the Arctic regions, from which he examined several collections of rocks and fossils. In this connexion he became an authority on certain groups of Ammonites and other Mollusca. He was ever in search of general principles, and his addresses on the former extension of seas (1909), on race-persistence among Ammonites (1910), on the origin of the copper-slate (1920), and on environment, adaptation, and struggle in the light of geological research (1925), are full of interesting and valuable suggestions.

Outside the University, Prof. Pompeckj also took his full share in promoting geological and palæontological science. For many years he was one of the editors of the *Palaeontographica*, *Geologische und Paläontologische Abhandlungen*, and *Neues Jahrbuch für Mineralogie, etc.*, and he was an active member of the German Geological Society, of which he was several times president. The Geological Society of London expressed its appreciation of Prof. Pompeckj's contributions to science by electing him a foreign correspondent in 1925.

WE regret to announce the following deaths:

Dr. Henry Fraser, formerly director of the Institute for Medical Research, Federated Malay States, when he made valuable contributions to our knowledge of beri-beri, bacillary dysentery, and leprosy, on July 17, aged fifty-seven years.

Mrs. Albert Howard, Second Imperial Economic Botanist to the Government of India, who was associated with her husband in the work of the Institute of Plant Industry, Indore, on Aug. 18, aged fifty-three years.

His Grace the Duke of Northumberland, K.G., president of the Royal Institution and Chancellor of the University of Durham, on Aug. 23, aged fifty years.

Dr. George W. Patterson, associate dean of the College of Engineering of the University of Michigan, known for work on standards of electrical current, on May 22, aged sixty-six years.

Prof. Conrad von Seelhorst, professor of agriculture in the University of Göttingen, author of "Handbuch der Moorkultur", on July 6, aged seventy-seven years.

News and Views.

THE anniversary address of Mr. C. R. Peers, president of the Society of Antiquaries, which is printed in full in *The Antiquaries Journal* for July, ranged over a wide variety of topics in archæological research, not the least interesting section being his review of current activities in the field. A matter of special interest to the readers of NATURE, in view of recent correspondence in our columns, was the reference to the researches of Mr. Reid Moir and Mr. Burchell on the boulder clay of Norfolk and Yorkshire. Touching upon the archæological aspect of their work, he pointed out that in common with other recent research, it tended to contract still further the distinction which has been drawn between the culture of palæolithic and neolithic man. For these glacial deposits have been found to contain an appreciable number of flints which were surface deposits before the clay was laid down, and are, therefore, indubitably of palæolithic date, yet of a type which would generally be regarded without question as being neolithic. Such a classification, he said, can no longer be accepted, and palæolithic man would appear to have "made a most impressive invasion of what, till late, was neolithic territory".

IN dealing with research in the field, Mr. Peers referred in some detail to the conditions in which excavations are being carried out under the auspices of the Society of Antiquaries at Colchester and St. Albans. A preliminary account dealing with the first fortnight's work at St. Albans appeared in the *Manchester Guardian* of Aug. 14. The prospects are indeed promising. There are already indications that it may be possible to fix with some certainty the date of the great defensive Roman wall, assigned by some to the first, by others to the third century A.D. If further investigations confirm that it is of first century date, as the evidence at present suggests, it will also fix the date of the London wall, which is identical in construction with that at St. Albans, and in both cases will demonstrate the correctness of the view which holds that these cities were walled after the suppression of Boudicca's rebellion. The entrance gates of the town have been unearthed and the foundations of one of the two flanking towers usually found with such gates have been laid bare. Verulamium has a history stretching from prehistoric times to the fifth century A.D. This is unique in Britain, and with the view of throwing light on its Celtic culture and on the later phases in its history, Mrs. Wheeler is excavating houses fronting on Watling Street within the town. Three have now been unearthed. They show that after the Roman occupation the Roman art of building was lost, but a remarkable pot, unearthed from the beaten clay floor which had been laid down over the tesselated pavement, suggests that the Roman-taught art of pottery was still practised in degenerate form.

WE have received an interesting communication, unfortunately too long to print in full, from a correspondent, W. W. L., commenting upon the views expressed in our article "Education, Environment, and the Criminal" (NATURE, July 12, p. 45). The writer directs attention to the arguments and assumptions typified in that article, and urges that the attitude of science to-day countenances a self-expression demanded for unregulated and uncontrolled impulses

and selfish desires, while neglecting the means whereby the true individuality of man can evolve and find self-expression. Finally, our correspondent asks whether if human beings have no conscience, no psycho-spiritual nature, no evolutionary objective, does it matter what they do? W. W. L.'s letter raises a question which is becoming increasingly important in modern life, namely, the relation of science and ethics; but the form in which the criticism is made suggests an application of a moral standard as a test of the validity of scientific reasoning which would stultify research. The research worker as such, whatever his duty towards humanity and his fellow-citizens as an individual, in dealing with scientific data is concerned only with the truth—the facts, and the inferences from those facts. It is in the application of scientific conclusions to the problems of life that the ethical standard comes into operation. It is not for the psychologist or the sociologist to speak of the 'higher' and 'lower' impulses in the sense used by our correspondent. These are distinctions for the social reformer who applies the conclusions of the psychologist and the sociologist relating to these phenomena in dealing with his own special problems of social reform.

AN article by Prof. Raymond Dart, in the *Times* of Aug. 22, gives an account of some results obtained in excavating the Mumbwa Caves during the last three months by the Italian scientific expedition operating in Portuguese East Africa, South Africa, and Southern Rhodesia under Capt. Attilia Gatti and Prof. Lidio Cipriani. Mumbwa is approximately 130 miles south-west of Broken Hill, where Rhodesian man was discovered. The excavations revealed strata with implements ranging from the most recent types of stone age implements to Mousterian; but the most interesting find was that of a peculiar type of iron smelting furnace at a depth of six feet below the surface above it and eight feet below the surface at the middle of the cave. This is the first occasion on which a smelting furnace has been discovered in South Africa in conditions which permitted of an archæological dating. On one side of the furnace was a great accumulation, 2 ft.–3 ft. thick, of ashes, burnt rock, incinerated bones, clay, slag, and of quartz and metal showing the action of fire. On the other side, between the furnace and the cavern wall, were human burials. Two of these which were carefully excavated showed that the bodies were buried in sepulchres of stones piled beehive fashion and supported by earth. The skeletons were all of Bushmen. The furnace stratum and overlying earth were filled with quartz flakes and implements of middle and late stone age type, and one foot below the furnace was the Mousterian level with implements of ironstone similar to that which attracted the iron smelters. In the superficial deposits were found occasional iron arrow-heads and pottery, these probably of Bantu origin.

IT is obvious, in view of the peculiar archæological conditions in South Africa, that the material discovered by Capt. Gatti and Prof. Cipriani is susceptible of very diverse interpretation. Prof. Dart himself regards the furnace culture as coeval with the later phase of the palæolithic and as the introduction of a superior race into an Africa "still in the throes of the stone age". The continuation of the stone age culture relatively unaltered, he holds, shows that the local inhabitants were not initiated into the mysteries of the smelters. It is further suggested that this evidence points to an antiquity for a knowledge of iron smelting in Rhodesia of 3000–4000 years, the superficial supposedly Bantu finds being perhaps 2000 years later. Prof. Dart goes on to point out that whereas the Zimbabwe culture, usually associated with mining and metal working, has been attributed recently to a Bantu people of about 400 to 500 years ago, we now have in the Mumbwa cave evidence that metallurgy was being actively prosecuted in the Zambezi watershed thousands of years ago. Prof. Dart's conclusions may be soundly based, but in default of a more precise nomenclature for the implements in accordance with the generally accepted classification of South African stone age cultures, they are difficult to appraise. Implements of "late stone age type" in South Africa might be of any date. Nor is it possible to say that the smelters' culture is of Bushman origin on the evidence of burials which might be intrusive or explicable in other ways, unless the proof of their contemporaneity is more convincing than has been shown at present. More precise information as to the type of the furnace, which differs from that of the Bantu, may furnish some clue. If further examination of the data supports Prof. Dart's dating, this is a discovery of first-rate importance; in any event it is extremely interesting.

AUGUST ANDRÉE started from Danes Island, Spitsbergen, on July 11, 1897, with two companions, Drs. Strindberg and Fraenkel, to drift across the north pole by balloon. Ample supplies of food and ammunition were taken, the capacity of the balloon was increased by 300 cubic metres to 4800 cubic metres and the fabric strengthened by additional coats of varnish, but the risks were clearly great. Andrée sent messages by pigeons up to July 13, when their position was lat. 82°, long. 15° E. After that, nothing was heard of the party. Now, after an interval of thirty-three years, comes the report that the bodies of Andrée and one of his companions have been found on White Island, Franz Josef Land. It seems that a party from the Norwegian expedition carrying out investigations in Spitsbergen and the Arctic Ocean under Dr. Horn landed on the south-west of White Island on Aug. 6 and found traces of a camp near the coast. Further search led to the discovery of a boat and sledge, with notebooks, instruments, and other equipment marked "Andrée's Polar Expedition, 1897", and near by was Andrée's body. Another body was found some distance away and between some great stones in a cleft in the rocks. Both bodies have been well preserved by the intense cold, and their discovery is thought to be due to the unusual warmth of the present season. The remains of the expedition have been put on board the *Bratvaag*, the ship carrying the Norwegian expedition, which is due to return to Tromsö early in September.

THE preservation of memorials to famous men of science should be regarded as a duty. We are glad, therefore, to record that the tomb of Sir Humphry Davy in the old cemetery of Plainpalais in Geneva, which had fallen into disrepair, has not only been renovated but also that arrangements have been made for it to be suitably cared for in the future. Davy died in Geneva on May 29, 1829, while on his way home from Rome, and the funeral, arranged by de Candolle, the eminent botanist, was attended by a large number of the citizens of Geneva. Last year on the centenary of Davy's death the Faculty of Science of the University of Geneva visited his tomb and laid a wreath upon it. Through Dr. R. Fleming, of the Physiological Laboratory, Geneva, the attention of the Royal Institution was then directed to the state of the monument, and, thanks to the action of that body and the collaboration of Sir Humphry Davy Rolleston, it has been possible for a complete restoration of it to be carried out.

ACCORDING to a recent *Daily Science News Bulletin* issued by Science Service, Washington, D.C., a curious phenomenon was recently observed by the General Electric Company engineers who operate the broadcasting station WGY (Schenectady, U.S.A.). Having solved the problem of broadcasting waves in the broadcast band with 200 kilowatts, they attempted to broadcast waves of short wave-length using similar large power. With a power of 35 kilowatts brilliant brush discharges flashed and wavered round the antenna when the carrier wave was modulated with the current from the microphone in the studio. The carrier wave alone had no effect on the air near the antenna. It was only when it was modulated that violent corona effects were observed. These discharges caused the air to vibrate and produced noises like thunder which roughly reproduced the music. The antenna apparently acted like a gigantic loud speaker. If allowed to continue it would doubtless have arced across the insulators, fused the copper wires, and broken the antenna. To prevent this effect the wires were replaced by much thicker ones. Large hemispheres were also placed at each end of the antenna. This diminished the electric stress on the air near the conducting surfaces and 35 kilowatts of power are now successfully modulated by WGY on short waves without the formation of corona flashes.

THE overhead line from Luton to Bedford which was put into operation on May 29 last gives a good idea of the British 'grid' scheme which is rapidly being erected in many parts of the country. It consists of six steel cored aluminium line conductors and one overrunning steel cored aluminium earth conductor for lightning protection. Each line conductor consists of thirty aluminium strands surrounding seven steel strands. The insulators have nine discs, each ten inches in diameter, in series, which are suspended from the cross arm ends on straight line galvanised steel lattice towers. The towers vary in height from 72 ft. to 98 ft., and their bases vary between 14 ft. and 25 ft. square. The normal span is 900 ft. and the sag of the conductors is about 22 ft. From the æsthetic point of view little can be said for or against them, but as the transmission voltage is 132,000 they add to the risks of air navigation. In London itself it now seems quite certain that the cables will be put underground. The Italian Pirelli Co. has laid oil filled cables underground and found experimentally that they were satisfactory at pressures of 220 kilovolts. The Central Electricity Board began installing double circuit oil filled cable lines between Eltham and Deptford to work at the standard pressure of 132 kilovolts. It looks therefore as if all the main difficulties in the way of the grid transmission scheme are being overcome.

IT is highly probable that railway electrification would make much more rapid progress if it were not for the high capital outlay required. It is owing to this heavy outlay that many railway engineers are considering the possibility of using Diesel electric trains on British lines. In a brochure issued by Sir W. G. Armstrong Whitworth and Co., information is given of the advantages and growing popularity of this kind of traction. Armstrong-Sulzer Diesel electric motor coaches have been in service for more than five years without needing any overhaul. These motor coaches can be used for twenty hours out of the twenty-four and can run twice as many miles per annum as a steam locomotive. No time is required for lighting up and steam raising, and fuel for twenty-four hours' service can be pumped into the fuel tank in a few minutes. Economies can be effected when coasting down a long incline by stopping the engine. It is stated that a saving of several million pounds per annum on fuel alone could be effected by adopting this system on British railways. For the Russian State railways Diesel electric locomotives of this type have been made, having a working weight of 135 tons and of 1500 brake horse power. They are also used on one of the Tunisian railways, the Buenos Ayres Great Southern Railway, and the Swiss Federal Railways. We learn from *A.E.G.* (Allgemeine-Elektricitäts-Gesellschaft) *Progress* for August that this firm has had two petrol 150 horse power engine cars running on the Brazilian Central Railways since 1925, and that since then others of larger size have been supplied to the same railway. The Diesel electric locomotives have excellent running 'characteristics', there is practically no vibration, and the engines run noiselessly.

MR. G. STEVENSON TAYLOR gave the Gustave Canet Memorial Lecture before the Junior Institution of Engineers on the subject of industrial accidents, their cause and prevention. Mr. Taylor estimates that the total amount of compensation paid to workmen for accidents alone, apart from compensation for industrial disease, was nearly $6\frac{1}{2}$ million pounds in 1928: to this must be added the cost of administrative expenses as well as medical and legal costs. He thinks that this burden on industry could be materially reduced if the problem were attacked in the right spirit and on right lines. From information obtained by inspectors and others under the Factory Acts, he pointed out that more than 50 per cent of the accidents and more than 70 per cent of the fatalities were due to causes not

connected in any way with the use of machinery. A large number of accidents occur through persons falling over objects on the floors, and he urged the importance of clearly marked alleyways. It is also found that the percentage of accidents is greater during the winter months when the daylight hours are short. He considers that the personal factor in accidents is evidenced in carelessness, inattention, and want of thought. More recent studies than those reported by Mr. Taylor show that the personal factor involves much more than is suggested above. The work of Prof. M. Greenwood and his colleagues has shown statistically that the genesis of multiple accidents under uniform external conditions is an affair of personality and not determined by any obvious extrinsic factor. Later, Farmer and Chambers have produced evidence in favour of the view that there are people who have a definite measurable tendency to have accidents. This tendency may not necessarily be related to states of consciousness over which the person has control and cannot be adequately described by the moral judgment implied in such terms as carelessness or want of thought.

SOME years ago the idea was current that stone age man was a typical savage of a low grade of intelligence and the merest rudimentary forms of culture. We are now perhaps only just beginning to appreciate the significance of the stage of development of his brain, and to discern the skill and ingenuity that went to the fashioning of a stone implement and its adaptation to the needs of daily life. An interesting point bearing upon this aspect of relics of the stone age is discussed by Mr. Reid Moir in a communication entitled "Stone Implements from a New Angle", which appears in the *Journal of the Ipswich and District Natural History Society*, vol. 1, p. 2. With sound common sense, Mr. Reid Moir argues against the views of archæologists who hold that because the number of objects of material other than stone diminishes as the time series ascends until they disappear, therefore the earlier races of man employed no material except stone. He maintains that this takes too low a view of the intelligence of early man, and goes on to argue that both the nature of the material, that is, wood, bone, and ivory, and the conditions of deposit of the implements are such as to make it improbable that anything but the most durable material would survive except in such favourable conditions as are afforded by the French palæolithic caves. Yet even so, as he points out, we have the bone implement associated with Piltdown man, as well as other specimens for which a high antiquity is claimed. Mr. Reid Moir gives a useful hint to archæologists when he points out that the great majority of stone implements are implements with which other implements, now vanished, would be fashioned, As to the deeper significance of this dictum, we recommend consideration of Mr. Reid Moir's experiments in the practical use of stone implements, which the student might emulate if he can acquire the necessary dexterity and patient persistence.

FURTHER details of the International Zoological Congress have just been received, rather late in the day, as the Congress opens at Padua on Sept. 4. There will be an informal gathering at the Hotel Storione at 9.30 P.M. on Wednesday, Sept. 3. The opening ceremony will be at 10.30 A.M. on Thursday, at the University, when Dr. M. Caullery will give an address on genetics and evolution. The sections will meet in the afternoon and during such further afternoons or mornings as are not otherwise occupied. General meetings will be on the afternoon of Friday, Sept. 5, and the mornings of the following Saturday, Monday, Wednesday, and Thursday. Sunday, Sept. 7, will be filled with an excursion to the Lagoon of Venice. Shorter excursions during the meeting will be to the Royal Villa at Strà, to Rovigo, including a visit either to Count Arrigoni's ornithological collection or to Petrarch's house at Arquà, and to Abano. From Friday to Sunday, Sept. 12–14, there will be an excursion to the Lagoon of Comacchio, Badia di Pomposa, Bonifica di Codigoro, Ferrara, Bologna, and Ravenna. Favourable terms have been arranged at the hotels of Padua, and the Italian State Railway will issue return tickets from any frontier station or port to Padua at a reduction of 30 per cent. An exhibition of optical and other scientific instruments by Italian and foreign firms has been arranged. The address of the Congress is Via Loredan 6, Padova.

IN a pamphlet entitled "How Unemployment Might be Prevented", Capt. J. W. Petavel, formerly lecturer on "The Poverty Problem" at the University of Calcutta, advocates the formation of labour colonies or guilds as a solution of the unemployment problem. The basis of the proposal is that members of the guilds would undertake the direct production of most of their requirements, and the scheme is worked out to suit both Indian and European conditions. The author holds that the scheme would greatly increase the well-being of the Indian peasants, whose agricultural output is low, but whose needs are simple. In Europe it is suggested that the labour colonies might if necessary be modified so as to allow the workers to put in part of their time in ordinary factories and part in work at the colonies. In support of the scheme the success of a Swiss colony is cited. This has been organised on a self-supporting basis for 'unemployables', who can earn their keep at the colony together with a small surplus which is paid them on leaving. Educational colonies are also advocated for young persons up to eighteen years of age, who would spend half their time at school and the other half in productive employment at the colony, bringing back produce to their homes in lieu of wages.

AN important Congress of representatives of Czechoslovakia and Rumania was held at Krakow last December, for the purpose of discussing common interests in the protection of Nature. The *compte rendu* of the Congress, which has just been published, illustrates the necessity and the value of co-operation in such matters. The chief objective of the meetings was the attainment of agreement especially in regard to the national parks lying on the borders of the countries concerned, for the creation of a great boundary reserve in the mountain range of Czywczyn, and for the protection of the valley of the Dniester.

No less than fifty-three resolutions were agreed upon, perhaps the most important being those concerned with the setting-up of a permanent Commission representing Rumania, Czechoslovakia, and Poland, to deal with common problems and to endeavour to obtain general laws applicable to the three States, but allowing possibilities of modifications in detail to meet special needs in any particular territory. Other resolutions signified areas suitable for reserves, and pleaded for the protection of the forests, which are gradually disappearing, of rare animals and plants, for the reasonable regulation of fisheries in the boundary reserves, and of sport.

WE have received the annual report for 1928–29 of the National Institute for Research in Dairying, University of Reading. The Institute's home is four miles from Reading at the Shinfield Manor House; this was acquired in 1923 and adapted at a cost of £30,000, and a considerable balance of this sum still remains to be raised by public appeal. The report reviews the work of the Institute during the year, giving summaries of papers published by the staff during the period, and forecasts some of the investigations to be carried out in the future.

THE Ministry of Health has issued to councils of counties and county boroughs in Great Britain a "Memorandum on Cancer as a subject for the attention of Local Authorities" (Cancer · vii., *Circular* 1136). Its object is to suggest the desirability of local authorities acquiring more complete knowledge of the reactions between cancer and the local community, with the view of devising such local ameliorative measures as may be necessary and practicable. A scheme of methods of investigation, appropriate action, and co-operation with other authorities is suggested.

THE summer issue of *Sunlight*, the journal of the Sunlight League (Vol. 2, No. 2), contains articles urging that greater use should be made of the healing virtues of the sun's rays, particularly in England. Sir Bruce Bruce-Porter and Dr. Eidinow write on ultra-violet and other rays in health and disease, the Marchioness of Aberdeen and Temair on open-air village settlements, and Dr. Saleeby on the children's home at Chailey Heath, Sussex, which locality he maintains need not fear comparison with Leysin, and is far superior to Berck, the most celebrated sun-cure place in France.

THE *Journal of the Cancer Research Committee of the University of Sydney* for May (Vol. 2, No. 1) contains articles of considerable interest. Prof. Welsh writes on the classification and characters of the endothelial new growths, Mr. Mankin discusses micro-methods of chemical analysis, describing methods for the estimation of molybdenum, potassium, sodium, calcium, and chlorides, and Mr. Gower Stephens deals with the radiation treatment of brain tumours. From a small number of cases of brain tumour treated with X-radiation, experience shows improvement which is usually prompt and definite.

The Carnegie Institution of Washington has published a new edition (April 1930) of its "Classified List of Publications." This useful volume of 207 pages contains a chronological list of the Institution's publications, a subject index, with brief summaries of the most important works, and an authors' index. It is impossible to indicate here the variety or importance of the contributions to knowledge so listed, but an indication of the extent of the catalogue is given by the fact that the subject index is arranged under twenty-seven branches of science. Such books as are not out of print are available to correspondents at prices approximating to the cost of publication, and price-lists or classified lists as issued will be sent to scientific workers on the receipt of the requisite address.

THE Liverpool Electric Cable Company, Ltd., of Bootle, Liverpool, has sent us a catalogue of low tension paper insulated cables. All the cables described in this catalogue are manufactured in accordance with the regulations of the British Engineering Standards Association and the components of the cables are in accordance with the B.E.S.A. specifications.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant lecturer in chemistry at the Brighton Technical College—F. W. Toyne, Secretary, 54 Old Steine, Brighton (Sept. 2). A lecturer in mechanical engineering at the Norwich Technical College—The Principal, Norwich Technical College (Sept. 3). An assistant organiser of agricultural education under the Wilts County Council—The Clerk of the Wilts County Council, County Offices, Trowbridge (Sept. 6). An instructor in the department of navigation of the Sir John Cass Nautical School—The Principal, Sir John Cass Nautical School, Jewry Street, E.C.3 (Sept. 9). An assistant in the Barnato Joel Laboratories, Middlesex Hospital, for radiological research bearing upon the treatment of malignant disease—The Dean, Middlesex Hospital Medical School, London, W.1 (Sept. 13). An inspector under the Ministry of Agriculture and Fisheries, for the purposes of the Diseases of Animals Act, 1894–1925—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1. (Sept. 15). A demonstrator of biology at Guy's Hospital Medical School—The Dean, Guy's Hospital Medical School, London Bridge, S.E.1 (Sept. 20). An expert hydrobiologist for fisheries investigations in Turkey—Mr. E. C. Weberman, Beyoğlu, Sira Servi 4, Istanbul, Turkey (Oct. 15). A Pilkington fellow in cancer research in the University of Manchester—The Registrar, The University, Manchester (Nov. 15). A lecturer in physics at University College, London—The Secretary, University College, Gower Street, W.C.1. A lecturer on surveying and geodesy at the Regent Street Polytechnic—The Director of Education, The Polytechnic, Regent Street, W.1. Teachers of engineering drawing, heat, electricity and magnetism, mechanics and hydrostatics at the Croydon Polytechnic—The Principal, Central Polytechnic, Croydon. A laboratory steward and lecture assistant in the chemistry department of Goldsmiths' College—The Warden, Goldsmiths' College, New Cross, S.E.14.

Research Items.

Cancer of Lip and Skin.—Cancer of the lip, tongue, and skin is the subject of a report by Dr. Janet Lane-Claypon for the Ministry of Health (*Reps. on Pub. Health and Med. Subjects*, No. 59. London: H.M. Stationery Office, 2*s.* net). Cancer of the skin and of the lip is a readily curable disease if promptly diagnosed and treated. The results secured by radio-therapy appear equal if not superior to those obtained by operation, reaching 80 per cent or more of cures in the case of skin cancer. Cancer of the tongue, on the other hand, is far less amenable to treatment, either by operation or by radium. As regards causation, evidence is accumulating that the actual cancer is preceded by some apparently simple and harmless condition, such as a pimple, wart, mole, etc. A proportion of skin cancers is known to be associated with certain occupations involving contact with soot, tar, mineral oils, arsenic, and similar substances. As regards cancer of the tongue and lip, this is known to be frequently causably connected with syphilis and with smoking, but there is no evidence that the simple inhalation and exhalation of tobacco smoke are causative.

Comparison of Left and Right Ovaries.—In the whole animal economy, no organs lend themselves more readily than the ovaries to the study of quantitative and qualitative functional comparison, that is, to a comparison between the activity of one organ situated on one side, with another situated on the other side, of the body. In a preliminary note published in the *Rendiconti della Reale Accademia delle Scienze dell' Istituto di Bologna* (1929), Prof. Pasquale Sfameni shows that, as regards the ovigenic function, with cows, rabbits and women, the right-hand ovary predominates over the left. In the case of women, this predominance weakens as age increases up to thirty-five years, after which it becomes reversed. As regards the fœtus, this has the greater weight if generated by the right-hand ovules. Multiple corpi lutei are more frequent as the period of genital life advances, the superiority in this direction being shown by the left-hand ovary.

Effect of Cold on Sea Life. The second and third parts of the recent Report of the Danish Biological Station to the Ministry of Shipping and Fisheries (35; 1929), by H. Blevgad and A. C. Johansen, give accounts of the effect of cold on certain animals, the first dealing with the littoral invertebrates, the second with porpoises, fish, and crustacea. The winter of 1928–29 was specially severe and its effects were felt by many animals. It is shown that this prolonged frost had a pronounced effect on the littoral fauna, but some forms were much more resistant than others. The bottom animals are particularly exposed to the dangers of being killed in ice winters in the coastal belt between 0 m. to c. 1 metre's depth, especially in places which are liable to be left dry at low tide. The mussel *Mytilus edulis* suffered badly, also the cockle *Cardium edule* and the oyster (*Ostrea edulis*). Dr. Johansen notes the large numbers of porpoises dead in the Bornholm Deep, having probably fled from the ice in the Belt Sea. Only in areas of slight extent was there any wholesale destruction of fish such as cod, haddock, plaice, and flounder, and this probably chiefly owing to lack of oxygen near the bottom. The eel was the fish which suffered most, although in no locality was the stock wholly eliminated. Many smaller fishes besides crabs, lobsters, and shrimps also died.

Californian Commercial Fish Catches.—*Fish Bulletin* No. 20, "The Commercial Fish Catch of California for the Year 1928" by the staff of the Bureau of Commercial Fisheries of California (Division of Fish and Game of California, 1930) contains a large amount of information concerning a variety of commercial fishes and crustaceans. This is the second of the special bulletins dealing principally with monthly tables, and it is hoped to continue this annually, including in addition summaries of other classes of fisheries statistics collected by the Bureau. The chief features of 1928 were a continued increase in the amount of fish used for canning as opposed to utilisation in fish markets, the sudden development of a mackerel canning industry on a large scale, continued indications of the failure of the local fishing banks on the narrow continental shelf to supply the increasing demands for fish, and in consequence an increasing dependence on distant and foreign areas, extension of the tuna fishing area to far below Cape San Lucas, importation of albacore from Japan and Hawaii and, finally, the commercial utilisation of sword-fish. The bulletin begins with a useful list of the common and scientific names of the fishes, crustaceans, and mollusks, after which come short chapters on the most important species. The sardine is easily the first, the total catch being 2½ times that of the rest of the fish combined. Mackerel comes next, having risen from the tenth place in 1927 to second in 1928, due to canning. The rest are much the same as in former years.

Japanese Fresh-Water Rhabdocœlids.—Dr. K. Okugawa gives an interesting list of these flatworms in his paper "A List of the Fresh-Water Rhabdocœlids found in Middle Japan, with Preliminary Descriptions of New Species" (*Memoirs of the College of Science*, Kyôto Imperial University, Series B, vol. 5, No. 1, Article 4, 1930). No details were hitherto on record relating to the fresh-water species of this group, although certain cosmopolitan forms were known to be abundant in the rivers, ponds, and lakes of Japan. The author finds that the rice-fields of Middle Japan are specially favourable situations for these worms, the area containing warm and fertile water from May to October. Thirty-one species belonging to nine families are recorded, with notes on their structure and distribution. Six new species and two new varieties are described. Many of these Rhabdocœlids are very abundant in ditches and ponds as well as in the rice-fields. The research, extending over two years, was carried out chiefly at the Otsu Hydrobiological Station on Lake Biwa under the supervision of the Director, T. Kawamura.

The Mid-Atlantic Ridge.—The origin of the Mid-Atlantic Ridge, one of the most remarkable features of the globe, is a much-disputed problem. Haug regards the Ridge as a median anticline formed by the beginning of crumpling in the great 'geosyncline' of the Atlantic. For Taylor, Wegener, and others, it is a strip of the original crust from which the continents on opposite sides have drifted away. Thus, as in the case of the African Rift Valleys, there are two diametrically opposed hypotheses in the field: one involving compression, the other tension. Dr. H. S. Washington now enters the field via the petrology of St. Paul's Rocks, a group of four rocky islets lying on that part of the Ridge which runs nearly east and west just north of the equator (*Jour. Maryland Acad. Sci.*, vol. 1, No. 1, Jan. 1930). Unlike most of the Atlantic islands, St. Paul's Rocks are not volcanic, but are composed of a plutonic ultrabasic rock—a wehrlitic dunite—that has been metamorphosed by pressure. Washington therefore regards

"lateral pressure as the sole competent cause of the uplift of this part of the Ridge, which is quite in accord with the known condition of instability and present-day seismic and submarine volcanic activity of the region". To account for the peculiar shape of the Ridge, Washington is tempted to apply the torsional hypothesis of Prinz, suggesting an eastward movement on the south and a westward movement on the north.

Remarkable Series of Earthquakes at Ito (Japan).—Ito is a watering-place on the west coast of Sagami Bay. For two months since the middle of last February the town has been shaken by almost incessant earthquakes, none of them of destructive intensity, though a few were strong enough to overturn grave-stones and crack plaster-walls. The earthquakes have been studied by Prof. Imamura and three of his colleagues in the Seismological Institute (*Proc. Imp. Acad., Tokyo*., vol. 6, pp. 190-193; 1930). A network of five seismograph stations was formed round the epicentral area. The total number of shocks recorded from Feb. 13 to April 11 was 3684, the maximum daily frequency (of 209) being reached on Mar. 9. Comparing the hourly frequency of the shocks with the tidal phases at Misaki (on the north coast of the bay), it was seen that the shocks occurred in groups coinciding with periods of low water. The most interesting result is one due to Mr. Nasu that, with a few exceptions, the foci of the earthquakes were confined to a conical region of the crust, the apex of the cone being at a depth of 6 km., while the base is a circle of about 2 km. radius on the sea-bed in the inlet of Ito. The nearer the earth's surface, the denser is the clustering of the foci. This distribution seems to suggest the presence of a hidden extinct volcano with the above-mentioned cone as its crater.

Distribution of Earthquakes in the East Indies.—Dr. S. W. Visser has recently published a useful discussion of the distribution of earthquakes in the Dutch East Indies during the years 1920–26 (*Verhand. Konin. Magn. en Meteor. Obs. te Batavia*, No. 22; 1930). In this interval 3310 earthquakes were recorded, the great majority very slight, though 35 were registered all over the world. Of the total number, only 244 had an inland origin. A large district, including Sumatra east of the Barisan Mountains and the whole of Borneo, with the exception of the east coast, is practically aseismic. On the other hand, earthquakes are frequent all along the coasts of the Indian Ocean from Atjeh to Timor, in the north of Celebes, in a small central area of the Moluccas, including Boeroe, Ceram, and Banda, and the northern portion of New Guinea. As a general rule, the epicentres of submarine earthquakes lie on the steep slopes of the oceans and deep seas, while those of land earthquakes are closely connected with existing fractures.

Magnetic Tables for the United States.—In the *United States Magnetic Tables and Magnetic Charts for 1925*, issued by the U.S. Department of Commerce, Coast and Geodetic Survey (Serial No. 453, 1929, price 60 cents, pp. 136, 4 maps), complete revised data are given concerning the distribution of magnetic force over the United States, for the epoch 1925; the publication supersedes the Tables and Charts for 1915 given in *Special Publication*, No. 44, now out of print. It contains the observed values of declination, dip, and horizontal intensity for all places in the United States at which reliable observations have been made, together with the reduced values for Jan. 1, 1925; tables giving repeat observations at stations occupied between January 1917 and December 1928; tables giving the secular variation; and isomagnetic charts for declination, dip, and the horizontal and vertical intensities. The charts measure 20½ in. by 26½ in.; the lines of equal declination and dip are given for each degree, and of equal annual change for each minute of arc; the lines of equal intensity are given for each 1000γ, and of equal annual change for each 10γ. The maps extend northwards to about latitude 50°; Alaska is not included. The tables occupy 124 pages, 98 of which are reproduced from typewritten sheets by photo-lithography.

Stark Effect.—An investigation of the electric fields needed before lines of a spectrum appear which are normally forbidden by the selection rule for azimuthal quantum numbers, is described by Y. Ishida and T. Tamura in a *Scientific Paper* (No. 241) of the Tokyo Institute of Physical and Chemical Research. This effect, which is distinct from the splitting of lines already present in the absence of a field, has been studied for helium in a tube of the Lo Surdo type. The field strength below which these 'forbidden' lines are still absent is greatest when they involve no change in azimuthal quantum number (k), falls to zero for the normal change of unity, and increases again, although not to the same extent as for $\Delta k = 0$, for the lines for which Δk is 2, 3, and 4. For a transition to a definite final state from an initial state in which only the initial total quantum number (n) is variable, the field required falls off rapidly with increase in n; for example, 87 kilovolts per cm. are needed to bring out the line $2S$-$3S$, but only 3·2 kv./cm. for the line $2S$-$6S$. A disappearance of lines in very strong fields, of the order of a million volts per cm., has also been recorded recently by Traubenberg, Gebauer, and Lewin, with the Stark effect of the Balmer lines of hydrogen (*Die Naturwissenschaften*, vol. 18, p. 417; 1930).

Electrical Heating in Laboratories.—In the April number of *Helios*, an export electrical trade journal published in Leipzig, there is an illustrated article showing many heating devices for use in laboratories. Laboratories for general analytical work are sometimes built at a distance from public gas mains. If there is no great demand for gas for smelting and muffle furnaces, the cost of laying down gas mains over long distances may be unduly heavy. To obviate this expense all kinds of makeshifts have been tried, such as acetylene Bunsen burners and spirit or petroleum Bunsen burners. The cost of service for the acetylene burners is low although their initial cost is high. On the other hand, spirit or petroleum burners cost little but the charge for the fuel is high. The latter system therefore is only used in very small laboratories. The question of using electric heating in laboratory equipments has been little considered in Great Britain, although it possesses many advantages. The heat can be applied exactly where it is wanted and there is much less risk of explosions. The high radiation and convection losses from flames are avoided and despite the high cost of electricity the running cost in service may be actually less than when gas is used. Up-to-date water baths and drying cabinets heated electrically are shown, in which the consumption of energy is a minimum. In the drying cabinets the heating member is built inside the heat protection jacket, so it is easy to maintain a constant temperature. For laboratories in which much high class work has to be done, small test tube furnaces are specially suitable. Only the lower parts of the test tubes are heated and there is no useless waste of electric energy. There is no risk in heating explosive or highly inflammable material. A small crucible

furnace is shown suitable for the incineration of analytical precipitations. Permanent temperatures up to 1200° C. can be obtained without any trouble. The furnaces are furnished with an external nickel protective jacket.

Chemistry of Immunology.—*Science Progress* for July contains an article by Dr. W. O. Kermack on some recent advances in the chemistry of immunology in which the part played by non-protein compounds is more especially dealt with. These carbohydrates, called haptenes, resemble proteins in reacting with homologous antisera even in very great dilution, but they are not antigens since they cannot produce antibodies. It appears that Ehrlich's general idea of haptophores may have a real significance, and that the molecular groupings to which he gave that name may, in certain instances at least, be given a definite chemical configuration.

Iron Carbonyl.—With reference to the note on the formation of iron pentacarbonyl in a cylinder of compressed coal gas, which appeared in NATURE of June 7, p. 873, Mr. J. E. Mason informs us that the possibility of the formation of iron carbonyl in these circumstances was recognised by Dr. Bedford in 1912. On the experimental plant at Sleaford (Lincoln) for the hydrogenation of oils by the Bedford-Williams process, it was made a rule not to store hydrogen in the large laboratory cylinders for more than a day or two if the carbon monoxide content of the gas exceeded a few per cent. It is not stated that the actual production of iron carbonyl was experimentally demonstrated, as in Friend and Vallance's communication.

Atomic Weight of Tantalum.—The accepted value for the atomic weight of tantalum, 181·3 or 181·5 (the values adopted in different countries vary since the machinery of the International Committee on Atomic Weights broke down), is based on results which are not in satisfactory agreement. In the June number of the *Journal of the Chemical Society*, Kolar Ramakrishnaiyer Krishnaswami describes experiments on the determination of the ratios $TaBr_5$: 5Ag : 5AgBr and $TaCl_5$: 5Ag : 5AgCl, in which twenty-four closely agreeing results pointed to the value 181·36 for the atomic weight of tantalum. Modern methods were used and great care was taken in the purification of the materials.

Vitamin-D.—It is now known that vitamin-D is produced by the irradiation of ergosterol and that the latter is the only sterol which gives rise to it. Previously it was thought that cholesterol was the provitamin, but experiments seem to have proved that its activity is due to a content of about 0·05 per cent of ergosterol in the cholesterol. Several investigations have been made on the effect of monochromatic light on cholesterol. In the June number of the *Journal of the American Chemical Society*, Marshall and Knudson describe some experiments made with ergosterol. They conclude that the rate of production of vitamin-D is proportional to the first power of the light intensity, that it is directly proportional to the number of light quanta absorbed by ergosterol and independent of the wave-length, and that the quantum efficiency is 0·3 molecules of vitamin-D per quantum absorbed. Vitamin-D absorbs in the same wave-length region as ergosterol and is destroyed by light of the same wave-length as that which forms it. The highest concentration of vitamin-D which can be produced by direct irradiation of ergosterol is 35 per cent. This is an absolute maximum and the probable value is lower.
